"Finally, this appeal is made to all,—to those who have little, that they may give of that little, and to those who are blessed with the stewardship of this world's goods; and both are most earnestly invited to provide for the distresses of the indigent and the suffering; and thus to be laying up for themselves 'treasures in heaven where neither rust nor moth doth corrupt.' If you yourselves are free from the fear of want, Oh! listen to the cry of the destitute, that feeble cry which is so frequently stifled by feelings of a most time-honoured description, and which has so often to be revealed by the kind detective hand of some neighbour friend; Oh! listen to the feeble accents of grief unspeakable—'Oh! give relief, and heaven shall bless your store.'

"William Newnham,
Treasurer and Hon. Secretary."

"The following is a selection from cases relieved during the past year: and the financial statement for the year ending June 30th, 1849:—

"1. The widow and four orphan children of a respectable practitioner in Dorsetshire. This case had been materially aided by the neighbouring practitioners and friends; there were six children left, the eldest of which was accidentally drowned. One is provided for; the remainder were aided from your fund, and one of the boys has been since elected into the Orphan Asylum of Clapton.

"2. A widow and six children, with an income of only 0*l*. a year. These have been saved from ruin and absolute starvation during the year.

"3. A physician and his family, in a state of the utmost destitution. He himself had been once an active and a literary man, but was deprived of the means of earning his living by mental malady; his little all was spent, and although restored to health, his position was lost, and he was reduced to poverty in its most aggravated form.

"4. A practitioner, who was supported during the last months of a pitiable existence, and his destitute widow and orphans have been aided in their efforts to keep themselves from absolute want. This case had actually been relieved by a Board of Guardians.

"5. A Medical man, supported through the most trying circumstances, and enabled to restore himself to his position.

"6. A physician of eminent literary attainments, yet the child of misfortune, had been driven to attempt suicide by destitution of the most appalling character, absolutely saved from destruction.

"7. The family of a most respectable practitioner; the father died from acute malady; the son came home from the hospital, where he had been noticed as a young man of distinguished talent, to take his father's practice; he fell ill from fever, and was confined to his bed for three months; his sisters, who kept a school, lost that school from fear of fever; their distress was much aggravated. They were relieved and comforted.

"8. A young widow, whose husband's life had been cut short by fever caught in the discharge of his duties at Liverpool. She was aided to emigrate, in the hope of finding in another hemisphere employment in tuition for talents of no ordinary character.

"9 and 10. Physicians with families in a state of the most abject poverty. They were also aided to emigrate, and try their fortune in a new world."

MEDICAL NEWS.

Apothecaries' Hall.—Names of gentlemen who passed their examination in the science and practice of medicine, and received Certificates to practise, on Thursday, August 16, 1849:—William Clapham Cautley, Hedon, Hull; Thomas Brutton Kenderdine, Stafford; Thomas Edis; William Bellhouse Midwood, Manchester; John Adams Palin; Francis Henry Vertue.

Royal College of Surgeons.—The following gentlemen, having undergone the necessary examinations for the diploma, were admitted members of the College at the meeting of the Court of Examiners, on the 17th inst., being the last meeting of the Court this Session:—Messrs. John Abernethy Kingdon, Bank-buildings, City; Thomas Mills, Tipton, Staffordshire; Charles William Sadler Large, Camberwell; William Watts Thetford, Dublin; James Hannan, Limerick; Charles Caulfield Moore, Brimpsfield, Gloucestershire; and Bagley Thomas Hunter Bell, Pocklington, Yorkshire. At the same meeting of the Court, Mr. Thomas William Rimell passed his examination for naval surgeon; this gentleman had previously been admitted a member of the College, his diploma bearing date May 10, 1843.

Obituary.—On the 2nd inst., at Caen, Normandy, Henry Charles Duckle, of Pilham-hall, Gainsborough, Esq., M.D., in the 46th year of his age.—On the 18th inst., at 22, Charlotte-street, Leith, Walter Bruce, Esq., M.D.—On the 19th June, at Bagdad, John Ross, H.E.I.C.S., Surgeon to the British Residency there, eldest son of the late Dr. William Ross, Cambusmore, Sutherlandshire.

Death of Aston Key, Esq.—We have to announce the death of Mr. Aston Key, senior Surgeon to Guy's Hospital. Mr. Key was seized with cholera at his residence, St. Helen's-place, Bishopsgate, on Wednesday morning the 22nd inst., at half-past eleven, and died on Thursday at half-past seven a.m. He was in his usual good health on Wednesday morning; shortly after breakfast he appeared unwell; but, notwithstanding his indisposition, he saw and prescribed for his patients as usual, and in the evening was suffering severely from an attack of the prevailing epidemic, which terminated fatally on the following morning. Mr. Charles Aston Key was well known to the Profession as a scientific surgeon and successful practitioner. He was admitted a member of the Royal College of Surgeons on the 5th of January, 1821, and on the 30th of July, 1845, was elected by the "Fellows" a member of the Council of the College; he also held the appointment of Senior Surgeon to Guy's Hospital, and Surgeon in Ordinary to His Royal Highness Prince Albert. Mr. Key was the author of several contributions to the advancement of surgical science.

Mr. Henry James Johnson.—It is with sincere pleasure that we announce the convalescence of Mr. Henry James Johnson, the eldest son of the lamented Dr. James Johnson. We understand that he will resume his Professional labours next month.

University College.—Dr. W. B. Carpenter has been appointed Professor of Medical Jurisprudence.

Royal Dispensary for Diseases of the Ear, Dean-Street, Soho-square.—On Friday last the half-yearly meeting of this Institution took place at the Dispensary, Dr. Richards in the chair. The Secretary read a brief report of the proceedings, and the amount of subscriptions received during the last six months. The charity having been aided by the subscriptions of the Queen Dowager, the King of the Belgians, the Misses Tilney Long and others, at present the resources of the Dispensary were found inadequate to meet not only the claims upon the Charity, but also the increasing number of applicants for relief. During the last six months 458 fresh cases were entered on the books, and 88 discharged cured, many of which were of long standing. The Committee, therefore, appeal to the friends of the Institution and the benevolent, to render them assistance for carrying out these important objects. Votes of thanks were passed to Mr. Harvey, the Surgeon, and to Dr. Richards, for his kindness in taking the chair.

The Cholera.—Her Majesty's lighter Rochester sailed from Devonport last week with a large number of tents for the inhabitants of Megavissey, Cornwall, to live under, whilst their village is being cleansed; an application having been made by the Board of Health for that purpose, as the cholera is now raging to a great extent there.

The Apothecaries Company v. Morris.—An action has been brought by the above Company against Mr. Morris, qualified as a surgeon, for practising as an apothecary. Without calling witnesses, the defendant ultimately agreed to pay the penalty of 20*l*. and costs.

Public Health (Ireland) Bill.—A Bill for promoting the public health in Ireland, containing 155 clauses, has been printed for consideration during the recess. It was prepared and brought in by the Irish and English Secretaries of State.

The Profession.—From the list of gentlemen admitted members of the Royal College of Surgeons, as published in our last number, it will be perceived that no less than thirty-four qualified practitioners have been admitted in one week; including "Fellows," we have the list increased to forty-four; indeed, for some time past, the Board have had two

and three meetings a week for the examination of candidates. We may well exclaim, with the late Mr. Abernethy, who, on entering his lecture-room, was so astonished at the great number of students present as to express in audible terms, "What the Devil is to become of you all!" We may observe, *en passant*, that after the next examination for the "Fellowship," candidates will be examined as to their proficiency in Greek and Latin.

Medical Topography. — Dr. W. Freeman Daniell, the Author of some elaborate papers on the Bights of Benin and Biafra, has in the press a work on the Medical Topography and Native Diseases of the Gulf of Guinea; derived from the experience of some years' residence on the West Coast of Africa.

Currents of Electricity along the Wires of Telegraphs.—M. Baumgartner has been engaged in investigating the phenomena connected with the passage of natural currents of electricity along the wires of the electrical telegraphs, his investigations having been principally directed to the line of wires from Vienna and Gratz to Senmering. He proves that the needle rarely returns to its true zero: it is always subject to more or less deviation from the atmospheric current. The deviations are of two kinds:—one producing a deflexion of often 50°, the other varying from half a degree to 8°. The first are much less frequent; and they vary in direction and intensity in such a way that the law by which they are guided cannot be yet detected. The other, on the contrary, appears to obey a simple law: during the day it is from Vienna to the stations to the south of that city, and during the night in a contrary direction. The change in the direction appears to be accomplished after the rising and after the setting of the sun. When the air is dry and the sky serene the regularity of the current is very decided: it is not so uniform in cold and wet weather. M. de la Rive also has observed facts which completely accord with those of M. Baumgartner.—*Athenæum.*

Repulsive Force of Incandescent Surfaces.—M. P. H. Boutigny has lately proved that metals in a melted state have in a remarkable manner the repulsive force of incandescent surfaces, and that the tricks of fire-eaters and conjurors belong to a high class of physical facts. He made the following experiments:—He divided or cut with his hand a jet of melted metal of five centimetres, which escaped by the tap. Immediately he plunged the other hand into a pot filled with incandescent metal. Both hands came out of the ordeal unhurt. The precaution necessary to prevent the disorganizing action of the incandescent mass is to make the experiment with confidence; to pass the hand rapidly, but not too rapidly, in the metal in full fusion. The experiment succeeds perfectly when the skin is moist, and the dread usually felt at facing masses of fire supplies necessary moisture; but by taking some precaution we may become truly invulnerable. The following succeeds best:—Rub the hands with soap so as to give them a polished surface; then, at the instant of trying the experiment, dip the hands into a cold solution of sal-ammoniac saturated with sulphurous acid. The experiment has been tried by Boutigny with melted lead, bronze, and cast iron.

Development of Electricity by the Contraction of Muscles.—The experiment of M. Du Bois Reymond on the development of electricity by the voluntary contraction of the muscles has been much discussed on the Continent. MM. Despretz, Becquerel, and Matteucci have not been successful in producing the effects which were stated to have been obtained by M. Reymond, and attested by M. de Humboldt. M. de Humboldt has addressed a second letter to M. Arago, stating that at a new *séance* in the cabinet of M. Emile Du Bois Reymond the effects produced by M. Mitscherlich were most unequivocal, and fully established the truth of this new fact. "Occupied myself," concludes Humboldt, "for more than half a century in this class of physiological researches, the discovery which I have announced has for me a vital interest. It is a phenomenon of life rendered sensible by a physical instrument."

MORTALITY TABLE,

(Metropolis.)

For the Week ending Saturday, Aug. 18, 1849.

Causes of Death.	Total.	Average of Five Summers.
All Causes	2330	1008

TO CORRESPONDENTS.

"Cyclops."—Myopia may be produced by looking habitually at small and near objects, and concave glasses often increase the defect. We do not think that this disease naturally disappears in advanced life.

"A Young Anatomist."—The third nerve is certainly the principal motor nerve of the eye-ball; experiments on this nerve being difficult of execution, we are not surprised at our Correspondent's disappointment.

"Amator Veritatis."—Inquiry should be made of the Secretary.

"Obstetrician."—It would be a difficult matter to state when midwifery forceps were first used. Two kinds were, however, formerly employed in practice. One was armed with teeth, and was intended to extract the child without regard to any injury it might sustain. It is now entirely laid aside. The other was without teeth, and when used was covered with some soft material, to defend the fœtus from injury.

"Beta."—The appointment of army assistant-surgeons rests with the Director-General, Sir James M'Grigor.

"A College Member" is mistaken. The examination at Oxford is conducted not only *vivâ voce*, but by written questions.

"Rusticus."—The old corporation of Surgeons lost its charter from neglect of duty.

"Inquirer."—Relapses are frequent after operations on cancerous tongues.

"A Qualified Practitioner."—The regulations of St. Andrew's are, we believe, always enforced, except when a candidate is possessed of a diploma from the Colleges of London, Edinburgh, Dublin, or the Faculty of Physicians and Surgeons of Glasgow, or a license from the Apothecaries' Company; in which case, he has merely to present such diploma or license previously to examination for M.D.

"A Surgeon and Old Subscriber."—It is impossible for us to state the exact nature of the accident. Fractures of the neck of the scapula are liable to be mistaken for dislocations of the humerus downwards, the weight of the arms carry the limb downwards along with the glenoid cavity of the scapula, and a hollow is felt under the acromion.

"Londinensis."—Hippuric acid can be obtained from fresh urine by concentrating it in a gentle heat, adding so much hydrochloric acid as to produce an acid re-action, and setting it aside to rest when impure coloured hippuric acid is deposited in crystals. In the urine it is combined with soda or ammonia, from which it is separated by the mineral acid.

"Mem."—The mode in which electricity is distributed over the surface of a conductor is dependent on its figure. On a sphere it forms an uniform stratum of equal thickness all round; but on an ellipsoid, the stratum is thickest at the extremities of the longer axis.

"Chirurgus, Newport."—Any medical practitioner can obtain lymph on application to the Secretary of the National Vaccine Institution.

"A Subscriber."—All the information required by our Correspondent may be found in Dr. Golding Bird's Work.

"Mr. Philbrick, Colchester."—Communication received.

"F. S. Bexley, Kent."—The muscus pyxidatus is meant, a common little plant which grows on the banks of ditches, by wood sides, and in dry barren soils.

"Querist."—(1) Yes. (2) The surgical wards.

"Mr. Wm. Smith, Belper."—Letter received.

"An Old Subscriber, Cadogan-place."—If a person with only a German diploma practises as an Apothecary, he is liable to prosecution under the Apothecaries' Act; if as a Physician, the London College can punish him.

"Mr. Arthur Baillie, Upata, Venezuela."—Communication received.

"Mathetes."—(1) Yes. (2) Yes, if the Practitioner be a Licentiate of the Society.

"An Old Retired Physician."—Received.

ORIGINAL LECTURES.

LECTURES ON THE CHEMISTRY OF THE POISONS; OR, ON PRACTICAL TOXICOLOGY.

SHOWING THE APPLICATIONS OF CHEMISTRY TO THE DISCOVERY OF CRIME.

By H. LETHEBY, M.B., Lond:
Lecturer on Chemistry at the Medical College of the London Hospital.

LECTURE VI.

Applications of a Knowledge of the Chemistry of Sulphuric Acid to Medico-legal Purposes:—1st. In recognizing the Effects of Sulphuric Acid on the Tissues of the Animal Body; *Post-mortem* Appearances; Administration of Antidotes; Mode of proceeding in order to recognise the Presence of the Acid in Organic Compounds, as, first, in the Contents of the Stomach; Letheby's Process, Christison's ditto, Taylor's ditto; and, secondly, in the Tissues of the Body; Methods proposed by Letheby; Amounts of Acid yielded by the Natural Tissues; Devergie and Taufflieb's Process; Taylor's Objections thereto; Comments on the Looseness and Want of Precision in the labours of some Toxicologists.

GENTLEMEN,—We have been hitherto engaged in studying the chemistry of Sulphuric acid. Let us now see what practical applications can be made of the knowledge so obtained.

In most cases of poisoning by oil of vitriol, the chief parts of the evidence will be deduced from chemical facts. It is your duty, therefore, whenever you are called on to investigate these cases, to keep the chemistry of the subject in view, to seek diligently for the corrosive effects of the acid upon the body and clothes of the individual poisoned, and also to make a chemical examination of all relative matters which are likely to contain the poisonous agent. Much of what I have already said will, perhaps, serve to guide you in these inquiries; but still it will be advantageous, if we discuss this part of our subject a little more fully. And,—

1ST. WITH REGARD TO THE CHEMICAL EFFECTS OF THE ACID UPON THE TISSUES OF THE ANIMAL BODY.

At a former meeting, you witnessed the effects of sulphuric acid when it was poured upon the dead mucous membrane; and I have now to inform you that the very same effects are manifested when this acid is swallowed or permitted to run over the living animal tissues. You will find, therefore, that, when a strong solution of sulphuric acid is brought into contact with any delicate or highly organised part of the body, it produces effects which vary with the period of its operation; thus, the acid, at first, coagulates and whitens the albumen, or rather the epithelium, which exists upon the surface of the part, and then, acting for a longer time, it carbonizes, and subsequently dissolves the tissues of the part; while, if it should happen to become mixed with blood, it will coagulate this fluid, and convert it into a dark, tarry-looking compound. All of these effects are commonly observed in cases of poisoning by oil of vitriol; for instance, the whitening effect is generally manifested upon the lips, tongue, pharynx, and œsophagus, the parts over which the acid has flowed in the act of swallowing it. I should tell you, moreover, that the epethelium, thus acted on and disorganised, soon begins to peal off in long shreds, leaving the subjacent tissue red and somewhat inflamed. Indeed, there are cases on record in which the membrane so coagulated has been thrown off from the œsophagus, and vomited up in large flakes or tubular pieces resembling parchment. If, however, the parts upon which the acid has thus acted, have been exposed to the air, and allowed to become dry, the whitening effect is generally lost; for, under these circumstances, it rapidly changes into a dirty brown scab. It is common, therefore, in cases of poisoning by oil of vitriol, to find the lips and angles of the mouth covered with sores of the latter description.

On reaching the stomach, the acid at first exerts its coagulating action upon the walls and albuminous contents of this organ; but soon, in consequence of a more prolonged action, the poison operates corrosively upon the mucous coat; blood is thus set free which, by being blackened and coagulated by the acid, is converted into a dark grumous compound like thick porter or unstrained coffee. This compound is quickly discharged from the stomach; and, if you examine it carefully, you will find portions of coagulated albumen, together with strips of disorganised membrane, and dark slimy mucous abundantly diffused through it. All this is accompanied, as you may easily imagine, with an excruciating burning pain in the mouth, throat, and stomach. You will find, also, that shreds of albumen and dark-coagulated blood are copiously voided by stool, indicating that there has been a terrible disorganising action on the mucous surface of the intestines likewise. In fact, should the poor sufferer rally from these, the first effects of the acid, he is very likely to fall a victim to one or other of its secondary consequences, as ulceration of the stomach or bowels, scirrhus of the pylorus, chronic dyspepsia, or even starvation itself. Should he, however, succumb to the earlier effects of the poison, you will, on making a *post mortem examination* of the body, be almost sure to find some remains of the whitening effect of the acid upon the tongue and œsophagus. The exterior of the stomach will generally exhibit a multitude of vessels filled with black, acid, coagulated blood. Frequently, too, you will find that the poison has transuded through the parietes of the stomach and intestines, and has not only given an acid character to the fluid which lubricates the outer surface of these organs, but has also produced a violent inflammation of the peritoneal membrane itself. Again, on opening the stomach, you will find that its contents are dark-coloured and slimy; that its mucous coat is blackened and gorged with blood; and that its parietes are corroded, and, perhaps, in part, dissolved by the poison. It may even happen that the walls of the stomach are quite eaten through by it, and that the acid has attacked the surrounding viscera. Should the vitriol have passed beyond the pyloric opening of the stomach, you will discover some evidence of its corrosive action along the first foot or so of the intestinal canal; and the intestines will contain a dark porter-like fluid, in which you will readily perceive flakes of albumen and shreds of disorganised membrane.

And now with regard to the administration of Antidotes.— Your chemical knowledge, together with the facts which we have just witnessed, will indicate to you that the best remedies in cases of poisoning by oil of vitriol will be the most accessible; and, therefore, you will resort to such antidotes as white of egg, soap and water, chalk and water, or, better still, if at hand, a table-spoonful or so of calcined magnesia. All these substances act by engaging the affinities of the acid, and by forming compounds which are harmless to the tissues. Reference is made in some of our medico-legal works to the employment of the stomach-pump in these cases; but I trust that no man would be rash enough to use this instrument under such circumstances, unless he wishes to kill by abrading the œsophagus or by perforating the walls of the stomach. Indeed, you should always remember that, in cases of poisoning by the mineral acids or alkalies, you are not to think so much about the means of getting rid of the corrosive agent, as you are concerning the mode by which the virulent action of the poison can be most fully and promptly neutralized. Again, a great deal has been said respecting the use of alkaline carbonates and bicarbonates as antidotes to sulphuric acid; but I cannot understand that they possess any advantage whatever over the corresponding earthy compounds, and they are certainly open to two great disadvantages, viz., that they are not always at hand, and that their too liberal employment is very likely to produce effects which are quite as dangerous as those which result from oil of vitriol itself.

MODE OF PROCEEDING IN ORDER TO RECOGNISE THE PRESENCE OF SULPHURIC ACID IN ORGANIC COMPOUNDS.

(a) *In the Contents of the Stomach.*—To judge from the many instances of poisoning by sulphuric acid on record, it appears that the contents of the stomach do not commonly contain, under such circumstances, a very notable proportion of the acid. In fact, when we bear in mind, that sulphuric acid has a powerful affinity for albuminous substances; that the torments of the patient urge him to make use of large quantities of diluents; that the vomiting excited by the poison is profuse and constant; that the efforts of the medical attendant, and the results of putrefaction are very likely to neutralise any free acid which may escape expulsion, it will be evident to you that there is but a small chance of our being able to detect the acid in those matters which remain in the stomach after death; and, therefore, as Dr. Christison says, " the detection of sulphuric acid in complex organic mixtures, simple though it appears at first sight, is one of the most difficult problems in medico-legal chemistry." As I have already informed you, many toxicologists, including Orfila, Devergie, Simon, Christison, and Taylor have turned their attentions to this important subject, and the result of their investigations prove that a satisfactory process for the detection of sulphuric acid in organic mixtures has yet to be discovered. The process which I shall recommend to you is one which I have employed on many occasions with considerable success; and besides its being a very certain one, it possesses the advantage of being the means whereby other and widely different poisons may also be detected.

1st. You are to evaporate the contents of the stomach in a water-bath until they acquire a thick syrupy consistence; then exhaust them with strong spirit, (an alcohol, having the specific gravity of 834, will answer very well for the purpose,) and test the filtered liquor by means of a soluble salt of baryta. In this operation you will understand, that the alcohol merely dissolves free sulphuric acid, and leaves the neutral salts of this poison untouched. But,

2ndly. As the residue of this operation may still contain soluble sulphates, you are to digest it in water, then filter the solution, and test it for sulphuric acid in the ordinary manner.

3rdly. Should the Practitioner have administered chalk and water as an antidote, it is possible that the residuum of the last operation may still contain a considerable portion of sulphuric acid, in the form of sulphate of lime,—a salt which is but slightly soluble in water. In order to demonstrate the truth of this, you are to boil the aqueous residue for about an hour or so with an excess of a solution of carbonate of soda; by which means, if sulphate of lime be present, you will, in consequence of an opposite play of affinities, obtain a solution of sulphate of soda, and a precipitate of carbonate of lime. On filtering this liquor, acidulating it with nitric acid, and testing it with a salt of baryta, you can easily prove the existence of sulphuric acid.

By proceeding in this manner there will be no difficulty in detecting all the sulphuric acid which was present in the contents of the stomach; but remember, that your inquiries are not yet at an end,—for, although you may have found the acid in the suspected liquor, you must be guided by collateral circumstances in forming your opinion as to its source.

Notwithstanding that I strongly recommend you to adopt the preceding mode of analysis, as being, in my opinion, the most easy and certain, yet it is my duty to make you acquainted with a process which is considered, by Dr. Christison, to be the most eligible. He describes it as follows:—

(a) " *If the mixture be acid*, add distilled water, —if necessary, boil, filter, and test a few drops of the fluid with nitrate of baryta, followed by nitric acid. If there be no precipitate, the search for sulphuric acid is at an end. If a precipitate form, distil the fluid from a muriate of lime or oil bath at a temperature not above 240°, till the residuum acquire a thick syrupy consistence; and preserve apart the last sixth of the distilled liquor. In this liquor test for hydrochloric acid by litmus paper and nitrate of silver; and for acetic acid, by litmus paper and the odour and taste of the liquid. If these acids be not in the distilled fluid, they are not in the residuum. In a portion of this residuum

search for nitric acid, and in another portion for oxalic acid, by the processes for these poisons in complex mixtures. If all these acids be thus proved to be absent, it is most unlikely that the acidity of the mixture is owing to any other but sulphuric acid, especially in the case of the contents or textures of the stomach.

"Dilute now what remains of the syrupy extract, and add nitrate of baryta with nitric acid. If a precipitate fall, there is a strong presumption, that the acidity of the mixture was owing either to a bisulphate, or to free sulphuric acid. And between these, the question may be almost settled, first, by the probability or improbability of a bisulphate having come in the way, and, secondly, by the symptoms and morbid appearances. The result, however, cannot justify more than a presumptive opinion. But, if hydrochloric, acetic, or nitric acid be indicated in the subject of analysis, or an acid sulphate, the whole process is vitiated and it is scarcely possible to arrive at any trustworthy conclusion.

"(b) *When the mixture is neutral*, sulphuric acid may be detected in it by the first steps of the preceding process; but the inference, that it once existed free can only be drawn when the subject of examination is not in a state of decay, when the quantity of sulphate of baryta obtained is considerable, when the administration of an antidote is proved, and when the ashes after incineration contain the antacid base which is said to have been administered. Even then the inference is only presumptive."

We have not time to consider the many minor difficulties which stand in the way of our adopting the process just mentioned; but I may perhaps inform you of one great, and, I think, insurmountable objection to it, namely, that the stomach is almost sure to contain a free acid—a circumstance which will, as Dr. Christison admits, vitiate the whole process, and destroy even the *presumptive* evidence which might otherwise have been deduced from it; for, as all chemists are aware, a free acid is commonly present as a natural constituent of the gastric juice; and, besides this, an acid will most assuredly be liberated by the reaction of the oil of vitriol upon the muriates, acetates, and lactates, which are so constantly present in the fluid contents of the stomach and alimentary canal.

As to the method recommended by Mr. Taylor, namely, that we should make a quantitative determination of the sulphuric acid contained in two equal portions of the suspected liquor, one of which had been previously dried, I have already pointed out a few objections; and, notwithstanding that I cannot advise you to adopt this process, yet I think it hardly deserves to be considered as an operose method, that is scarcely applicable to ordinary medico-legal investigations (Christison).

(b) *Detection of the Acid in the Tissues of the Body.*—We have already seen, that sulphuric acid combines most intimately with the protein elements of the tissues, and forms compounds from which the acid cannot be removed by simple washing. Wherever, therefore, you recognise the presence of that kind of corroded epithelium, which is due to the formation of sulphate of albumen, you may be certain that you can, with a little management, obtain ample proof of the presence of sulphuric acid. And, judging from the results of a great number of experiments which I have made with this compound, I am led to think, that the best method of detecting the acid therein is the following:—Take the stomach, or the lining membrane of the œsophagus, or the brown eschar which you may, perhaps, find upon the lips, or other parts of the body; wash it, wipe it dry, and weigh it. Then dissolve it in a liquid, consisting of one part of pure nitric acid, two parts of muriatic acid, and two of water: when the solution is complete you are to filter the liquor and precipitate the sulphuric acid contained in it by means of a soluble salt of baryta. Collect this precipitate, dry it, ignite it, and weigh it. All the sulphate of baryta so obtained, which exceeds 5-10ths, or half a grain per cent. of the wet material used, may be regarded as indicating an equivalent amount of sulphuric acid which was combined with the albumen; and, therefore, the amount of sulphuric acid which had been brought into contact with the tissue in a free and corrosive state. In this calculation I have given considerable latitude to the range of sulphur normally contained in the tissues of the human body; for, in the course of my investigations, I have never obtained by this mode of manipulation more than 0·45 per cent. of sulphate of baryta from the substance of the wet tissues. In fact, the results of my experiments on the amount of sulphuric acid yielded by albumen, sulphate of albumen, the tissue of the stomach, &c., may be thus represented:—

Dry albumen yielded, on the average, 4·0 per cent. of sulphuric acid.

Dry sulphate of albumen yielded from 6 to 10 per cent.

The dry tissue of the healthy human stomach yielded, on the average, 0·6 per cent.

The tissue of a stomach which had been dipped into an acid of sp. gr. 1390, then well washed and dried, yielded 3·5 per cent.

The tissue which had been dipped into an acid of sp. gr. 1616, then well washed and dried, yielded 5·1 per cent.

The tissue which had been dipped into an acid of sp. gr. 1840, then well washed and dried, yielded 8·4 per cent.

The wet tissue of the healthy, first washed and then wiped as dry as possible, yielded 0·13 per cent.

Portions of the wet tissues of the stomach, which had been dipped in acids of varying strengths, then well washed and wiped as dry as possible, yielded from 0·9 to 2·1 per cent.

You may remark, therefore, that when the tissues of the body have been acted upon by sulphuric acid, they are converted into compounds which are insoluble in water, and which yield, upon analysis, a proportion of sulphuric acid, which is considerably greater than that furnished by the normal tissues. You may notice, moreover, that the quantity of sulphuric acid procurable from the dry tissues is about four times as great as that from the wet ones.

I have brought these facts before you because they illustrate, in a very significant manner, the value of a process which might be considered by some authorities as operose, and therefore inapplicable to the purposes of the Medical jurist. Let me, however, here remark, that no man is justified in condemning any process or method of analysis, merely because it involves a little trouble and tact; for in your medico-legal pursuits you will have many embarrassments and responsibilities to contend with, and you will not overcome them unless you take trouble and use tact: in fact, no man is fitted for the duties of a toxicologist, or warranted in undertaking, even the simplest analysis of a poisonous substance, who is not prepared to encounter greater difficulties than any here mentioned. I have long been convinced in my own mind that one of the great barriers to the advance of toxicology as a certain science, one of the great stumbling-blocks to the members of our own Profession, when they are forced into the paths of medical jurisprudence, one of the great elements for contention, doubt, and cross-examination with the forensic advocate; and, I might also add, one of the great inducements to the commission of crime, is a want of precision in our own conduct, and a disregard of philosophical rules by those who are our leaders in such matters; for, unfortunately, the writings of some of our English toxicologists are based upon anything but sound scientific principles; in proof of which I will fearlessly say, that the sciences of Physiology, Pathology, and Chemistry, the great foundations of Toxicology and Legal-medicine, are all more or less misused, and often fearfully misunderstood by them. But to proceed with our subject, other methods have been proposed by chemists for the detection of sulphuric acid in the tissues of the animal body: thus Orfila and Barruel, finding that sulphuric acid could not be washed out of the tissues of the stomach, have recommended that the organ should be subjected to dry distillation at a read heat, by which means the combined acid is liberated and decomposed. The resulting sulphurous acid is to be received into a solution of ammonia, then converted into sulphuric acid by the aid of nitro-muriatic acid, and finally tested as such by means of a soluble salt of baryta. MM. Devergie and Tauflieb, however, on resorting to this process in one of their very important cases, found that a large portion of the sulphurous acid escaped absorption by the ammonia, and was lost during the operation; they, therefore, suggested that the sulphurous acid should be received into a solution of iodic acid and starch, the former of which would yield its oxygen to the gas, and so form sulphuric acid, while the liberated iodine would re-act upon the farina, and convert it into a deep blue compound. Mr. Taylor has raised some objections to the process, upon the grounds that iodic acid is easily decomposed by numerous other deoxydising substances, as for example, by sulphuretted hydrogen, morphia, gallic acid, the sulphites, sulphocyanides, cyanides, sulphurets, saliva, and even by the tissues of the stomach itself. I do not find, however, that all the objections raised upon these grounds apply with equal force; for, in the first place, the vapours from morphia and gallic acid do not affect iodic acid when these substances are subjected to dry distillation, and, in the second place, we are not likely to have sulphurets, sulphites, or cyanides in the dried tissue of a human stomach. It is far different, however, with the fallacies which result from the operation of animal matter itself; for these are formidable objections, and you may convince yourselves of this fact by taking a few grains of dried blood, albumen, or even a small piece of the stomach itself, and introducing it into a small test-tube. On applying heat to the substance, and receiving the empyreumatic vapours upon a piece of paper moistened with a solution of starch and iodic acid, you will notice that they make the paper blue, as if a compound of sulphuric acid had been present, when, after all, the effect is due to the sulphur which is normally contained in these animal substances. Such facts as these have led Mr. Taylor to conclude, "that when sulphuric acid cannot be detected in the contents of the stomach in a free state, the chemical investigation must be considered at an end," and he even passes a severe censure on the proposition made by Orfila, who, in adverting to the difficulties which surround this subject, says that they may be removed by distilling to dryness equal weights of normal stomach and intestines, and comparing the average results with those obtained from the dry distillation of the suspected stomach; upon which Mr. Taylor remarks, that "this appears to be the refinement of medico-legal chemistry. Evidence which was based upon experiments of this kind would not be received in an English court of law; for it would be impossible to estimate the exact amount of normal sulphur in the human stomach, or its contents." I take it, however, that this observation has resulted more from imperfect theory than from actual experiment; for, as you have already seen, it is not impossible to determine the exact amount of normal sulphur in the tissues of the human body; and it is to such refinements of medico-legal chemistry that we may expect to see the science of Toxicology based upon a firmer footing, and the evidence of Medical witnesses received with more respect, and valued at a higher price; for why should not the efforts of the chemist be as refined in matters of this description as they have been for a long time past in matters connected with mineralogy, and as they are now rapidly becoming in those of physiology. I consider, gentlemen, that such remarks from our leading toxicologists are to be regarded, not merely as unmerited slurs upon the science of Chemistry, but as powerful inducements to cultivate this particular branch of inquiry with more precision and earnestness.

In our next lecture, gentlemen, we will consider the mode in which sulphuric acid is to be detected in the fluids and secretions of the body, and upon the cloths where the acid has fallen. I shall also pass on to consider the impurities of oil of vitriol, the rectification of this acid, and some of the fraudulent uses of it.

LECTURES
ON THE
PROCESSES OF REPAIR AND REPRODUCTION AFTER INJURIES.

DELIVERED AT THE

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

By JAMES PAGET, F.R.C.S.

Professor of Anatomy and Surgery to the College.

[Reported for the "Medical Times."]

LECTURE V.

Repair of Fractures.—Necessity of studying the process in the human subject; errors resulting from its study in animals.—Various modes of development of the new-formed bone: their relation to the natural development of bone from cartilage and from fibrous tissue.—General description of the process for the repair of simple fractures.—Modifications of the process in compound fractures, and in certain parts of the skeleton.—Imperfect union of fractures.

Mr. President and Gentlemen,—It is not necessary that I should enter into any detailed account of pus, but I may point out the relation of it to the process of healing by granulations. Its existence is not necessarily accompanied by a growth of granulations; and there are some cases in which these are formed independently; thus we find bones covered, after a few weeks, with their ordinary appearance without suppuration.

It would be an interesting fact if it were found that the granulations that do not suppurate are those which are formed of nucleated blastema; they are so in some cases, I know; but it is not proved of all. However, the common instances of suppurating granulations are those that are formed of nucleated cells; and with these pus may be formed, whether on an open surface, or on the walls of an abscess, or on the walls of an inflamed serous cavity, when, as in empyema, the lymph acquires a granulated surface. To illustrate the relations between pus and granulations, at least, so far as their component cells are concerned, this diagram may serve, which was copied from sketches that I made, at the same time, of some granulation-cells from the walls of a sinus, and some pus-cells from a healthily granulating wound. I chose these sources purposely, that I might be able to compare ill-developed granulation-cells with well-constructed pus-cells; and a comparison of them shows, that, whether as seen without addition, or as changed by the action of water and acetic acid, they are not to be distinguished from one another. Had I not seen the vessels in the tissue that these granulation-cells formed, I might, in the first examination, have almost thought I was deceived in thinking they were not pus-cells. Six varieties of the appearances of the cells from each source are here shown, and they severally exactly correspond. Other varieties of form might have been drawn from both sources; but these may suffice to show the apparent identity of structure between well-formed pus-cells and the ill-developed or degenerate granulation-cells, such as are found in the walls of sinuses and the like half-morbid structures. I do not mean to say generally that granulation-cells and pus-cells cannot be distinguished; for between well-formed granulation-cells, such as are found in healing wounds, and any particles that can be found in pus, certain distinctions are almost always manifest. The pus-cells are darker, more and more darkly granular, more various in size, and more various, not in shape, but in apparent structure, more often containing particles like fatty molecules, more rarely showing a nucleus when neither water nor acid is added, and much more commonly showing a tripartite or ill-formed nucleus under the action of the acid: above all, not showing any molecular movement of their contained particles when they are distended with water. From this the conclusion is obvious, that the cells of pus are ill-developed or degenerate granulation cells. Some of them may be degenerate, they may have been, as granulation-cells, attached for a time to the surface of the granulation-layer, and, having been to a certain point properly developed, and having lived their time, may, in ordinary course, have been detached and shed, as epithelial cells continually are from healthy surfaces. They may be thus detached after more or less degeneration, and hence may result some of the modifications of form that they present; but some also may be ill-developed, and which, being exposed to the air, or being too remote from the supply of blood, cannot attain its due development, and, in an imperfectly developed state is soon cast off. It cannot but be that organizable matter is constantly oozing from such a surface as that of granulations; but the conditions into which it enters on that surface are such as are very likely to hinder any but the lowest and an imperfect organization.

A further confirmation of the opinion that pus-cells are ill-developed or degenerate granulation cells, is furnished in the numerous cases in which pus-cells are produced after, or together with, inflammatory exudation-cells; as in abscesses, in inflammation of serous membranes, and the like. Now, exudation-cells are not distinguishable in apparent structure from granulation-cells, and, like these, may show every gradation of form to that of the pus cell; so that, from both cases, we may conclude that the true relation which the cell in granulations or in inflammatory lymph holds to the pus cell, is that of a well-organized structure to the same structure either ill-developed or degenerate after having, up to a certain point, been duly formed.

I come now to treat of the repair of fractures, into which I shall not enter very largely; for any one at all acquainted with the volumes which have appeared on the subject, and with the merit of those who have investigated it, will feel that there is little necessity to enter very fully into it. I shall, therefore, limit myself to an explanation of only two or three points in the history. The chief points that I have chosen are,—1st, the particulars in which the process of repair of fractures, observed in the human subject, deviates from that described from experiments upon lower animals; and secondly, the nature of the reparative material previous to its ossification. On the first point, I must express my conviction that the description drawn by Dupuytren and others, from examinations of fractures in dogs, rabbits, birds, and other animals, cannot be applied without great deduction to the case of fractures in the human subject. My impression of this was first obtained while describing the large collection of fractures for the Catalogue of the Museum of the College, and I there stated, that there was scarcely a specimen in the Museum of such a provisional callus formed in the repair of a fractured human bone; in nearly every case of such fracture, the material of repair, whether cartilage or bone, is only inlaid between the broken surfaces, or between the adjacent parts of the fragments, and unites them by being fixed to both. In favourable conditions this appears to be the usual mode of repair, even though the fragments of the broken bone be very much displaced. But the formation of a provisional callus, completely encircling the broken ends and adjacent parts of the fragments, is usual in the repair of fractures of the bones of other mammalia, and of birds. A similar, but less perfect process, is also shown in the accumulations of cartilage, or bone, which are often formed about fractures of the ribs, and of some other bones in the human subject, the fragments of which have not been held steady. It is probable, therefore, that the difference between the modes in which fractures are commonly united in man and other animals respectively, depends, in part, on the movement to which the fragments are subjected in the latter,—but, probably, in part, also, on the greater readiness with which, under all circumstances, bone is formed in the animals lower than man. Since that was written, I have examined many more specimens, and find the same rule true; namely, that in the ordinary repairs of simple fractures in the human subject, the reparative material, or callus, is merely inlaid between the several fragments: it fills up the interspaces between them and the angles at which one fragment over hangs another; but it does not encircle or ensheath them, in the manner implied in the description of provisional callus; nor is it in any considerable quantity, if at all, deposited either beneath the periosteum or within the medullary tube. In birds, dogs, and other ordinary subjects of experiments, the formation of a provisional, or, as it may, perhaps, be better called, an *ensheathing* callus, is usual. It is illustrated by numerous specimens on the table; yet even in animals it is not constant. To obtain what would be called good specimens of provisional callus, the injuries must be inflicted upon young animals, and among these I cannot but suspect that particular instances have been selected for description,—those in which less callus was formed having been put aside as imperfect instances of repair, though, in truth, they may have displayed the more natural process. For fractures in the human subject, the evidence that union is accomplished by the reparative material being placed between, not within and around, the fragments—*i.e.*, as an intermediate, not an ensheathing callus—this evidence may be obtained by the examinations of such fractures even long after they are completely healed. In as many as you like to examine, you will find the new bone formed exclusively between the fragments. Whether they were in apposition, or nearly so, or wide apart, still there is no appearance of new bone being formed on the outer side of any fragment,—I mean on that side which is turned away from the other fragments. And this is the case even in those instances in which there is so much displacement of the fragments, and so much distortion, that we can hardly suppose the repair to have proceeded very quietly. Neither in any of these do you find new bone within the medullary tube. It may be objected by some to these specimens, that the fragments were once ensheathed and blocked up with callus, and that it has been since absorbed. But this is not probable, seeing that in many cases there remain, on the outer surfaces of the fragments, certain marks of their original form and slight irregularities. In one of the specimens which I present, we have traces of the healing of a long fissure, which appears now as a sunken groove, making it nearly certain that no new bone was formed over it. In another, is a detached piece of the wall of a femur turned quite round, so that its periosteal surface lies on the periosteal surface of the principal fragment; yet on the outer surface of this piece (which was the inner surface of its wall) the thin plates forming the boundary of the medullary tube are still unchanged. But if any deem these and the like characters insufficient to prove the absence of ensheathing callus, and of callus extending into the medullary tube, yet recent specimens are not open to such doubts. I add, therefore, that (with the exceptions presently to be mentioned) in all the specimens of fracture that I have been able to examine, in the human subject, within six months of the time of the injury, there has been the same absence of provisional or ensheathing callus. The specimens here present are—a radius, four weeks after the fracture; another, four or five weeks; a tibia, five weeks; a femur, six weeks; another of the same date; a third, I should think, about eight or nine weeks; a radius, of somewhat later date; a tibia, eight weeks; a fibula, eleven weeks; a tibia, twelve weeks; and a tibia, sixteen weeks after the injury. Here are, also, others of various but unknown dates, all in process of apparently natural repair. All these were cases of simple fractures, and they include (with a few exceptions presently to be mentioned) all the specimens of such recent fractures, in the human subject, as are in the museums of the College and of St. Bartholomew's Hospital. The displacements and other conditions following the injury have been manifestly various; but all agree in this, that the fragments are united by intermediately placed reparative substance, and that this, whether soft or osseous, in no case surrounds or ensheaths the fragments, or does more than just close in the medullary canal. When present in the largest quantity, it is only enough to smooth off the chief irregularities, and to fill up the interspaces and the angles or corners, between the fragments. Such, then, appears to be the natural mode in which the reparative material is deposited for the union of fractures of human bones. And, regarding

the particular position which it may in each case occupy, I do not know that it can be more exactly described, than by saying, that it is deposited where it is most wanted for the strengthening of the bone, —so that, whatever would be the weak part of the bone, if unhealed, there is the new material placed, in quantity as well as in position just adapted to the exigencies of the case, and restoring, as much as may be, the original condition and capacities of the bone.

If now it be inquired why this difference should exist in the corresponding processes in man and other animals, I believe still that it must be ascribed principally to the two causes already quoted from the catalogue—namely, the quietude in which fractures in our bones are maintained, and the naturally greater tendency to the production of new bone which animals always manifest. Even independently of surgery, in the case of fractures of the lower extremity, the human mode of progression almost compels a patient to take rest; and in fractures of the upper extremity, the circumstances of human life and society permit him to do so far more than other animals can. The whole process of repair is, therefore, more quietly conducted; and, as we may say, there is comparatively little need of the strength which the formation of provisional callus would give a broken limb. The exceptions to the rule of difference in the repair of human bones and those of animals confirm it as thus explained; for the only bones in which, in the human subject, a provisional callus is generally or naturally formed, for the repair of fractures, are the ribs. In cases of fractured ribs one may see, indeed, a very close imitation of that which is described, from experiments on animals, as the ordinary mode of union. The provisional callus is well formed under the periosteum, and encircles, like a broad ring or ferrule, both the fragments, and may almost completely ossify before their union is accomplished, or even apparently begun. Another bone, for the repair of which, but more rarely, callus is formed around the fragments, is the clavicle; and the best specimen in which I have here seen it is one in which the fracture was not detected, and the fragments were allowed to move on one another, till the patient died twelve weeks after the injury. Except in such cases as these of fractures not kept at rest, I doubt whether a natural formation of callus beneath the periosteum, or within the medullary tube of a human bone, would ever occur. In disease, the occurrence is not so rare; for, when the natural process of union fails altogether, the loose ends of the bones may be enclosed within a case formed wholly or in part of bone; or an imitation of callus may be made by a gradual morbid accumulation of bone around a fracture, even after its natural union. But I think the comparative restlessness of animals is not alone sufficient to account for all the difference in the processes. The remainder may be ascribed to their greater tendency, in all circumstances, to the formation of new bone. Not in fractures alone, but in necrosis this is shown. It is very rarely that such quantities of new bone are formed in even children, as are commonly produced after necrosis of the shafts of bones in dogs or other animals; nor is there in the human subject any such filling up of the cavities from which superficial sequestra have been separated, as the experiments of Mr. Hunter showed, after such exfoliations from the metatarsal bones of asses.

The next point on which I proposed to speak, concerned the structure of the reparative material thus deposited within the fragments. In reference to this, it seems essential that I should refer to those recent observations on the natural process of ossification, which have shown that bone is as commonly and as naturally formed through fibrous or membranous tissue as through cartilage. Dr. Robert Nesbitt appears to have been the first who described the ossification of certain bones, especially those of the vault of the skull, as being effected in membrane. His account of the difference between the ossification of the bones of the skull and that of the vertebræ, the pelvis, and the bones of the limbs, is so far accurate, that it appears strange it should not have directed subsequent inquiries much more than it did. But the distinction that he pointed out was, after his time, only occasionally insisted on; and till very recently the opinion generally accepted was, that the bones of the vault of the skull are formed by the ossification of cartilage, and that their development differs from that of the other bones only in this,—that there is no complete cartilaginous basis formed for each bone before ossification, but that cartilage is formed in the membranous coverings of the brain, just previous to the formation of the bone. Thus, in the parietal or any of these bones in process of ossification, it was held that a thin border of cartilage might be always found projecting beyond the bone; and that, at the same rate as this border ossified, so another, cartilaginous like it, would be formed in preparation for the next step of ossification; the formation of the cartilage only just keeping in advance of its ossification, till the formation of the whole bone was perfected. But, even while this opinion was gaining ground from observations in the Mammalian fœtus, doubts of its truth were arising from examinations, instituted by Von Baer, into the construction of the primordial cartilaginous skulls of fish. These inquiries were, however, little regarded, till Duges published his researches on the Osteology of the Batrachia. In these he showed that the skull of the naked, tailless, Amphibia is originally entirely cartilaginous; and that the bones of the perfect skull develope themselves in part from the cartilage of the fœtal skull, and in part on the exterior of that cartilage, in the perichondrium. Thus he gave strength to the opinion which Von Baer had entertained of the development of the skulls of fish, and directed the observations of many subsequent inquirers. Dr. Sharpey has not only fully confirmed these views, respecting the ossification of the bones of the vault of the skull, but has added this important fact, that the ossification by which the long bones increase in their circumference takes place, not in layers of cartilage successively formed beneath the periosteum, but in layers of fibrous substance; in short, that the peripheral growth of bones that are formed in the first instance by ossification of cartilage, is effected by ossification of membrane. Thus, then, it will appear that the peripheral growth and ordinary maintenance of all bones, after the ossification of their primordial, and for a time growing, cartilage is completed, is effected by the ossification of membranous or fibrous tissue. I would call it fibrous rather than membranous, because in some instances, as the patella and other sesamoid bones, and in the union of fractures, and the growth of some tumors, a mass of tissue, rather than a membrane, ossifies. Thus much of preface seemed necessary to explain the cases in which the material for the repair of fractures is transformed into bone through the development, not of cartilage, but of fibrous tissue. What I have just said of the later growths of bones being accomplished by ossification of fibrous tissue, not of cartilage, might lead one to expect that all ossification for the repair of fractures, after the termination of the usual period for ossification through cartilage, would be accomplished through the formation of a fibrous substance. But it is not so: rather, in the examination of many specimens, one finds the new bone formed in some through fibrous tissue, in some through cartilage, in some through fibro-cartilage, or a mixture of the two; and, in yet further deviation from any single rule of development, the bone may be formed through either cartilage or fibrous tissue, in either a rudimental or a perfect state. The changes that ensue directly after a simple fracture are in accordance with what I have already described in relation to the general repair of injuries. A period of rest follows the injury; and for a week or ten days no change may be observed, at least in fractures in the adult long bones; and here, at once, is a point of contrast with the consequences of fracture in the lower animals; for the specimens, (exhibited,) showing the consequences of fracture of the tibia in rabbits six, ten, and fourteen days after the injury, prove that a perfect cartilaginous callus is in them formed in a shorter time than would elapse before the commencement of any distinct reparative process in man. For contrast, one may notice the unchanged state of the periosteum round the broken human bones; for this, in ordinary cases, is neither raised by deposit beneath it, nor in any way altered—except, it may be, by slight thickening—during the whole healing of the fracture. The first new material produced after simple fracture consists of the lymph and serum, which are effused in consequence of the inflammation that the violence of the injury excites. But these, as in the repair of other subcutaneous injuries, are presently overwhelmed and enclosed (as the effused blood also is) by the more proper reparative material. How this is placed I have already said. In a plan, wherein one cannot overlook the evidences of particular design and of appropriate purpose, it is inlaid between the fragments, wherever, when the limb comes to be used, the most new bone will be necessary for its strength. Thus, it may take the various forms of groins and buttresses, arches, beams, or bridges, according to the mode and degree of displacement of the fragments. Thus placed, its development proceeds. I cannot tell the conditions which will determine, in each case, the route of development towards bone that the new material will take; nor whether the differences that may be observed are to be ascribed to the seat or nature of the injury, or to the condition of the patient. All these things have yet to be determined; and I believe that years of patient and well-directed investigation will be requisite for them. I can do little more than point out the modes in which the ossification may be accomplished.

First, it may be accomplished through perfect fibrous tissue. Thus I found it in a case of fracture of the lower part of the femur, and in a fracture of the radius; thus, too, I think, whatever new bone formed after fractures of the skull is developed; and thus, too, one may find, in the neighbourhood of fractures and other injuries of bone, ossifications of inter-osseous fibrous membranes, and of the tissue of the periosteum, or just external to it.

But, secondly, the bone may be formed by ossification of the fibrous tissue in a rudimental state. And this rudimental state may be that of either nucleated cells, or nucleated blastema. Through nucleated cells, as the embryo forms of fibrous tissue, bone is formed when granulations or inflammatory effusions ossify. The process may be often seen in the union of compound fractures, or of simple ones, when much inflammation has been excited; but, best of all, the ossification of nucleated cells, in granulations, may be observed when bone is formed in the mushroom-shaped mass of granulations that is protruded through the medullary canal of a bone sawn across in an amputation.

The ossification of nucleated blastema, such as I have described as a rudimental form of fibrous tissue, may also be seen in simple fractures; and my impression is, that it is the ordinary mode of ossification in simple fractures of long bones that unite well and quickly. In such a case, in a fracture of the tibia, I found, in long-continued examinations, that the bone is formed without any intermediate state of cartilage; a finely and very closely granular osseous deposit taking place in the blastema, and gradually accumulating so as to form the delicate yet dense lamellæ of fine cancellous tissue. The nuclei of the blastema appeared to be enclosed in the new-forming bone, and I thought I could trace that they became the bone-corpuscles; but I could not be sure of this, nor, indeed, could I, in either this or any other examination, satisfy myself that the origin of these corpuscles is in any structures previously existing in the soft or unossified tissue. Their first appearance in the forming new bone is too obscure, I think, to warrant any positive opinion; neither could I trace how the nucleated blastema, or other structure which is included within the new cancelli, is transformed into the latter and more perfect medulla; only, one sees fatty matter gradually accumulating. Such are instances of the ossifications, for the repair of fractures, that may be accomplished through fibrous tissue; and all these are possible without the intervention of the smallest portion of cartilage. But

perfect cartilage, with its characteristic homogeneous intercellular substance, and its well formed cells, and all the characters of the purest cartilage, may be produced. In youths and adults I have found only varieties of fibrous cartilage; but these have presented numerous gradations of structure, from the fibrous towards the perfect cartilaginous structure. In different specimens, or sometimes even in different parts of the same, the reparative material may display—in one, fibrous tissue, with a few imbedded corpuscles, like the large nearly round nuclei of cartilage cells; in another, a less appearance of fibrous structure, with more abundant nucleated cells, having all the characters of true cartilage cells; and in a third, a yet more nearly perfect cartilage. Through any of these structures, and apparently by the same method through all, the reparative new bone may be formed. Its corpuscles, being first of simple round or oval shape, and then becoming jagged at their edges, subsequently acquire their canals, which appear to be gradually hollowed out in the preformed bone as minute channels communicating with one or more of the corpuscles. The laminated canals for blood-vessels, I think, are later formed. At first, all the new bone forms a minutely cancellous structure, much like that of the fœtal bones in their first construction; but this gradually assimilates itself to the structure of the bones that it repairs, while its outer portions assume a compact laminated structure, and its inner or central portions acquire wider cancellous spaces and a more perfect medulla. But, in regard to many of these later changes in the bonds of union of fractures, there are so many varieties in adaptation to the peculiarities of the cases, that no general account of them can be rendered. Only, specimens and drawings show the most striking evidences of design in the adaptation of the reparative process to the particular exigencies of each case; so that it might be said, with complete truth, of every instance, that whatever is necessary, whatever may best repair the damage, that is done.

ORIGINAL CONTRIBUTIONS.

RETROVERSION OF THE UTERUS AS A CAUSE OF STERILITY.

By EDWARD RIGBY, M.D., &c.; Senior Physician to the General Lying-in Hospital; Examiner in Midwifery in the University of London.

Mrs. P., aged 23; married three years; never pregnant.

March 4, 1846.—Blanched, anæmic, exhausted, pulse feeble, pupils dilated, vertex headache, constant retching, much gastric derangement. Has passed considerable quantities of dark brown matter from the bowels, and had vomited blood also from the stomach. Complains of much pain at the lower part of sacrum. Has been suffering from menorrhagia ever since her marriage, but latterly the catamenia have become extremely scanty; they ought to have appeared five or six days ago, instead of which the above symptoms of hæmorrhage from bowels came on.

Examination par Vaginam.—Os uteri forwards; cervix passing backwards, tense, swollen, but not very tender; a globular mass can be felt behind, into which the uterine sound passes, taking a course backwards and downwards, showing it to be the fundus uteri, which is retroverted. I replaced it before I withdrew the sound.

℞ Hydrarg. chloridi, gr. ij.; morphiæ hydrochlor., gr. ¼; h. s. s. et repet. 6 tis. horas ad tertiam vicem.

℞ Acidi hydrocyanici (Scheele) ♏ xx.; acidi hydrochlor. dil., acidi nitrici dil. aa. ʒii.; syrupi aurantii, ℥i.; aquæ cinnamoni, ℥i. M. ft mistura cujus sumat cochl. med. j. ter die ex aqua.

℞ Magnes. sulph. ʒi.; acidi sulph. dil. ♏ viii.; Syrupi rhœados ʒss.; aquæ menth. pip. ℥i. M. ft. haust. o. m. s.

March 31.—Has been much better, and has regained her strength. She has had no hæmorrhage from the bowels since, and the catamenial period has just passed without any appearance of the menses; is going into the country.

The menorrhagia, which had so seriously reduced her, might have been an effect of the uterine displacement, as it is well known to be an occasional consequence of retroversion; but the displacement does not appear to have existed in any severe degree until latterly, and had probably been aggravated by the debility and loss of tone produced by the hæmorrhage.

A considerable amount of gastric and intestinal derangement also existed, but how long this had been the case, and whether it was habitual, I had not the means of ascertaining. In many of these cases it is extremely difficult to decide which is cause and which is effect, for what at one period has been an effect at another re-acts as a cause. I had not an opportunity of seeing my patient again, nor have I heard from her since, which I wished to have done, as, with improving health, the non-appearance of the catamenia, gave rise to the suspicion that pregnancy might possibly have taken place.

Mrs. W., aged 29; married four years; never pregnant.

Nov. 25, 1847.—Pale and delicate; complains of a sensation in the lower part of the abdomen of a "solid lump," as she calls it, which, at times, is forced low down into the pelvis, producing great pain both behind and in front. Much leuchorrœa; the bowels are confined, and she feels an obstruction in the rectum when she tries to evacuate them, the fæces being flattened; her general health tolerably good.

Has always suffered from dysmenorrhœa, the pain coming on for one, two, or even three weeks, before the appearance of the discharge, which, although scanty, greatly relieves her. Whilst the pain lasts, she feels very sick.

About nine years ago she had an attack of menorrhagia, which lasted for two months, and another at the age of fourteen; but she did not suffer the very severe pain until she was eighteen.

Examination per Vaginam.—Fundus retroverted and much swollen; uterine sound passes at least three inches; the posterior wall is thickened.

Pil. hydrarg.; extr. coloc. co. aa gr. v., o. n.

Let her wash out the bowels with a large enema; let her take a teaspoonful of bran in some warm milk at night, and use the prone position as much as possible.

I am unable to give any further details of this patient, as I have not seen her since; but the case presents several points which are interesting.

I should presume that this has been a case of retroversion from an early period of life; at any rate, coeval with the first attack of menorrhagia, which she had at fourteen; that she was probably disposed to it by constipation, but that the displacement was not produced until the uterus had become more bulky and heavy by incipient menstruation. My reasons for coming to this conclusion are, that she had suffered more or less from dysmenorrhœa for many years; that it was of the obstructive species, as shown by the lengthened attacks of pain continuing for some weeks before each menstrual period, and by the immediate relief which she experienced on the appearance of the discharge. Examination with the uterine sound showed that the canal and the cervix were not contracted, but that the fundus having been forced downwards and backwards, the canal at its upper and narrowest part had been considerably curved, and thus the exit of menstrual secretion obstructed until sufficient accumulation in the uterine cavity, and consequent uterine action, had occurred to expel it.

The distance to which the uterine sound passed, viz., three inches, showed that the cavity was enlarged, a result probably in the first instance of constant distension, and latterly from increase of fibrous tissue, as indicated by the thickened condition of the posterior wall. The sense of pain and obstruction during the passage of fæces, and their flattened appearance, showed that the fundus pressed firmly against the rectum.

The two attacks of menorrhagia were probably owing to ovarian irritation connected with the displacement of the uterus, and also to the obstruction which this produced to the returning circulation.

As in the former case, so here, effect after awhile re-acted as cause. Constipation, probably, in the first instance, produced the retroversion, and afterwards the pressure of the fundus upon the rectum produced constipation.

The only treatment required was to diminish, as far as possible, the pressure of the intestines upon the uterus, and give the patient such a position as should induce the large and heavy uterus to incline forwards by its own weight. Besides the simple pill which I prescribed, I recommended her to take some bran in milk. This, like brown bread, acts very effectively on habitually costive bowels, not merely as a mechanical irritant; but also, in great measure, by preventing the feculent mass from becoming coherent, and consequently indurated. The large enema is also a most effective means in these cases, and frequently succeeds in dislodging accumulations of long standing; for a remarkable instance of which I may refer to Mrs. P.'s case in this Journal, Jan. 1845. The prone position was well adapted for this case; but, how far she persevered in the use of it I am unable to say.

Mrs. F., aged 28; married six years; never pregnant.

March 1, 1847, Brunette.—Complains of a constant sensation of weight in the pelvis, constipation, gastric derangement, and much languor; continual headache of a neuralgic character; hæmorrhoidal congestion; turbid urine; considerable irritability of bladder, and occasional severe strangury; leucorrhœa. Suffered severely from dysmenorrhœa. The pain commences slightly at the half-way period; it gradually increases as the time approaches, and is at its height two or three hours after the discharge has made its appearance. The discharge is very dark, with clots and exudations. The acute pain is across the symphisis pubis, extending to the left groin and thigh. The neuralgic headache generally follows the cessation of this pain. Has noticed these various symptoms from five to six years, during which she has gradually lost flesh. She remarks, that the irritability of the bladder is worse at the commencement of a catamenial period, and that she feels relieved by lying on her stomach.

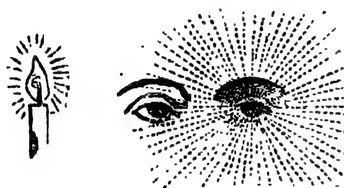
Examination per Vaginam.—Os externum very small. Fundus uteri can be felt in the recto-vaginal pouch. It is very tender to the touch. The uterine sound passes readily into it, and I returned it to its natural position.

℞. Extr. aloes aquosi, ℈ii.; extr. hyoscyami, ℈iss.: mastiches, gr. xij.; misce, ft. pil. xx.; sumat j. ij. h. s.

℞. Magnesiæ carb., gr. xv.; mannæ, ʒiss.; sp. myrist., ʒss; aquæ carui, ℥iss.; mist. ft. haust. primo mane sumendus.

The above case and the one preceding it present many features in common. Two young women, married some years, without the slightest indication of conception having taken place, both suffering from dysmenorrhœa more or less of an obstructive character, which, as well as the sterility, in great measure depended on the retroverted state of the uterus. In this last case, the pressure of the displaced organ appears to have been more constant, and anteriorly than posteriorly, considerable irritability of the bladder being produced, which was occasionally aggravated into severe strangury. There were also more decided marks of ovarian suffering, as shown by the pain in the left groin extending to the thigh, and by the clots and exudations which were mixed with the catamenia; the disposition, also, to nervous or spasmodic pain coming on after the discharge had commenced, and the metastatic headache of a neuralgic character, which followed the cessation of the dysmenorrhœal pain, were probably connected with the ovarian affection. The relief, which the patient had found she could obtain by assuming the prone position, was an interesting fact to me at the time, because I was only coming to the conviction, that it might prove a valuable means for throwing the fundus forward in retroversion, where it was undesirable to use the supporter.

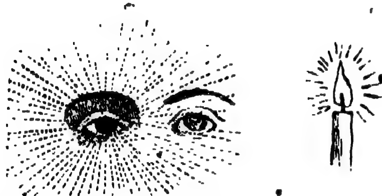
REMARKS ON AN OPTICAL EXPERIMENT,



ADAPTED AS A MEANS OF ASCERTAINING THE RELATIVE POWERS OF THE EYE, AND INDICATING THE FIRST ONSET OF MORBID CHANGES INTERFERING WITH VISION.

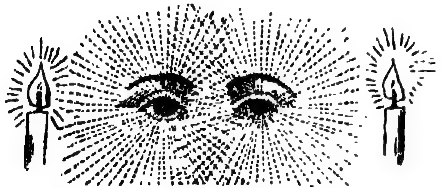
By J. D. MACDONALD, Esq., R.N.; M.R.C.S.

It is a fact but little observed, that when a stratum of dust is laid upon the surface of a mirror, each particle and its reflection so lie, one with respect to the other, that a line drawn through them both, will be, in every case, as the radius of a circle, whose centre is in the pupil of one of the observer's eyes as seen in the glass; so that an appearance of rays is thus produced, seeming to emanate from that point. The matter in itself is trivial, but, from what follows, it will be found to afford a delicate test for discovering the relative strength or visual capacity of one eye, compared with the other hitherto a desideratum in ophthalmic surgery.



If the right eye be illuminated by a candle while the left remains in shadow, the experimenter will perceive, by looking into a mirror, prepared as above, that the irradiation proceeds from the pupil of the shaded eye; and this without reference to its position.

1.



Placing the light on the opposite side (the left), the physical circumstances are altered, and the appearance is just the reverse of the former case.

2.

But, should two candles be employed, one on either side of the observer's head, the lines formed by the dust particles, and their reflections, will either seem to irradiate from both eyes, as centres, or to spread from each side mutually across the opposite eye.

3.

In explanation of these facts the writer finds, that when any circumstance incapacitates either eye from discharging its functions perfectly, (as the light in the first and second experiments cited,) the unaffected organ appears to have dominion, and this is manifested by the radiation of the particles seeming to take place from its pupil in the mirror, and overpowering those of the other eye. In consequence of the sympathy existing between the optic nerve and iris, when a strong light falls upon the latter, the pupil diminishes in size, so as to regulate the amount of light impinging on the nerve, according to its sensibility. When one eye is thus influenced, its powers are lessened considerably, for, while it is directed to the image in the glass, the iris cannot admit a sufficient amount of light to impinge upon the retina, from that quarter, having a much stronger stimulus in active operation to contend with from another. This state of things is quite reversed in a shaded eye, because the iris is free from the action of a powerful light, and has only to discharge its office in allowing the ingress of as many rays from the dust particles of their reflections as the delicacy of the optic nerve can bear, which fully accounts for the strength of the impression overpowering that of the weakened eye.

When two candles are employed, as in the third experiment, both eyes are equally influenced, receiving a similar distribution of light, and are, consequently, alike fitted (*cæteris paribus*) for the performance of their respective functions, so that the lines necessarily appear to irradiate from both eyes.

Now, the practical application of the experiments alluded to, (if properly conducted,) is this, that the least inequality of the powers of one eye when contrasted with those of the other, is instantly discovered, and the earliest onset of cataract, amaurosis, &c., is at once detected; for, if both eyes are similarly situated before a light which falls equally upon each, the patient will himself discover where the defect lies, independent of any other proof, agreeably to the explanations above given.

A very close relationship exists between the co-ordination of the muscular movements of the eye-balls and the function of adaptation to distance, and also an intimate connexion between this latter and the condition of the retina. Thus, if the retina of one eye be in any state of debility, the adaptive changes do not take place equally in both eyes, and, as a necessary result, the co-ordination of the muscular actions which so wonderfully effects the concentaneous movements of the eye-balls is disarranged, and strabismus (or squinting) is, under such circumstances, satisfactorily accounted for. If, then, in consequence of debility of one of the retinæ, whether from disease (as is usually the case), or from whatever cause, there is a tendency to squint, the eye so disposed may be instantly detected by the foregoing experiment, in which it also assumes its wonted position. This test has been successfully tried by the writer in the case of an individual who had been subject to an occasional strabismus, frequently resulting from long concentration of the eyes on one plane, as in reading. There was a loss of co-ordination both in the muscular movement of the globes and the power of adaptation to distance, and, in short, a want of balance in the tone of both organs. On looking into the mirror, as before explained, with an evenly adjusted amount of light on each eye, he observed the rays emerging from the left eye to cross and obliterate those from the right, which indicated to his own feelings and convictions, that the latter was the organ affected.

The advantage of such a test as the present to the ophthalmic surgeon, must be obvious, when we consider that the sound eye has been frequently operated on in cases of strabismus, in consequence of incompetent diagnosis.

56, Berners-street.

MEDICAL SCHOOLS AND UNIVERSITY TOWNS OF GERMANY.

By Dr. BUSHNAN.

(Continued from page 118.)

WURZBURG.

Of the Medical Schools of Bavaria, the first is that of Wurzburg. It was formerly equal to Prague, and still deserves the next pre-eminence, not only on account of its antiquity, and the high character uniformly sustained by its Professors, but also as regards the general facilities it now affords to students.

Wurzburg was of old the metropolis of the Franconian Bishops, who, as princes of the empire, and most pugnacious members of the Church Militant, formerly exercised great influence in Germany. For more than a thousand years it was their fortress and their residence,—a fact which will enable the visiter to account for the number of churches, which cannot fail to strike his eye. As may be expected, the Romanist religion predominates, and, perhaps, in no other town of His Most Royal Majesty of Bavaria's dominions does proselytism, prejudice, and bigotry, exercise so decided and palpable an influence, or the priest so extended and subtle a sway, as in the good old University town of Wurzburg. It is beautifully situated on the Maine, and contains a population of about 27,000. The [illegible] view of it is obtained from the Marienberg or C[illegible]el, on the left bank, from which point the town presents an imposing appearance. The picturesque and prettily-wooded hill, producing the grape, from which is made the celebrated Stein wine, forms a lovely background, and the meanderings of the silvery Maine impart to the landscape an additional attraction. The Citadel itself is said to occupy the site of one of the fifty Roman castles built by Drusus in Germany. Its present remains consist of a donjon and other usual indications of a feudal edifice, not unmixed, however, with several characteristic features of modern innovation, in order to adapt it to the objects or convenience of subsequent possessors. The whole is surrounded by bastions, &c., on the principles of modern fortification, and each portion of these bears the arms or effigy of the warlike Churchman under whose rule it was constructed.

The University was founded in 1403, and was repaired and restored by Bishop Julius, the founder of the Hospital, in 1582. It is more frequented by foreigners (a) than any other of the Bavarian schools. The average number of students for the last three years has been about 480, of whom from 160 to 180 are Medical.

Wurzburg has possessed many celebrated Professors, among whom we need only refer the reader to Siebold, Jarger, Schoenlein, Textor, and Outrepont; and every department of Medical science is well and ably filled. Before I speak further, however, about the Professors, let me describe more particularly the Institution to which they are attached—I mean the Julius Spital. It is an edifice of palatial extent, originally erected by Bishop Julius, of Maspelbrunn, but repaired and restored, after an accident by fire, in 1701. It forms a magnificent asylum for the aged, the sick, and the poor, and is, at the same time, the chief School of Medicine. It is richly endowed, possessing a capital of at least 6,000,000 florins—about 500,000*l.* sterling; and amongst the estates belonging to it are those producing the finest sorts of wine for which the neighbourhood is celebrated. The Hospital forms a quadrangle, containing 30 wards and 400 beds. The arrangements throughout are most praiseworthy, and the whole establishment is remarkable for its extreme cleanliness, a recommendation which German hospitals do not always so eminently possess. It fails, indeed, in no arrangement that can tend to promote either its convenience or efficiency, for it has its own mill and bakehouse, ample cellars and storehouses, dispensary, dissecting-rooms, laboratory, botanical garden, library, and church; the latter a very neat little building, supplied by two clergymen, who reside in the Hospital. The number of patients during the last year was upwards of four thousand. The division and appropriation of the building is as follows:—

The ground-floor comprises the rooms for ophthalmic patients, the auditorium, and dwellings for the various officers of the Institution, a spacious, well lighted, operating apartment, and wards for cutaneous and syphilitic disorders. The medical clinic is under the charge of Professor Marcus, a pupil of Schoenlein; the hours of attendance are from eight to nine, and the fee only 12 florins, 1*l.* sterling, for the semester. (b) The surgical clinic, including

(a) By the term foreigner, whensoever it be used throughout these papers, is implied, not only natives of other lands, but *Germans* also, born out of that particular section of their country in which the University under consideration is situated.

(b) A semester, or session, as calculated in this country, means a period of six months. They are distinguished as summer and winter semesters.

the cutaneous and syphilitic diseases, is directed by Professor Textor, a skilful surgeon, of acknowledged reputation. This costs, also, 12 florins for the session.

In one of the wings of the Hospital is the Lunatic Asylum. All convalescents are placed together in commodious apartments; those, however, whose cases are more severe, are imprisoned—we can find no better term for it—*in single and narrow cages!*

An assistant Physician occupies an apartment attached to the Hospital ward, with whose superintendence he is charged. Here he gives private lectures, on chosen subjects, at a charge to each pupil of from 10 to 15 florins.

The dissecting-house is attached to the principal building, and contains a theatre and an excellent pathological collection. A series of smaller rooms serve for private courses, and for the examination of all persons who die in the Hospital. The whole building is well supplied with water, and great attention paid to cleanliness.

It has been found desirable to appropriate to more general purposes the rooms now used for dissections and anatomical lectures; and an extensive plot of ground, immediately behind the Hospital, has lately been purchased, for the erection of a still more spacious and convenient building for anatomical purposes only.

The anatomical students are under the care and tuition of Professors Munz and Siebold. The terms, 20 to 24 florins, are high for this country.

The courses in comparative anatomy, as well as physiology, are held by Koellicker, who was called from Zurich to re-organize and direct the physiological Institute.

Immediately opposite the dissecting-house is the botanic garden, in which is also a building containing a lecture-room, the pharmaceutical museum, and the laboratory. Professor Rumpf is the director of the latter, and Professor Leiblain has the superintendence of the garden.

The lectures on organic chemistry are delivered by Professor Scherer, in this department, perhaps, but little inferior to his teacher Liebeg. The study of pathological anatomy has sustained a great loss by the recent death of Professor Mohr.

Not far from the Hospital is the Maternité, containing only thirty-five beds. Its limited size is, however, a recommendation to the student, as every patient is more carefully attended, and the case scrupulously noted. The apartments are particularly clean and well ventilated, and a small, but well laid-out, garden, which runs round the building, affords the women opportunities both of air and exercise. One room contains a collection of instruments, and cases of deformed pelvis. Another is appropriated to midwifery lectures. Every pregnant woman, on entering the Maternité, is consigned to the care of a student, who enters her name and address, notes the particulars of her case, and attends her delivery. The establishment is under the direction of Professor Kiewisch-Rotterau; the course costs 12 florins.

Besides the medical, surgical, and obstetric clinic, there exists a Dispensary, where patients are attended by students, or visited at their own houses, under the superintendence of a Professor. Here the student soon learns to acquire a certain degree of self-dependence, being obliged, in the first instance, to attend the patients alone, the principal medical man only visiting them at certain periods, or when his presence is especially required by the attendant pupil, who must report every day a concise account of the patient under his charge. The director of this establishment is Professor Rinecker, and the terms for the course is twelve florins.

Lectures on the disorders of children are given by Professor Rinecker, under whose superintendence are also the Hospital, the Ehchaltenhaus (Asylum for Aged and Infirm *Married People*), the Burgher Hospital, and the Lazzaretto. The three former are appropriated to the aged and infirm poor; the latter serves for the reception of syphilitic and cutaneous diseases.

The zoological, geological, and Mineralogical Museums, and the Library, are in the University.

In some of the Medical Schools of Germany, the degree M.D. is easily obtained by Englishmen, and, indeed, by foreigners of any country. (a)

In Wurzburg, the degree can be obtained by foreigners only after examination. The expense amounts to about 300 florins, or twenty-five pounds sterling.

There is no doubt that student life in Wurzburg is pleasant enough: there is no want of balls, concerts, and general society during the winter, nor of the usual out-door enjoyments of the country, together with lovely walks, pleasant rides, and boating into the bargain, if desired. It is, moreover, not difficult to become acquainted with the inhabitants, if the stranger conduct himself quietly and respectably. If fond of music, twice a-week, the classical works of Brethoven, Mozart, Haydn, Spohr, Mendelsshon, and other great masters, are admirably executed by Doctor Freolich's scholars. A well furnished room costs from six to eight florins per month. Dinner is to be had in the various hotels or private eating-houses, at from eighteen to thirty kreutzers. There are five University clubs, but an Englishman need not attach himself to either of these, unless he be so disposed.

Although French is very much spoken in Wurzburg, it is, nevertheless, highly desirable that any one going thither to reside, should possess some knowledge of German, which will tend greatly to promote his comfort, amusement, and means of instruction. If, then, his stay is not a happy one the fault will most certainly be with himself, for we know of few pleasanter places, nor any that afford more agreeable facilities to the medical pupil, than the venerable and beautifully-situated old town of Wurzburg.

ON SCARLATINA.

By J. W. TRIPE, M.D., M.R.C.S., and L.A.C., London.

(Continued from page 6.)

B. c. d. It has long been believed that variations in the electrical state of the air have produced epidemics, or rather have converted sporadic into epidemic diseases. For instance, it has been stated that cholera took its rise in consequence of a violent storm, which was attended with unusual electrical phenomena; or, that certain alterations (which have not been demonstrated) in the electrical condition of the air assisted in its spreading. That alterations in the activity of the electricity possess an influence on disease, there can scarcely be any doubt; and that this influence preponderates in those diseases which depend on the absorption of a morbid poison into the system, whether that poison be contagious, or infectious, or both, there can also be but little question. The great length to which this memoir has already extended, will prevent the same plan being adopted in the consideration of this division of our subject, but I hope to show that an active condition of the electricity of the atmosphere is much more favourable to life, as regards scarlet fever, than a passive condition of it. It has been remarked, in the reports of the Registrar-General, that the last quarter of the year 1847 was characterized by an unusually small number of manifestations of electricity, and it is also equally as well known that the present epidemic of the disease commenced at the same time. It will also be shown that the whole of this year has been attended with but comparatively few manifestations of electricity, especially in the latter half of the year, during which period the disease has been so rife.

But in considering the variations in this agent of disease, we must not forget that other agents have been shown to have favoured the spreading of the disease; for, in the first place, the temperature in February, March, April, and May was above the mean, especially in February, April, and May, in the two former of which it has been shown that a low temperature is unfavourable to the progress of the disease. It has also been shown, that a great degree of saturation of the air with aqueous vapour, —in other words, a high degree of the mean humidity of the atmosphere—is also unfavourable to the spreading of scarlatina, and *vice versa*; and, on examining the mean humidity of the atmosphere for this year, we find it to have been below the mean for the nine years under consideration without one exception. These facts must be born in mind when considering the influence of electrical variations:—

1848	31	14	4	193	99

In five of these nine months the electricity in the atmosphere was more active than ordinary, and in four it was unusually passive. In the five months in which the evidences of free electricity were unusually great, the mortality was unusually small in four and high in one, whilst in the four in which the free electricity in the atmosphere was unusually small, the mortality was unusually great in three, and smaller than ordinary in one. The mean of the comparative mortality for the months that presented an unusually large number of instances of free electricity, amounted to 88, and for those months which showed a small number, to 91. It therefore appears that an active state of the electricity of the air assists in restraining the progress of scarlatina during the winter quarter, and *vice versa*:—

In six of these nine months the electricity was unusually active, the comparative mortality being smaller than ordinary in four, and greater than usual in two; whilst in the three in which the electricity was unusually passive, the comparative mortality was small in one, and great in two. The mean of the comparative mortality for the months in which the electricity was active was 103, and for those months in which it was unusually passive, the mortality was 119. It seems as if the more frequent and the more powerful were the evidences of free electricity in the at-

(a) In consequence of some observations on this particular which have reached us, with regard to our former paper on Prague, we may here observe, that Prague forms altogether an exception to this. The examination for a Doctor's degree is there very severe, and it is not usual to grant that diploma to *any foreigner*. We heard of a case where an Englishman, some years ago, offered the fees, and also a thesis in proof of his qualification, when he was dryly told, that "the production of his English certificate as M.D. would be sufficient without his thesis, or any further examination." Of course, the Prague degree was never obtained!

mosphere, the less did the mortality from scarlatina increase, and the contrary. This conclusion is the same as that which has been obtained for the winter quarter.

September.					
1846	25	4	5	64	
1847	31	4	6	147	
1848	21	2	13	604	

The connexion between the frequency with which evident traces of electricity were detected by the instruments, and the mortality from scarlatina becomes much less marked in this quarter than in the preceding, as, in the five months in which the electricity was less in equilibrio than in the others, the comparative number of deaths was twice higher and three times lower than ordinary; whilst in the four in which it gave less traces than usual, the mortality was plus three times and minus once. The mean of the comparative number of deaths for the former six months was 127, and for the latter three 129. The balance of evidence is, therefore, slightly in favour of an unusually active state of the electricity of the air diminishing the number of deaths from scarlatina. There was, however, a marked exception to the rule in September, 1847, when the increase in the mortality from the disease was unusually great, whilst the equilibrium of the electricity of the atmosphere had been more frequently disturbed than in any of the other months. We may, perhaps, however, account for this by the temperature for this month being lower than usual, and the main humidity of the atmosphere being also minus the average, both of which have been shown to assist in increasing the number of deaths from scarlatina during the month of September.

1847	35	2	6	188	73
1848	21	4	20	134	85

The results obtainable by a consideration of this Table are directly opposed to those arrived at in the treating of the other months, and these months are very remarkable for the variations in the frequency with which the electricity manifested itself. If we consider the absolute mortality, we shall see that the deaths were in excess in those months in which the electricity of the atmosphere was but little manifested; and that they were in a minus in the months in which the electricity was unusually active. But the contrary of this is obtained by comparing the electricity with the comparative mortality, when we see that the electricity was active in three months, and passive in six; the comparative mortality in the three former being twice in excess, and once in a minus; and in the six latter, being twice in excess and four times in a minus. The mean of the comparative mortality for those months in which the electricity was unusually active was 119; and for those months in which it was unusually passive the mortality was 102.

Another plan, to consider the influence of electricity on the disease, may be adopted, viz., to take the absolute mortality in the month of January of each year as the unit for that year; to divide the total number by that unit, and to compare this result with the activity of the electricity. Thus, the number of deaths from the disease in January, 1846, was 73; in January, 1847, was 63; and in January, 1848, was 180; or in the following proportions: in 1846, 116; in 1847, 100; in 1848, 286. The total number of deaths in the year 1846 was 928; in 1847, 1,433; and in 1848, 4,756. The electricity existed in a free state in the atmosphere in the following proportions: in 1846, 731; 1847, 655; and in 1848, 463. If the total number of deaths in each year are divided by the number of deaths in each January, or by their equivalents, the result will be as follows:—

FOR THE METROPOLIS.

Year.	Deaths from Scarlatina.	Evidences of free Electricity.
January.		
1846	928 ÷ 116 = 8·00	
1847	1,433 ÷ 100 = 14·33	
1848	4,756 ÷ 286 = 16·60	

The greatest proportionate, as well as the greatest actual, increase in the mortality from this disease, occurred in the year in which the electrical equilibrium was least disturbed; the next greatest increase happened in the year which presented the next smallest evidences of free electricity; and the smallest increase occurred in that year in which the electricity was unusually active. Taking these years as our standard, we may say, that frequent disturbances of the electrical equilibrium are very favourable to health as regards scarlatina; whilst an inactive state of the electricity favours the assumption of the epidemic form.

B.d. The weekly and quarterly Reports of the Registrar-General afford irrefragable proof, that bad ventilation, imperfect drainage, and other imperfections which afford miasmata from decomposing animal and vegetable matters, are highly prejudicial to the progress of scarlet fever. I have already (p. 109) briefly alluded to this subject, and have mentioned the exceedingly severe cases that I have met with in ill-drained localities. Mr. Liddle, late Medical Officer to the parish of Whitechapel, informs me, that one-fourth of the total number of deaths that happened amongst the poor under his care, during the last epidemic, occurred in one or two small courts which are the worst drained in his district. The result must not, however, be attributed to the bad ventilation and drainage alone, but due allowance must be made for the depressing and debilitating effects of poor food, scanty clothing, and of the general neglect, but too frequently evinced by the poor towards their offspring.

The late Dr. Robert Williams, in his lucid and elaborate work on Morbid Poisons, observes, under the head of predisposing causes of scarlatina (p. 117), "scarlet fever has been observed to spread more universally, and with greater fatality, among the poorer than among the wealthier classes of society; and, consequently, it may be inferred, that bad diet, exposure, and the usually admitted train of debilitating causes, greatly predispose to the reception of this poison." It would be useless to quote the opinions of most writers on the subject, or to attempt to prove this position by reference to many very voluminous Tables which I have extracted, or compiled from those in the Annual Reports of the Registrar-General; but I cannot refrain from exhibiting one small Table which shows this point in a very strong light.

POPULATION ENUMERATED IN 1841.

	Metropolis and districts of 25 Towns.	District of 12 Counties.
Population	3,759,186	3,440,501
Deaths from Scarlatina in four years	14,267	6,300
Annual Mortality from Scarlatina to 1,000,000 living ...	988	478

This Table indicates, that in the metropolis, and in districts of twenty-five towns, having a population, at the census of 1841, of 3,759,186, no less than 14,267 deaths occurred from scarlet fever, its complications and sequelæ during four years; whilst in the same period of time, only 6,300 deaths from the same disease happened in twelve counties with a population of 3,440,501; or, taking the average mortality to 1,000,000 of living, we find that 988 died in the town districts, to 478 in the country districts. Can stronger proof be afforded of the evil results of overcrowding, bad ventilation, and bad drainage, than is here shown; for we well know, that as regards food, the children of the poor in towns are ordinarily better fed than the children of the poor in the country, and yet the mortality in the former was double that of the latter.

B. c. It is impossible to procure any data sufficiently extensive to show the frequency with which scarlet fever attacks persons of different age; but some approximation may be obtained from a consideration of those Tables of Registrars-General for the years 1842-46, which indicate the mortality from the disease at the different periods of life. These Tables are not deduced from the deaths in the whole of England and Wales, but from the deaths within the limits of the bills of mortality for the metropolis.

FOR THE METROPOLIS.

Deaths from Scarlatina, Years 1842-46.

Ages.	1/3	3/5	Total under 5 years.	5/10	10/15	15/20		Total above 20.
	2760	2176	5478	1856	306	78	7718	415

Deaths per Cent. from all causes, 1838-44.

		3/5	Total under 5 years.	5/10	10/15	15/20	Total.
20·625	15·504	6·516	42·645	1·189	0·473	0·690	44·997

N.B. 0/1 signifies, one year and under; 1/3 signifies three years and above one, &c.

This Table shows, that out of 8,133 deaths from scarlet fever, 7,718 occurred in persons who were under twenty years of age, and 5,478 in children who were under five years of age. It also shows, that although ordinarily, by far the greatest mortality at any age, (viz. above 20 per cent. of the total number of deaths,) happens in infants who are less than one year old, that but little comparatively of this very large mortality is produced by scarlet fever; and also, that whilst the total number of deaths decrease as the age increases up to three years, the mortality from scarlatina pursues an opposite course. It also shows, that by far the greatest number of deaths from this disease happen between the first and third birth-days, and next between the third and fifth. The next greatest mortality occurs in children who are under one year old, whilst in those who are above five, the mortality decreases as the age increases.

On comparing the number of deaths from scarlet fever, with the number of deaths from all causes, at the different ages, we arrive at very different conclusions from the above, as the greatest number of deaths from this disease, in proportion to the gross amount from all causes, occurs between the ages of five and ten; next, between ten and fifteen,

then between three and five; next between one and three; next, between fifteen and twenty; and, lastly, under one year.

We may say, that the gross mortality from scarlatina is greatest between the ages of one and three years; but that, compared with the total number of deaths from all causes, it is greatest between the ages of five and ten years.

(To be continued.)

BITE OF A RATTLE-SNAKE.

By ARTHUR BAILLIE, Esq., M.R.C.S. Lond.
The Missions of Upata, Venezuela.

Francisco, the subject of the case, was a strong muscular Indian peon, 45 years of age. He was about one hundred yards from the house when a rattle-snake wounded him. In a few seconds the pain extended up the limb, followed by loss of sight and a feeling of intoxication.

The people observed him throwing his arms about him in a strange and violent manner, calling for assistance, and saying that some animal had bitten him. Before they could reach the place he fell prostrate on the ground.

May 11, Friday, 7 p.m.—Not more than fifteen or twenty minutes have elapsed since he was empoisoned. He is supported between two persons, and is completely powerless, having no control over the upper or lower extremities; the countenance is livid, or darker than usual; appears in a lethargic state, requiring to be spoken to in a loud tone; but, when aroused, answers questions distinctly; complains of blindness, and severe pains in the *right* ankle, extending up the limb and all over his body. There are two small punctured wounds, situated perpendicularly an inch apart, equi-distant between the tendi-achillis and the external malleolus. The extremities are cold, and the pulse is quite lost at the wrists. I directed the wounds to be bathed with lime-juice, and administered Pulv. Ipecac. Comp., gr. x.

Half-past seven.—The drowsiness has disappeared; he is now able to converse with his companions, the extremities are warmer, and a very slow, small, thread-like pulse is distinguishable; shortly after he vomited with great violence, (he dined at six o'clock.) The bowels acted simultaneously, and his bladder expelled its contents. It appeared to me that an intense degree of gastro-intestinal irritation existed, manifested by spasmodic contractions of the alimentary canal and the bladder. Vomiting, tenesmus, and stranguary continued without intermission nearly two hours; the thirst was excessive, and the water he drank was immediately ejected, or passed in limpid urine. The quantity secreted was really surprising. Once I endeavoured to control the spasms, and gave him tinct. opii, ♏ 50, which was not retained.

Half-past nine.—The vomiting has ceased; complains of pain in the stomach and great thirst. Tenesmus and micturition disturbs him every few minutes. The extremities are not very warm, pulse fuller but slow. Rep. tinct. opii, ♏ 50.

Ten o'clock.—The pulse is improving, the extremities are warmer, and the pains are less.

Half-past eleven.—He has passed some blood with mucus, per anum, and has also expectorated about half an ounce more of a florid colour with the sputa; (a) he is extremely restless, has thrown off all his clothing, and rolls about in great agony. The pain is now concentrated at the epigastrium, the fingers are cold, and the general temperature of the body is diminishing; the pulse is smaller, slow, and sinking. Rep. tinct. opii, ♏60.

During the succeeding hour there was a gradual improvement of all the symptoms, and he finally ceased to answer me and fell asleep. The perspiration was suppressed from the commencement; the respiration natural, and, until the last hour, his voice was clear and sonorous.

12th, four a.m.—My patient is dressed and sitting in his hammock; the pulse is full and quick; he has been perspiring freely, and appears excited and loquacious. Ordered him some strong coffee with milk, and desired the people to leave him.

10 o'clock, a.m.—He has had some sleep, and is much better, complains of pains in the arms, and wounded ankle, which is a little swelled and tender. Says, that with the *right* eye, he is unable to see objects. Has lost the power of raising the upper lid, owing to the levator muscle being paralyzed. The conjunctiva is a little injected. There is a red zone a line and a half broad round the cornea. The pupil is extremely *contracted*, and the aqueous humour looks cloudy. The vision of the left eye is indistinct, as if a film was interposed before the object; the conjunctiva is less injected; the corneal zone is fainter; the pupil is of a grayish colour. To apply lime juice to the forehead and temples frequently. Diet, chicken broth.

13th.—He has passed a good night; the pains are relieved; feels shooting pains in the wounds; can see a little with the right eye. To have animal food, and remain quiet.

14th. He is considerably better. The amaurosis is rapidly disappearing; has been walking about the house with the aid of a stick.

15th.—He is quite well; the eyes have regained their natural appearance, and the vision is perfect. I saw him a month after in good health and condition; he still complained of slight pains or twitchings in the wounded part; and I observed he did not bear the heel firmly on the ground.

(a) I have been credibly informed that, in fatal cases, blood flows from all the natural orifices of the body.

FRACTURE OF THE SCAPULA.

By ALFRED EBSWORTH, Esq., Bulwell, Notts.

John Holland, aged 49, and Charles Wain, aged 60, were returning to their factory in a light one-horse cart, on the 16th of April, over the Bulwell forest, when the horse took fright, and ran away. It had not proceeded far before the wheel caught a sand-heap and overturned; fortunately the accident was observed from a distance by a framework-knitter, and on his arrival he found both men under the cart on their faces, and the projecting sides across the upper part of their backs, both being in nearly the same position. The fall stunned them so, they could give but an imperfect description of the occurrence. Their removal home and my attendance was simultaneous.

Holland presented the following symptoms. He was supporting the left elbow with his right hand, and the slightest alteration of posture produced excruciating pain at the top and back part of the shoulder. There was but slight alteration of form, no sinking of the joint. He had one fractured rib on the same side, causing pain on inspiration. He was so careful to retain his elbow in one position, I felt convinced fracture must exist somewhere. I began a minute examination of the clavicle; it was free; the head of the humerus was in its situation; the shaft firm. I grasped the elbow, and the patient his left hand, and then passed my fingers over the spine of the scapula. By very gentle movement I detected a fracture of the scapula extending right across the scapula from the supra-scapular notch, to the anterior inferior border. There was a great deal of extravasated blood about the fracture, preventing its ready detection.

The treatment I adopted consisted in applying a large leather plaster over the scapula. Then I stuffed the foot of a stocking, and placed the heel in the axilla, securing it by a bandage round the neck. The elbow was supported by a sling, and over this I passed a broad-rib bandage, which retained the arm firmly *in situ*, and also impeded the action of the ribs. Opiates were given to allay the cough, and the patient was supported in bed by a bed-rest. It was some two months before the bone united, and nearly four before he could raise his arm sufficiently to follow his usual occupation.

In Charles Wain's case the scapula was fractured much further back, and presented a wide gap to the feel, the broken portion being detached, and beneath were three or four ribs broken and penetrating the pleura. The patient I feared would not rally, so complicated did the injury appear; but he was one of those resigned, patient men who obey every injunction of their surgeons, and in the position in which I fixed his arm and body, he remained for nearly three weeks, and you could not have noted a deviation from it. This case I kept constantly under the influence of opium; and only procured a motion when absolutely necessary, for fear of disturbing the parts affected. At this time, August the 13th, the patient has recovered the entire use of his arm, though an over-exertion will cause pain. The broken portions are fairly united by bone, and you could hardly find out that fracture had existed, but for a slight depression on the spine of the scapula.

These cases are of rare occurrence, and I believe seldom happen but from direct violence to the bone itself. The neck, however, may be fractured, by force applied to the arm. The treatment is simple in the extreme. You place a stout pad in the axilla, throw the elbow back, and support it with a sling; and bind the arm to the side with a broad-rib bandage. A plaster over the scapula is useful, but not essential. For a long time the parts must be kept at rest, otherwise you will have a cartilaginous union, and a very incomplete motion of the arm.

FRACTURE OF BOTH CLAVICLES.

Isaac Shaycroft, collier, when at work at the Underhill Colliery, was struck by an immense coal on the right shoulder; and when this was removed, and I examined him at home, I found total inability to move either arm; he was almost doubled up, his thighs supporting his elbows, and his body bent forward. In themselves, fractures of the clavicle are not worth noting, and the complication only requires a remark here. It seldom occurs that both are broken at the same moment; then the patient places both arms across his body, and draws his thighs up to support these. In the treatment, you merely place pads in the axillæ, and support the elbows and arms with pillows. The patient can do nothing for himself for several days, so you have to feed him and attend to every want.

The Use of Glycerine in Deafness.—Amongst the many cases in which I have employed this remedy, the following may be interesting to the Profession:—

Mrs. Thorpe, of Bulwell, deaf for 18 years.—Can hear but very imperfectly in one ear, and not at all in the other; the membrana tympani destroyed, and a slight discharge oozing from the meatus. After the first application of glycerine, a marked improvement had taken place; she could hear better, and voices appeared much more distinct; on the third and fourth application she heard my watch tick plainly in one, and indistinctly in the other ear. I confidently looked forward to a cure. The sixth application she could hear *distinctly* my watch tick in *both* ears. I was delighted with the remedy, and looked forward to a provincial repute as an ear doctor; but, alas! the frailty of human hopes,—*my watch had stopped, I forgot to wind it up over-night!*

ON CHOLERA.

By R. B. RICHMOND, M.D.

Before stating the plan I adopt for the treatment of cholera, it is necessary that I should premise, for the sake of removing error and prejudice, that the benefit to be derived from the administration of a stimulant does not depend on the degree of the stimulation produced, but on its particular *quality*. For however general the effect of a stimulant may be, there is always some organ, or class of organs, on which its action more particularly falls, as, for instance, camphor on the urinary organs, or arsenic upon the gullet, &c.; and, with regard to many external applications which have been erroneously included under the general appellation of *counter-irritant;* their efficacy does not so much depend on their power, or strength, or the degree of rubescence they produce, as on the peculiarity of their action,—many of them being productive of an action *sui generis*, and exercising a specific influence on the organs over which they are applied, either by causing a *metastasis* of the diseased action to the surface, or by setting up an ac-

tion which is incompatible with that of the disease. Therefore, ought they to be called *local alteratives?* The plan to which I allude, is, on first seeing the patient, immediately to administer two or three glasses of good port-wine, put into a tumbler, and drank off cold and undiluted; then, if the case be severe, to order from 7 to 10 grains of calomel with as much Dover's-powder; and, at all events, every ten, fifteen, or twenty minutes, alternated with port-wine, a tablespoonful of the following mixture:—

℞ Spt. æth. nitrici; tinct. cardam. comp. aa ℥ i.; tinct. camph., tinct. gentianæ, tinct. zingib. aa ℥ i s.; tinct. benzoin. comp., tinct. rhei, spt. ammon. aro mat. aa ʒ ij.; tinct. catechu, vini ipecac. aa ʒi.; pulv. boratis sodæ, oxidi bismuthi, aa ℥ i.

Sig. To be taken, as directed, in a little cold water, shaking the phial.

The Profession will excuse me for presenting them thus with a *farrago;* but I always find that the greatest benefit is to be gained by a judicious combination of medicines, and by attacking the disease at all points. Besides the use of soothing and astringent remedies for the internal surface of the intestines, you are not likely to check the increased determination of the fluids then without injury, unless, at the same time, you open the channels of the skin and the kidneys.

In common bilious diarrhœa, or cholera, one teaspoonful only of the same mixture is to be given every hour, or oftener, as the case may require, and alternated with a little burnt brandy and six or eight drops of laudanum added, at one time, or with a glass of port wine at another. The same dose of the mixture may also be given after each evacuation.

In dysentery, a tablespoonful is occasionally to be administered, alternated with half a teaspoonful of Gregory's powder in a little cold water; but, in this case, both brandy and port wine are inadmissible, unless in some chronic states; but good ale or Marsala wine may, in dysentery, be taken with advantage.

In severe cases of cholera, if the abdominal pain be obstinate and persevering, and the diarrhœa be inclined occasionally to recur, notwithstanding the above means, then no time should be lost in bringing the excitement or irritation, call it what you please, from the internal membrane of the intestines to the surface. This can easily be done in most cases, short of direct sinking, by the use of the the ointment of the tartrate of antimony, which causes a real metastasis of the diseased action.

It is not generally known that, by the combination of this preparation with opium, the eruption from it is rendered milder in direct proportion to the quantity of the opium employed, and that, too without in the least lowering the standard of its beneficial effects; neither is it known that camphor and turpentine have great power in hastening the appearance of the rash, which may, by proper management, be made to come out in a surprisingly short time.

The formula which answers the purpose best (and I have ordered the ointment almost every day for the quarter of a century) is the following:—

℞ Pulv. tart. antimonii; pulv. Camph. aa. ʒss.; pulv. opii, ℈j.; ungt. resinosi, ℥i.; ol. terebinth, ℥iss.; ol. cajeput, ʒss. M. ft. unguentum.

Let some of this ointment be freely rubbed in over the seat of the pain, and this is to be continued till the skin become red, and almost as long as the friction can be borne. The rubbings must be repeated from time to time, in urgent cases, at short intervals, to keep up the redness of the skin, till the eruption makes its appearance, upon which the pain and diarrhœa will generally cease. The eruption is to be promoted by applying, in the intervals between the rubbings, a cloth spread with some of the ointment. When the rash comes sufficiently out, a cloth, with a little spermaceti ointment may be placed over it, or it may be dredged, when hot or irritable, with a little farina or hair-powder. It ought not, at first, to be allowed to go in, or to die away suddenly; and, when this happens, the rash can be easily renewed by again applying the tartar-emetic ointment-cloth over the place for a short time.

If the patient's tongue be much furred with the fever-whiteness, indicating iritation and derangement of the mucous membranes; the disease, however often it may be relieved, or for a time removed, will constantly recur.

For the improvement of the state of the mucous membranes, and of the digestive organs generally, I find nothing so beneficial as the combination of these three nitrates with columba and canella, in the following form:—

℞ Pulv. nitratis argenti, gr. iij.; pulv. nitratis potassæ, gr. vi.; pulv. tris nitratis bismuth, ʒij.; pulv. columbæ bismuthi, ʒj.; canillæ albæ, ʒss.; et in pulv. No. xij; divide. M. sig.; a half powder thrice a day, mixed with a little wine, and water added.

In cases of great weakness some quinine may be added, and, where the skin is dry, a very small dose of ipecacuanha. Previous to the discovery of the efficacy of large draughts of port-wine, which discovery I must certainly claim as my own, I had frequently attempted the alleviation of the spasms in vain by large doses, and combinations of the most powerful antispasmodics, with diffusible and permanent stimulants; but I have never, in one instance, seen a large draught of undiluted, cold port-wine fail to carry the spasms off in less than a minute's time. On being called to patients, I have frequently found that, before I had time to reach them, they had indulged in large potations of brandy and hot water, strong ale, and various other stimulants, without obtaining the least relief. So far from this, it is, on the contrary, to be remarked, that brandy and hot water, or, indeed, any other hot drink, which in bilious diarrhœa and common colic, would have a tendency to give relief, seldom fail, in the true Asiatic cholera, to aggravate the abdominal pain; while they exercise little or no influence on the spasms. This effect of hot drinks, and particularly of brandy and hot water, may be added to the other *diagnostic* signs of the disease.

Since I have commenced to give port wine in draughts of a half pint tumbler full at once, I have scarcely had occasion to order any other medicine, with the exception, occasionally, of the eruptive ointment, and the nitrates for the state of the membranes.

It could scarcely, *a priori*, be credited, that such a mild stimulus as port-wine, which one would suppose would be liable to become acid on the stomach, should exercise such an immediate effect on the very seat of the disease.

No sooner is the above quantity swallowed, than the spasms, pain, vomiting, and diarrhœa, instantly cease. This effect of port-wine may be set down as another *diagnostic* of the genuineness of the disease.

If, however, the stomach be burdened with any remedies previously taken, or food undigested, phlegm or the like, the first effect of the port-wine, is to enable the stomach to throw them off; so parsimonious does the system appear to be of the wine, that pure mucus, or the rice-water-like fluid, will often come up, without being so much as tinged by the colour of the port that has just been swallowed Some of those physiologists, who believe that al the processes of a *vital system* are carried on by chemical laws, will, perhaps, explain this fact.

To conclude, I would say, were the word *specific* fashionable in legitimate medical language, that, in Asiatic cholera, port-wine, in sufficient quantity, is decidedly a specific.

Hitherto I have said little respecting the collapse, in which, when it is allowed to supervene, no time is to be lost.

If the patient can swallow, the same dose of port wine, with a drachm of sulphuric ether, two of tinc ture of cayenne, and a wine-glassful of brandy in it is instantly to be given at one draught; sinapisms along the spine; bottles of boiling water, or bladders filled, ought to be placed on the regions of the heart and stomach, and to the loins and feet, after epithems of heated flannels, over which turpentine has been poured, are first applied. The patient may also be well steamed, as practised in Russia, and described in "A. B. G.'s" letter in the *Times* newspaper of the 8th of August.

If the patient be asphyxiated, then, in addition to the above, a blister, or sinapism, is to be placed on the nape of the neck, and a current of electricity or galvanism passed along the course of the pneumogastric nerve, or even artificial respiration kept up, as in cases of drowning; and when the patient cannot swallow, the remedies above-named ought then to be thrown into the stomach, with the stomach pump, and the patient's back placed at a strong fire, till symptoms of uneasiness and returning life be manifested.

10, Red Lion-square, August 27, 1849.

HOSPITAL REPORTS.

LONDON HOSPITAL.

Reported by J. BROWN, Esq.

Case I.

A LARGE NÆVUS OF THE LOWER LIP REMOVED BY LIGATURES.

January 4, 1848.—Wm. Fletcher, a bricklayer, aged 23 years, was admitted into the London Hospital, under the care of Mr. Luke, desiring to be relieved of the incumbrance arising from an immensely enlarged lower lip, caused by a nævus, which had existed from his earliest recollection.

An attempt was made by Mr. Luke, in 1843, to arrest the development of the disease, by the passage of a series of threads through it, which, having caused considerable inflammation, was attended by temporary success. Of late, however, the lip has rapidly and enormously increased, and has given rise to very great annoyance, both in speaking and taking food. There is also extensive discolouration of the skin, over the lower part of the face, the neck, and upper part of the chest; but this was not in progress of extension and gave no inconvenience. For the purpose of removing the large mass of diseased lip, Mr. Luke adopted the following proceeding:—

A ligature, three yards in length, was armed with nine curved needles, which were placed about twelve inches apart from each other. The first needle was passed through the lip, from its inside near the left angle, a little beyond the limits of the tumor; the second, through the lip at a little distance to the right; the third, about the same distance, still more to the right; and so on with the other needles, until the right angle was reached, the last needle being passed a little beyond the tumor on the right side. In this way seven of the needles were used; the remaining two, being unnecessary, were removed. The needles were next cut off, and eight loops of ligature were thus left. Upon tightly tying the ends of these loops, respectively, with each other, the whole of the tumor was enclosed within them, and its circulation stopped. This was done, most effectively, by reason of each ligature embracing a small portion only of the lip, a proceeding which had the additional advantage of not producing any puckering or drawing in of the lip.

January 10th.—The patient to-day complains of pain in the lip, which is greatly distended, and its insulated part is of a shining livid colour.

℞ Vin. opii, ʒij.; aq. font, Oj.; ft. lotio. This lotion to be kept constantly on the part.

℞ Morph. acet., gr. ss; conf. aromat., gr. iv.; Ft. pil. horâ somni sumend. Diet, milk and beef-tea.

13th.—Since last report an incision has been made through the livid swelling with a lancet, which has had the desired effect of relieving the tension and pain; a bread poultice, made with opiate lotion, is to be kept constantly on the lip, and the morphia pill to be continued at bed-time.

16th.—Less pain in the tumour, which is becoming black.

19th.—The tumour sloughed off yesterday, leaving the sore with a pretty sound and healthy appearance. A compress of lint is to be put over the lower part of the lip, and firmly fixed by a long piece of adhesive plaster, with the view of supporting the lip and assisting the process of cicatrization.

February 19th.—The lip has been healed for some time, and the patient has this day been discharged from the hospital cured. The deformity caused by the tumour, with the exception of the mere mark of the cicatrix, has, by this operation, been completely and satisfactorily removed, while the patient, possessing the power of free motion of the lip, has got rid of an inconvenience which had hitherto rendered his life miserable.

Case II.

EMPHYSEMA FROM FRACTURED RIBS.

July 27, 1848.—James Davey, aged 68 years, a labourer in the London Docks, received a blow this morning while in the performance of his duty, upon the right side of his chest, by a hogshead of sugar, which was swinging from a crane, and, as he appeared to be suffering great pain, he was immediately brought to this Hospital for treatment.

On examination, no fracture of any of the ribs could be detected, on account of the tumefaction which had taken place around the injured part; but as, from the symptoms, there could be no doubt that the man had received a serious injury, he was at once taken into the Accident Ward, and placed under the care of Mr. Luke.

At half-past ten o'clock, p.m. (nine hours after his admission into the Hospital), no change had taken place in the symptoms. The pulse was slow and weak; the breathing difficult. The body was covered with hot perspiration, and the patient said that the only position which in any way relieved the pain, or, indeed, in which he could lie, was upon the side opposite to the one injured, with his back bent forwards, and his thighs flexed upon the abdomen; and he also said, that the pain, while in this position, was much less severe than it was in the morning at the time he applied at the Hospital for assistance. In less than half an hour after this, however, the nurse reported that his body had become, to use his own expression, "swollen like a drum;" and on revisiting him, it was found that extensive emphysema had suddenly taken place; the cellular tissue over the whole of the body, from the head to the inferior extremities being distended with air. The neck, scrotum, scalp, and face, were greatly swollen. The eyes were completely closed. The body, in point of temperature, was below the natural standard. The pulse had now become quick and full; the breathing very difficult and labouring, and, at each expiration, the distension above the immediate seat of the injury, was perceptibly increased. Twenty-five ounces of blood were now taken, which seemed, at the time, greatly to relieve him. On the following morning, at six o'clock, the emphysematous swelling had greatly increased, particularly about the scrotum and over the chest. Punctures were now made in those parts, through which the air passed freely; but the patient appeared to be much exhausted. The pulse was weak and irregular. The breathing short and difficult. The body, which was cold, was covered with a clammy perspiration, and, in this state, the patient remained until half-past seven o'clock, when he died.

Treatment.—The bowels were at first freely opened by cathartics. The side was fomented with warm water. Bloodletting was next had recourse to; the most distended parts were then punctured for the purpose of permitting the air to escape from the cellular tissue, and wine, brandy, and ammonia were internally administered.

Post-mortem Appearances.—On dissecting back the integuments from the sternum, over the anterior part of the chest, and making a small opening into the thorax, between the ribs, on the right side, a considerable quantity of air rushed out. Six of the ribs were found to be broken, and the fractured extremity of one of them was depressed. On removing the sternum, the pleura was found to be lacerated, and the right lung slightly wounded. The lung, which was collapsed, was of the natural colour in some parts, and, in other places, it was dark and congested. Some of the air-cells were filled with coagulated blood, and a quantity of effused blood was found in the right pleura. The left lung was sound.

Case III.

HÆMORRHAGE FROM THE TONGUE TREATED WITH TINCTURE OF MATICO, AFTER OTHER MEANS HAD FAILED.

October 9, 1848.—William Baker, fruiterer, aged 34 years, states that, on the 6th instant, he received a blow upon the chin, whilst the tongue was protruding from the mouth, which caused that organ to be wounded by the teeth; the consequence of which was, hæmorrhage, so copious and uncontrollable, as to render it necessary to apply to several surgeons for assistance; but, as none of them succeeded in suppressing the bleeding, he was brought to this Hospital in a very weak state, and placed under the care of Mr. Luke. A piece of the nitrate of silver was immediately pushed into the wound; but, notwithstanding this, the bleeding still continued. A saturated solution of alum was next applied by means of pieces of lint, but still without success; and, at last, the tincture of matico was had recourse to, and used in the sameway as the solution of alum, which, fortunately, had the desired effect of permanently arresting the hæmorrhage.

The patient states, that, whenever bleeding from his nose takes place, it generally continues for several days; that some time ago, when he was bled from the arm, it was found to be very difficult to stop the blood, which oozed through the compress and bandage for nearly four days. He further states, that he was a patient in this Hospital some years back, on account of hæmorrhage from the urethra, which continued for the space of seven days, and was, at last, stopped by keeping a large catheter for a long time in the urethra. He had also been, it appears, at another time, in this Hospital, in consequence of having received a wound on his hand, which bled for several days, notwithstanding continual pressure was kept up by compresses; thus showing a very strong hæmorrhagic diathesis; and, on inquiry, it is found, that all the members of his family have the same disposition, particularly his father.

In the above case, the patient, after having been one week in the Hospital, without any return of the hæmorrhage, was discharged, with directions to take tonic medicines, and to use such other means as are likely to have a tendency to strengthen his constitution and to improve his general health.

University of London.—First Examination for the Degree of M.B., 1849.—Examination for Honours.—Anatomy and Physiology.—Pardey, Charles, Exhibition and Gold Medal, King's College; Thompson, Henry, Gold Medal, University College; Neale, Richard, University College; Duthoit, Thomas James, St. Bartholomew's Hospital; May, George, King's College; Langham, John Phillipson, University College; Head, Edward Abraham Hancock, King's College. Chemistry.—Pardey, Charles, Gold Medal, King's College; Odling, William, Gold Medal, Guy's Hospital; Head, Edward Abraham Handcock, King's College; Thompson, Henry, University College. Materia Medica and Pharmaceutical Chemistry.—May, George, Exhibition and Gold Medal, King's College; Odling, William, Gold Medal, Guy's Hospital; Pardey, Charles, King's College; Houlton, Joseph, Charing-cross Hospital; Neale, Richard, University College; Head, Edward Abraham Hancock, King's College; Stocker, John Sherwood, Guy's Hospital. Botany.—Pardey, Charles, Gold Medal, King's College; Neale, Richard, University College; Odling, William, Guy's Hospital.

National Institute.—We understand that the Council of the National Institute are desirous of having a conference with delegates from the various Associations that have been organised for the purpose of effecting a Reform of the Medical Profession, and that they intend forwarding a Circular Letter to the officials of such Associations, and other influential gentlemen, for the purpose. It is clear, that no satisfactory means of reform can be carried out, unless there is a general agreement among all parties, both in and out of the governing bodies of our Collegiate Institutions. We, therefore, hope that this laudable design will meet with success.

PROGRESS OF MEDICAL SCIENCE.

FRANCE.

[From our Paris Correspondent.]

THE NATIONAL EXHIBITION.

According to promise, I complete my account of the things pertaining to medical science which are to be found in this wonderful collection of useful and agreeable objects.

Before proceeding, however, to notice the chemical and pharmaceutical products which decorate the stand in vast abundance, I beg to say a few additional words on M. Bloch's syphon, partly because I gave you a very imperfect description of this ingenious instrument, and partly because the inventor has substituted a new instrument for the original one. The accompanying sketches will give a clearer idea of both than words could convey.

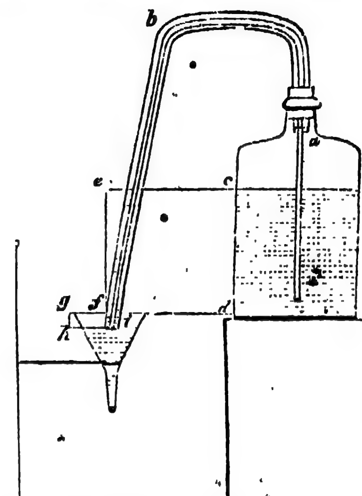

Fig. 1 represents the original syphon. It is fixed and set to work in the ordinary manner, and the filter placed so that the extremity of the "regulating tube" *b* shall just skim the surface of the fluid. As the air enters through the extremity of the tube *b*, the internal tube or syphon will act from the pressure of the column *c d* + the difference of the two branches, *g h*. When the fluid ascends in the filter, and the extremity of the regulating tube becomes closed by it, the fluid will continue to ascend in the tube *b*, until the pressure of the internal air + those of the columns *c d* and *g h* are equal to that of the atmosphere; or as *c d* and *g h* are equal to *e f* and *f i*, until the fluid rises in the tube *b* to *e f*.

As soon as the level in the filter falls by the discharge of fluid from its apex, then the column *e f* suddenly falls, the air rushes in, and intermittence takes place.

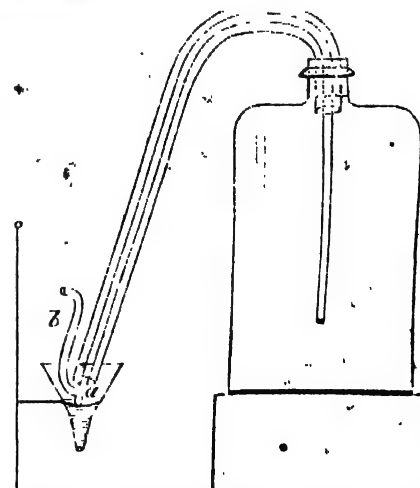

Figure 2 represents a modification of the instrument, which has been substituted for the original

within the last week. The inner tube, or syphon is bent on itself, as it comes out from the "regulator," and gives off, at the bend, a small tube, *a*, which projects about two centimetres into the fluid contained in the filter. The use of the ascending branch, *b*, appears to be, to afford a means o making the syphon act readily by suction.

When I saw this instrument in action, the fluid was escaping by drops from the tube *a*, which did not project into the fluid of the filter, and the only intermittence was that of the intervals between the drops. The price of the syphon varies from 3 to 5 francs.

CHEMICAL AND PHARMACEUTICAL PRODUCTS.

In the vast Palace of the Champs Elysées two divisions, or "stands," as we would call them, are set aside for the display of Pharmaceutical and Chemical productions.

No less than eighty houses, the principal of Paris, France, and Algiers, have furnished specimens, amongst which the great difficulty is "to choose."

The firm of Boyveau, Pelletier, and Co., however, appear to me to bear off the palm. In the division occupied by the products of this celebrated establishment, are four shelves loaded with the most beautiful specimens of chemical industry.

On the first shelf we are attracted by an immense jar of cafeine, flanked by large bottles, containing iodide of lead, sulphate of cadmium, and iodide of mercury, of a most brilliant colour.

On the second shelf we have, in equally large proportions, jars containing the hydriodate of morphine, crystalized urea, cyanide of potassium and iron, calomel *à la vapeur*, sulphate of ammonia and nickel, of a most delicate green, iodide of potassium, and bisulphate of tin, which looks like native gold.

The third shelf contains, in the middle, a beautiful basket formed of a crystallized acetate of copper, the ammonio-nitrate of copper, tartrate of potass, a large jar of the hyposulphate of soda, so useful for daguerreotyping, chromate of potass, and smaller jars containing manganate of potass, chloride of chromium, of a superb lilac tint, and the oxide of nickel.

Finally, on the fourth shelf, are ranged, sulphate of morphia, gallic acid, uric acid, alloxane, crystallized chloride of barium, parabanic acid, and the products of uric acid in four small bottles.

Messrs. Pelletier and Co., likewise exhibit a mercurial trough, for the analysis of gases by a new process.

Not far from the latter is a fine electric battery, by Quennessen, for the production of electric light. It is a jar battery of 40 elements, which, the manufacturer assures us, are equal to 150 elements of Bunsen. It costs 500 francs, or 20*l*.

Worthy of notice, also, is a balance which receives a weight of 4½ pounds, yet is delicate enough to indicate a difference of ·01544 grains Troy. This costs 32*l*.

The mines of Bouxwiller furnish many fine specimens of chemical product, but they are rather destined for the arts than for medicine. Suffice it, therefore, to notice two enormous specimens of the chromate of potass, in the form of a cross and of a long-necked bottle; three varieties of the sulphate of iron, white and gray ammonia in large masses, and enormous blocks of alum.

The establishment at Noisel sends some fine specimens of extracts prepared *in vacuo*, especially extracts of bark, Ipecacuanha, and cicuta.

Lemire, of Choisy-le-Roy, also exhibits a variety of products which do high credit to provincial industry. His specimens of the products from the distillation of wood are complete and interesting. Amongst these I may notice the liquid gas, which is perfectly clear—oil of coal less so; the spirit of turf, of a light amber colour and spirit of wood, perfectly clear. A curious specimen from the same manufactory is a glass bottle divided into three compartments, and containing the three elements of naphtha. Bitumen, naphtha, and calcaire, of black, grey, and white colours.

The products of the distillation of naphtha, exhibited by M. Lemire are, the fat of naphtha, bitumen, various oily fluids of a yellow colour; petroleum and white naphtha, perfectly colourless. He has likewise a superb specimen of acetate of copper, two varieties of the tartrate of potass and iron, and a fine jar of anhydrous phosphoric acid.

As you may readily perceive, it would require an intimate knowledge of chemical and pharmaceutical mysteries to appreciate all these products in a suitable manner.

The only specimens of M. Pelouze which struck me as being worthy of notice were, an immense jar of tannin and some pyrolignate of lead.

M. Cournerie and Co., of Cherbourg, exhibit two varieties of the iodide of lead, some biniodide of mercury of a superb red colour, and a large quantity of sublimed iodine. They have also fine specimens of the iodide of potassium in crystallized masses, brilliant and white as wax. Campion and Therouđe, of Granville, exhibit very fine specimens likewise of pure iodine, iodide of potassium, and of the sulphates and muriates of potass. Jůlien, of Paris, who has already received honorary distinction, has some arsenite of copper and corrosive sublimate, which appear worthy of notice.

M. M. Rousseau, the well-known chemists of the *Rue de l'Ecole de Médicine*, exhibit chiefly a number of rare and costly oxides for colouring glass and artificial jewels.

MM. Kuhlmann, of Amiens, have a large collection of acids and compounds of soda; M. Huillard, some sulphate of alumina, perfectly free from iron; and M. Biron, a large jar of crystallised mannite. Homalle and Quevenne, of the *Rue Jacob*, exhibit a large jar of digitaline, with a quantity of small pills formed of this substance.

M. Leroux has an equally large mass of salicine, the active principle of the willow bark, the febrifuge powers of which, he says, he was the first to have made known in the year 1829. Amongst the pharmaceutical curiosities, I should not omit to mention the enormous gluten buns of M. Pavart, for the treatment of diabetes, and the "capsule boxes" of M. Lilberman. These latter contain oblong capsules, made of vegetable mucilage, which open and shut ike a box, and in which the medicine is placed immediately before being taken. Unlike other capsules f a like kind, they are empty, which probably constitutes their chief value. They are sold for the moderate price of 2s. 6d. per hundred. Lastly, I should mention the vast quantities of gelatine, of every colour and degree of purity, from 1s. 8d. o 10d. per pound. Perhaps, however, the most nteresting part of the whole exhibition is that devoted to the productions of Africa; but, the only products which come within the range of medicine are some specimens of opium, castor-oil, rhubarb, and citric acid, from the Government gardens and he establishments of MM. Baziere, Simounet, and Rozeron, of Algiers.

While on the subject of Chemistry I may mention, that M. Melsens, the young Belgian chemist, whose name has acquired such notoriety from the sugar question, has published an interesting paper on

THE USE OF IODIDE OF POTASSIUM IN AFFECTIONS FROM LEAD AND MERCURY.

M. Melsens thinks that, in many cases, where the symptoms of poisoning from these metals continue after the removal of the patient from the exciting cause of the complaint, the metals continue fixed in he tissue of the diseased organs. Mercury forms a variety of compounds; and lead occurs, according o our author, chiefly as a plombate of soda.

Reasoning from these principles, M. Melsens proposes "to render soluble the metallic compounds which are fixed in the tissues, and favour their excretion by uniting with them another substance—the iodide of potassium, which is readily eliminated. This idea, for lead at least, is founded on a principle exactly contrary to that of the practitioners who adopt the acid treatment with "sulphuric lemonade;" for here the lead is supposed to exist under the form of a soluble salt, and the acid is used to convert it into an insoluble sulphate of lead.

M. Melsens has proved, by experiments conducted on his own person during two months, that the iodide is eliminated through nearly all the emunctories; he found it even in the saliva and tears; the fæces, on the contrary, do not contain any trace.

For the practical part of the subject, M. Melsens relates four cases of lead colic cured by the iodide of potassium, and six cases of mercurial poisoning in gilders, &c., five of which terminated favourably.

To adopt M. Melsens' theory, we would naturally require proof that the metallic particles have become soluble in the tissues, and been expelled with the iodide. To prove this, M. Melsens cites the very curious, and perhaps unique, fact, "that, in all the cases of chronic poisoning from lead and mercury, in which the iodine was employed, the cure was preceded by acute symptoms of poisoning from these metals. As to the direct proof of their presence in the excretions, M. Melsens mentions only one case, that of a glass-maker, in whose urine mercury was found. It will be for experience to decide on the practical value of M. Melsens' discovery. His theory does not seem free from reproach, though, if I remember right, the presence of lead in the paralysed muscles was noticed many years ago by Mr. Paget, in a paper published by the Medico-Chirurgical Society.

GERMANY.

(From our Berlin Correspondent.)

The cholera has sojourned nearly fourteen weeks among us, nor does it now seem inclined to take its departure. We have seldom less than eighty cases a day, and most of these of a very intense character; and, moreover, about a fortnight ago, it appeared for a time under so malignant a form, that the public, in their fright, forgot even their interest in the Hungarian struggle. We were, in consequence, inundated with popular and complicated essays on the cholera; and among these the readers of our most widely circulated Journals were terrified out of their wits by the information that certain individual had discovered the source of the choleric poison in the green slime which appeared on the top of drinking water when allowed to stand for twenty-four hours. This party made a proposition to the effect, that the Berlin people should abstain from drinking spring water for fourteen days, and that they would then see how the cholera would disappear. Instantaneously the hydropathists, who, notwithstanding their cold baths, douches, and wet sheetings, are here a very hot-headed sect, rose *en masse*, and declared the hydrophobist to be a mad-.n. Cold water, and nothing but cold water, must be drunk, it being the only true preservative in case of cholera. But the cholera always acts "*en souvérain*," and attacks whom it pleases, regardless whether they submit themselves to a wet or dry treatment.

You know how strictly vaccination is regarded in Prussia. No child is admitted to the schools without the cow-pox mark, and every recruit, without distinction, is vaccinated as soon as he enters the army. Lately a public announcement was made as to its results in the army, of which the following is an extract:—"In the year, 1848, 28,859 soldiers were vaccinated. With 16,882 its effects were regular; with 4,404 irregular; and with 7,573 no result was discernible.

The summer lectures at our University have been discontinued. During the last six months 1,182 students had their names subscribed, out of which number 203 belonged to the medical faculty; amongst the latter there were 50 foreigners.

You remember the experiments of Bernard in Paris, by which it appeared that an injury of the floor of the fourth cerebral ventricle in rabbits changed the character of their urine. The Paris papers made a grand report on the merits of the discovery, and considered themselves as the sources of all light on the etiology of diabetes. But, in Berlin, where we have also experimented in the same way as Dr. Bernard, no influence on the urine has been obtained.

Permit me to inform your readers of our clinical ex-

perience on collodium. Collodium has been successful on simple decubitus, and even in greater wounded surfaces. It was found to be valueless in sore breasts. A pseudo-erysipelas in the lower part of the thigh was speedily cured by the application of collodium; and Langenbeck strongly recommends it after amputation; in two or three days he removes all sutures, and applies collodium. By these means he generally effects union by the first intention.

We hear no more of a Prussian Medical Reform. This hope of the year 1848 has, like many others of the same date disappeared. The Reform Association has gone to sleep, and its Journal is given up for lack of subscribers.

In Austria, where medicine formerly enjoyed the special protection of Government, it is now neglected,— the Universities are in a sad predicament, and their professors regarded with suspicion and dislike.

The reason why a hostile feeling is thus displayed toward medical science, is that her votaries were among the chief instigators of the Austrian Revolution; and that those members of the Academical Legion of Vienna, who sought refuge in Hungary, were among the bravest in the army of General Bem. The salaries of the Professors have been greatly reduced, and they have even been deprived of their chairs, if the colours they wore were more German than Austrian; and scientific Institutions and Museums have been substantially suppressed, by being deprived of their funds. The celebrated anatomist Hyrth, of Vienna, tired of the annoyances to which he was subjected, has thrown up his Professorship; and Partreban, Professor of Physiology at Prague, during lecture, and in the midst of his auditors, was lately arrested by soldiers, on suspicion of having harboured a fugitive. On the following morning, the Professor was released, but refused every satisfaction for the injury he had sustained. He is now on his road to Paris.(a)

The Austrian army in Hungary is miserably deficient in Medical men; the reason principally is, that, in the Austrian service, a surgeon is forced to put up with a vast deal of harsh treatment. In order to remedy this deficiency, the Government has adopted a truly Austrian measure; namely, it has resolved, that no medical student shall receive his Doctor's diploma unless he binds himself in the first instance to serve some time in the army

It is, perhaps, known to you, that in the same way as the German agriculturists hold annual meetings in some German town, the naturalists and Medical men also annually congregate together. This Institution has now existed twenty-five years; and has for its object, that the Medical men and naturalists of our wide Fatherland should, whilst engaging in these festivities, impart to each other their various discoveries. The last meeting was held at Aix-la-Chapelle; but in 1848, on account of the unsettled political state of the country, there was no meeting. This year the Association is convened to meet from the 18th to the 24th of September at Ratisbonne, in Bavaria.

DENMARK.

[From our Copenhagen Correspondent.]

THE STATE OF MEDICINE IN DENMARK.

Denmark never has, and scarcely ever will be able to play any great part in the history of medical science. Its territory scarcely exceeding and its population less than that of Holland, the country has produced but few distinguished men. Another circumstance that must prove an impediment to the literature of Denmark, is the condition of its language. Copious and flexible, soft and euphonic offspring of the Norse, and sister of the ancient German, the Danish language only requires that its literature should be known to insure for it a high place among that of Europe; but the small population of Denmark, its geographical position, removed from the main road of continental communication, and the humble part which for centuries it has been compelled to play in its political relations, has consigned its language to undeserved neglect, and left its literature unnoticed and unknown among the nations.

Thus scientific men in Denmark are rarely noticed, unless they write in a foreign language. There was, indeed, a time when there seemed a disposition to make Danish medicine a branch of German science. But in later years, this has, in no small measure, emancipated herself from the systematic eccentricities of Germany, and joined issue with English and French authority. Of late, however, the political and national differences between Germany and Denmark, have left the medical literature of the latter country still more unknown to foreign nations; and thus a Danish Medical Author, writing for a small public, has the proud satisfaction of feeling, that he is perhaps actuated by a purer love of science, than if he might hope for European renown to reward his exertions.

Notwithstanding all these opposing circumstances, the names of Danish physicians are by no means unknown in the history of medicine, especially those of the olden time, when the Latin language was the common medium of scientific communication Anatomy, for instance, is indebted to the Danish physicians of the seventeenth and eighteenth centuries for many important discoveries. Thus, Thomas Bartholin, in the seventeenth century, the discoverer of the lymphatics, and the promoter of Harvey's doctrine of the circulation, was a Dane. Caspar Bartholin (the younger), and Niels Steensen (latiné Nicolaus Stenonius,) whose name is connected with the discovery of the Parotid duct, were his contemporaries; and, in the 18th century, J. B. Winslow, added much to the renown of the Danish anatomists. In the last half of the past century, H. Callisen afterwards Professor at the Academy of Surgeon wrote in Latin a system of surgery, which havin passed through many editions, became an established standard work in Europe, and still maintains a high place in the literature of surgery. The contemporaries of Callisen were M. Saxtorph, the celebrated accoucheur, late Physician to the Lying-in-house in Copenhagen; J. E. Tode and F. L. Bang, both Professors of the University, the first known voluminous author and editor of Danish and German periodicals towards the end of the past century the latter as the author of what once was reckoned among the best works on practical medicine. Among the physicians of the present century, were Professor J. D. Herholdt, a renowned physiologist, and a most distinguished man of genius and learning; J. Jacobson, the ingenious inventor of lithotriphy; J. D. Brandis, a German, indeed, but writing pathology in Denmark; and Professor Gundelach Moller, who first introduced clinical surgery to Copenhagen, a bold operator, and one of the few who have tied both the carotids.

Until 1842, medical science in Denmark, influenced by the traditional division between medicine and surgery, was taught by two different institutions. The elder of these was the *Medical Faculty of the University of Copenhagen* (founded in the year 1479,) which, till the 18th century, was the only school of medicine in the kingdom, and where, accordingly, most of the elder anatomists and physicians were educated. But medicine, properly so called, and its collateral branches being in ancient times the only objects of solid instruction at the Faculty, there was founded in the year 1736 a "*Theatrum Anatomico-Chirurgicum*" in Copenhagen, as a school for surgeons. This institution, having existed for half a century, was displaced in 1785, by the "*Royal Academy of Surgery*," founded upon a more extended plan, and similar to analogous institutions at Berlin and Vienna.

Surgery was now respectably represented in the system of medical education in Denmark. The ancient division of Medical men into physicians and surgeons, indeed, still existed, and nobody thought of uniting surgical and medical practice. Yet the Royal Academy of Surgery had a very decided and salutary influence in raising the somewhat despised study and practice of surgery in the opinion as well of the public as of the Medical Profession. Gradually improving and enlarging its original plan, the Academy of Surgery, in the course of years, became a formidable rival to the Medical Faculty; and a medical man, who had undergone the examination at the Academy alone, *cæteris paribus*, was deemed better prepared for practice, than if he had merely passed the Faculty of Medicine. The examination of the Academy, with few exceptions, entitled the "*candidate of surgery*" to the same rights as the examination of the Faculty. The "*Examen Medicini*" at the Faculty, *necessary* only to those who either aspired to the grade of a Doctor in Medicine, not conferred by the Academy, became, in later years, a mere formality, not, however, to be neglected by surgeons who, having been scholars at the University, wished to distinguish themselves.

But still the Academy of Surgery, notwithstanding its great and undisputed merits, and the improvements which, by degrees, it underwent, did not in all respects respond to the claims of the day. One of its greatest faults was that of not demanding any preparatory education from its pupils. It sent forth many a rude and ungentlemanly fellow as a practitioner, totally unfit to associate with those members of the Profession who had passed their youth in a regular school and University curriculum. It was a fault arising from the original destination of the Academy, being, to improve and raise the study of surgery, then despised by the pupils of the University; and though the number of such uncouth members of the Profession by degrees were much diminished, because everybody now began to feel the necessity of studying surgery, yet, the regulation by which any person devoid of genteel education might, by the examination at the Academy, acquire the same rights as a well-bred student, unavoidably gave rise to schism between members of the Profession. The Academy of Surgery thus, insensibly, had become an anachronism. The division between Medicine and Surgery had been long acknowledged in Denmark, as neither serving the purposes of science nor those of practical life; and the want of plan and unity in professional studies, and the differences between the Faculty and the Academy, at last proved so unnatural, that it was found necessary to unite together that which never should have been separated (a)

Considerable progress was made when, in 1838, a strict union between the Academy and the Faculty was established in such a manner that both institutions, still remaining separated as to administrative and economic matters, localities, professors, &c., yet taught upon a common plan, and constituted but one body for the purpose of examining the pupils of the Academy as well as the medical students of the University, and jointly bestowing the *jus practicandi* hitherto acquired from either. This union was preparatory to the uniting of surgery and medicine, and establishing but one class of men equally skilled in both, provided with a preparatory education, and able to command general respect and esteem for the Profession; which long and well-premeditated plan was at last carried into effect, by the complete amalgamation of the two Institutions in the year 1842 :—the Academy of Surgery being incorporated with the University, and placed under the management of a Royal University Board of Professors. The property of the Academy was incorporated with that of the University; and now the *Medical Faculty of the University* of Copenhagen is the *only* institution in the kingdom of Denmark destined for the instruction of medical men, and comprising, or at least intending to comprise, within its plan, all the branches of Medical and Surgical Science.

(a) What a fate may sometimes befal an Austrian Professor can be gleaned from the following advertisement, which appeared in the *Viener Zeitung* of the 1st of August; it was posted for four days in the street corners, and ran as follows:—"A situation as servant is wanted by a University Professor, who is at the same time an M.D. and surgeon."

(a) In the *British and Foreign Medical Review*, July, 1836, Professor Otto, of Copenhagen, has written a Report of the State of Medicine in Denmark, where an account of the Academy of Surgery, and of the Medical Faculty of the University, as they then existed, is to be found.

TO SUBSCRIBERS.

New Subscribers will oblige by forwarding their Names direct to the Office, 147, Strand, or to the News Agents or Booksellers. All Post-office Orders should be made payable to the Publishers, WM. S. ORR AND CO.

MEDICAL TIMES.

SATURDAY, SEPTEMBER 1, 1849.

IT affords us much satisfaction to see the current of public opinion setting in strongly against the custom of intramural interments. It is not because the inhabitants of this great Metropolis have been kept in ignorance of the fact of cemeteries being gorged with human bodies in various stages of decomposition, from which emanate the most noxious exhalations, that a persevering demand has not been made for their immediate closure, but because the evils inflicted were not immediately traced to their sources. Typhus fever and other fatal diseases had so long been located amongst us, that the public was slow to believe most of them were produced and perpetuated by causes easily removed. Science might have spoken in vain for many years to come, if the advent of the cholera to our shores had not roused the people from their slumbers, and inspired them with a concern for their safety. A disease apparently so singular in its movements,—so rapid in its progress,—so fatal in its results,—could not fail to command the most earnest attention from all classes in society. Curative medicine tried all its resources to conquer this strange enemy to man, but in vain,—when the long neglected science of hygiene was brought forward as a most hopeful resource. The enemy, in his movements, betrayed the secret wherein his great strength lay, and the efforts of sanitary reformers have been directed to dispossess him of his strongholds. Wherever the cupidity or stupidity of men had allowed the excretæ of the inhabitants of our towns to stagnate, or only imperfectly to be carried away, there malignant diseases played frightful havoc with human life. The champions of hygiene did well, therefore, in early directing their attention to remedy the defective condition of urban drains and sewers. But passing strange does it appear, that while other causes were discovered, equally destructive to human life, no combined or determined attack was made upon them. Among these stand prominently forth—the graveyard nuisance.

It is true that a few individuals exposed and condemned the secrets of the charnel-house—that a Parliamentary investigation more than confirmed whatever those individuals had stated; yet the "nuisance" remains to this day unabated, and the sexton and gravedigger are employed with unabated vigour in making firewood of coffins, and in chopping up partially decomposed bodies. We shall not go over the list of enormities perpetrated in the burial-grounds of Spa-fields, Portugal-street, St. Giles, St. Bride's, and other places, which have for some time been before the public, but shall take a more recent specimen from the parish of St. Ann, Blackfriars, in order to show that those who are interested in surcharging our intra-urbem cemeteries, are nothing daunted by the exposures which have been made. We feel that we have already done some good by bringing forward that filthy little golgotha from its unmerited obscurity. One would think it must have been a sweet smelling savour to the "*Times* printing-office" and Apothecaries' Hall, overshadowed as it is by these great corporations. To the parishioners in general, however, it is a stench in their nostrils, as the following Report, made to the Commissioner of the City Police last Monday, will prove:—

"Sergeant Price, 66, reports that his attention having been called by the inhabitants near the burial-ground of St. Ann's, Blackfriars, situate in Church-entry, Shoemaker-row, to an offensive nuisance existing from the insufferable smell from the grave-yard, he was directed by Inspector Scott to visit the ground, and upon doing so this afternoon (Sunday) he saw a grave opened about four feet in depth from the surface, and apparently not sufficiently large to admit a coffin. The sergeant and police-constable, 362, Yarnold, remained while the funeral service was performed by the clergyman, and when the coffin was about to be lowered it was discovered that the hole was not large enough to admit it; the gravedigger, in endeavouring to remedy this, removed a support, when a most disgusting scene presented itself, the adjoining grave giving way and filling the new-made one with bones and pieces of coffin.

"Subsequently the corpse was removed to a ground opposite, and there buried. Such is the state of St. Ann's burial-ground for the poor. Several persons present, being disgusted at the sickening sight, requested that the sergeant would report the occurrence to the authorities. A person named Wood, employed at the *Times*-office, informed the sergeant that he saw the grave-digger, whilst digging the grave spoken of, break up a coffin, from which A MOST ABOMINABLE SMELL AROSE, WITH A PICKAXE, thus desecrating the dead and endangering the health of all who inhale the horrid effluvium. A quantity of human bones were also rudely exposed to the gaze of the public in the burial-ground, the smell from which was intolerable. The following persons and several others are prepared to come forward, if required, to give evidence to the overcrowded state of St. Ann's (poor) grave-yard:—Henry Wood, the *Times*-office; Mr. Leach, 3, Broadway, Blackfriars; Mr. Eades, 7, Fleur-de-lis-court.

"C. SCOTT, Inspector."

It has been the practice severely to censure humble officials who perform the disgusting duties of digging through layers of human bodies to form new openings for the dead; but these are no more the parties to visit with censure than they are to remedy the defect. The source lies much higher, and requires a power of proportionate vigour. As one means to this end, we should be glad to see every incumbent of a parish connect himself with some sanitary association; for it is as much the duty of a Christian pastor to seek the temporal as the spiritual welfare of his flock. Whatever the clergy, however, may do, we hope the Government will speedily adopt measures for the abolition of burials in towns. The health and morals of society alike demand it.

TREATMENT OF CHOLERA.

AGAIN we return to the subject of Cholera; again we entreat those who have the power to investigate the various methods proposed for its treatment, to investigate those methods systematically, to trust the lives of those jeopardized to that in favour of which the most trustworthy evidence has been produced, and unhesitatingly to give their evidence for or against such treatment; and that not only by stating the general result, but by giving the details of the cases.

Let our readers clearly understand, that in order to arrive at anything like a correct conclusion in the matter, it is absolutely necessary for them to carry out the method of treatment, the value of which they are testing exactly in the way its advocates have advised. Cholera, in a large majority of cases, attacks those unaffected with chronic disease,—we refer our readers to Dr. Gairdner's paper in the *Monthly Journal*, for July, 1849,—is attended with nearly the same symptoms in all, and requires, consequently, but little modification in the treatment of individual cases; therefore it is that it offers peculiar facilities for testing the efficacy of any given treatment. There are only two modes of treating the disease which have in their favour any great amount of evidence. The success which the proposers of these methods of treatment declare they have obtained is so far greater than that stated to have resulted from any other method, that Dr. Stevens' saline and Dr. Ayre's calomel treatment claim attention with a voice so loud that they must be heard. Opium has failed in the treatment of collapse even in the hands of its warmest admirers—in the hands of those who yet unhesitatingly affirm it to be the sheet anchor. It is useless for the Board of Health longer to recommend its employment. To them are the lives of the community entrusted. Let them obtain the help of impartial judges, hear the advocates, the proposers of these methods of treatment, and call impartial witnesses. Dr. Stevens affirms, that he has evidence to show, that of 1000 cases of cholera, treated with the salines he used in Coldbath-fields Prison, not more than 6 per cent. have proved fatal. These cases consist of those treated by himself, and others under his direction, in Coldbath-fields Prison and at Greville-street Hospital; at St. Luke's Hospital, by Drs. Cambridge and Rance; at Bridewell, by Mr. Cox; at Abchurch-lane, by Mr. Tweedie. In private practice, by Mr. Whitmore, of Coldbath-fields-square; by Mr. Moss, of Windsor; Mr. Bossay, of Woolwich; Dr. Kendrick, of Warrington; and lately by Mr. Leckie, of Bonhill, Dumbartonshire. In addition to these cases, we have seen a letter from the Regent of Norway, in which he states, that the saline treatment of Dr. Stevens was very successful in that kingdom, and a paper issued by the Board of Health of Upsala, in Sweden, wherein it is stated to have been by far the most successful of any of the methods tried in that Kingdom. With this amount of evidence in its favour, Dr. Stevens has supplied us with the following statement of his method of treating the disease:—

"PREMONITORY SYMPTOMS.—Acting under the belief that the premonitory bowel complaint is an effort of nature to expel the poison from the blood and the body, on the first appearance of the premonitory symptoms, a seidlitz powder is to be administered; but if the patient experiences a sense of sinking without diarrhœa, more active saline purgatives must be employed. The aperient I have actually used is from one to three drachms of sulphate of magnesia, added to the seidlitz, and the whole taken in a state of effervescence: when this commences to act on the bowels, the patient is to be encouraged to drink freely of thin beef-tea, well seasoned with common salt. If vomiting is present, a sinapism is to be applied to the epigastrium: if the thirst is intense, seltzer, soda, or plain water, is to be allowed *ad libitum*.

"SECOND STAGE, OR THAT OF DEVELOPED CHOLERA.—The diagnostic symptoms being cramps,

coldness, or sinking prostration. The following powder,

"℞ sodæ sesquicarb., ℈j.; sodii chlorid, ʒj.; potassæ chloratis, gr. vii., misce.

is to be dissolved in half a tumbler of water, and administered in severe cases every half hour; in some malignant cases, every fifteen minutes; while in those cases which are not very severe, it is to be given every hour. The frequency with which the dose is to be repeated in each particular case varies according to its circumstances. In every instance, the saline must be continued until the circulation is fairly restored; when once that point is gained, the intervals between the doses may be lengthened; when re-action is completely established, it is to be left off by degrees. In extreme cases, the dose of the chloride of sodium is to be increased two drachms, and in some cases to even more than this. In those cases where the stomach is very irritable, a dilute solution of chloride of sodium is to be thrown up into the intestines; the temperature of this saline enema being as high as the patient can easily bear, which, as a general rule, is about 100 degrees Fahrenheit. When properly used, this is a means of great value.

"When the stomach is very irritable, the use of the saline powder may be occasionally suspended, and common effervescing mixtures, or small doses of the common soda powders, with an excess of the carbonates, used, until the vomiting abates, and then the carbonate of soda, with larger doses of the chlorate of potash, may be given without the chloride of sodium, or the chlorate of potash may be given by itself, in doses of ten grains each.

"A large mustard poultice is to be applied in such cases to the epigastric region, the moment the patient comes under treatment. When the saline powders are used at the time the stomach is very irritable, it is deemed advisable to dissolve them in a very small quantity of water.

"When cramps supervene, the extremities must be rubbed with hot flannel. The pain produced by the spasms in the muscles is not only relieved by the frictions, but by this, and the application of sinapisms to various parts of the body, the temperature is increased; an object of no trifling importance in the treatment of cholera. In this stage of the disease, as in the premonitory symptoms, seltzer, or cold water, may be allowed the patients, *ad libitum*. A strong infusion of green tea may also occasionally be used in severe cases with advantage.

"The patients must, invariably, be placed in a room, in which a large fire is kept day and night.

"The ejections, and all other impurities, must be removed immediately from the patient's room. No solid food must be allowed the patients for, at least, five days after their recovery from a state of collapse.

"In exceedingly malignant cases, or when the patient has not been seen till late in the disease, and especially where neither vomiting nor purging are present, the stage of collapse being well marked, more active measures must be adopted. An ounce of the chloride of sodium, with half a drachm of the chlorate of potash or the chloride of potassium, is immediately to be given in cold water, and repeated, if necessary, every half hour until the patient has taken about three doses of this strong solution. If re-action ensues, it is to be kept up by the common saline powders; and if the strong saline given by the mouth fails, as a last resource, a saline fluid must be injected either into the intestines or into the veins."

To the above Dr. Stevens has appended the following remarks, to which we earnestly call the attention of our readers:—

"In no case," says he, "left to my care was the smallest quantity of opium or other destructive agent administered, until after the cholera poison was evacuated from the system; above all, not in the early stage; for, from what I have seen, I consider this narcotic poison to be as fatal in cholera as it is in either African typhus, or the seasoning fever of the West Indies; and I would urge on those interested, that if they would test the efficacy of the saline treatment, they must have sufficient confidence to trust to it alone, for to poison with opium, or cajeput oil, or to exhaust his nervous system with galvanic shocks, to depress the vital powers with extreme cold, and then, because at the same time with these deleterious agents, salines have been administered, to declare the patient has fallen a victim to Cholera, while under the treatment recommended by me, is not only to offer a serious impediment to the spread of a most momentous truth, but to propagate a lie. For results obtained by such a mode of treatment I am not responsible, nor can I allow, without entering my most earnest protest, such cases to be admitted as evidence in determining the value of the non-purgative salines as remedial agents in the treatment of Cholera."

Will our readers favour us with the details of the cases treated by them in the way recommended by Dr. Stevens himself in the above communication?

THE OPERATIVE SURGERY OF JOHANN FRIEDRICH DIEFFENBACH.

Edited by
J. STEVENSON BUSHNAN, M.D.,
Fellow of the College of Physicians of Edinburgh;
And
ALEXANDER URE, Esq.,
Fellow of the College of Surgeons of England, and Surgeon to the Westminster General Dispensary, &c.

(Continued from page 125.)

CHAPTER IV.

THE APPLICATION OF LEECHES.

Applicatio Hirudinum.

The capillary bleeding effected by leeches is attended with irritation of the skin from the bites, and increased afflux of liquids to the part. The leech in common use is the Hirudo Medicinalis of Linnæus, (Hirudo Septentrionalis, Sanguisuga Savigny.)

The amount of blood drawn by a leech is very variable, and may be reckoned at from two drachms to an ounce. It does not depend so much on the size and activity of the annellid as upon the vascularity of the part. The number to be applied varies according to circumstances. Thus, while one may suffice for an infant, for an adult, assailed with violent inflammation, as many as fifty may be required. They are placed either on the part affected, in the vicinity, or some distance from it, according as a local or a derivative abstraction of blood is indicated; thus, for example, in chest affections upon the anus; in suppressed menstruation over the sacrum. Situations are to be avoided where the integument is hard, because the leeches do not take well, and little blood is procurable; as, also, where it is thin, and there is much loose cellular texture, because the bleeding is apt to be excessive, and followed by ecchymosis. When applied within cavities a speculum is needful; as, for instance, in the vagina. For the mouth a glass tube will suffice.

As to the manner of applying the leeches there is but little deserving attention. When there is plenty of space, we have merely to place them in an inverted glass or cylindrical wire gauze cage, over the part until they shall have fastened. But, if more precision is desired, the surface may be covered with a piece of moist gray bibulous paper perforated with small holes, through which the leeches are allowed to bite.

The after-bleeding is to be encouraged by repeated dabbing of a soft sponge wrung out of hot water, or of a warm dry cambric napkin. It may, in general, be arrested by a firm pad; otherwise we endeavour to compress the minute orifice, by means of the finger, with a bit of amadou, a dossil of lint, or, what is better, a tuft of cotton wadding dusted over with powder of gum, which forms a kind of paste with the blood; or lastly, lint imbued with powdered colophony and spirit of wine. The effusion of thin fluid gypsum is annoying to the patient, and tends, moreover, to form a hard plug in the wound, which is very teasing. There is usually no difficulty in stopping the bleeding in adults; not so with children. The hæmorrhage from a single puncture has proved fatal to an infant in the course of a night. To avert impending danger from this source, the edges of the leech-bite are to be transfixed with a fine insect-needle, round which a thick cotton thread is to be wound, as in the operation for hair-lip, and the ends cut off to prevent accidents. The puncture should not include more than the epidermis at the margin. The needle is allowed to remain till the second or third day, and then taken out with forceps, having been first of all loosened by a rotatory movement from the thread to which it is glued with dried blood.

The application of caustic, or a searing-iron, to check the bleeding, is prejudicial, as productive of pain, irritation, and an unseemly scar. In like manner, the forcible introduction of minute dossils of lint into the orifices is reprehensible, because they increase inflammation, and get readily beneath the skin. I once attended a lady for a large abscess of the neck, which formed four weeks after leeches had been applied. On making an incision, I discovered in its cavity a lump of macerated lint.

Where the leeches seem reluctant to leave hold, they may may be sprinkled over with common salt, either in substance or in solution.

CHAPTER V.

VENESECTION.

Venæsectio, phlebotomia.

Venesection is the act of opening a vein, and is usually performed with a lancet. The situations commonly selected for the purpose are, the bend of the arm, the back of the foot, and the neck. Besides the lancet, are required a woollen roller about two inches broad, and an ell and a half long, to bind round the limb betwixt the heart and the point of puncture, in order to produce repletion of the peripheral veins; a small square compress, and a linen or calico bandage a couple of inches broad, and from three to four ells in length. A graduated vessel is used for receiving the blood where great accuracy is required.

The sitting posture is favourable for patients that are not bed-ridden, the recumbent for such as are feeble and disposed to faint. It is, however, sometimes desirable to procure—as in attempting to reduce incarcerated hernia—syncope, in which case the patient ought to be set upright in bed.

At the bend of the elbow either of the following veins may be opened:—the cephalic vein, the basilic, the median, the median basilic, the median cephalic, the radial, the ulnar vein.

The puncture of the cephalic vein is attended with no collateral risk save that of pricking the musculo-cutaneous nerve; the vein itself, in fat persons, is very small, and the subjacent parts much raised, so that it yields comparatively little blood. The other veins are more prominent. The basilic vein lies for the most part over the artery, accompanied by the median cutaneous nerve and several lymphatic vessels. The median vein, the median basilic, and basilic, adjoin the brachial artery, and are separated only by the tendon of the biceps or the brachial aponeurosis; over the median vein are some twigs of the musculo-cutaneous nerve. The young beginner ought to choose for blood-letting either the cephalic vein, the median or basilic, near the internal condyle of the humerus, and to shun any spot in which arterial pulsation can be felt.

The patient being duly placed, his arm is to be brought into a horizontal position and somewhat bent. The surgeon carefully ascertains the situation of the artery. He then binds the roller with a couple of turns round the upper arm moderately tight, from two to three inches above the point selected for the puncture, and fastens it with a loop knot on the outside; hereupon the veins become turgid. The surgeon, standing on the outer side of the arm, seizes the blade betwixt the forefinger and thumb a few lines from its point, and lays the left thumb upon the vein so as to fix and distend it just below the point at which the lancet is to enter, the other fingers being behind and beneath the olecranon. He now rests the remaining fingers of the right hand upon the arm, inserts the lancet into the vein, and raises it with the point outwards. If the vein is small he makes a slant incision, if voluminous a longitudinal one.

After a sufficient quantity of blood has been abstracted, he places the thumb below the orifice to arrest the flow, slackens with the other hand the roller, cleans the surface with a moist sponge, puts the compress over the cut after bringing the edges together, and applies the bandage, which is made to encircle the arm above and below the elbow-joint, in form of the figure of 8. The last ought not to

be bound too tightly, lest it impede the reflux of blood; or lest too slack, lest serious hæmorrhage supervene.

VENESECTION IN THE FOOT.

The patient having previously taken a warm foot-bath, to favour distension of the veins, a roller is wound round the leg, between the calf and ankle. The surgeon then inserts a lancet into one of the swollen veins; the most eligible being the great saphena, just where it dips into the depression, betwixt the first cuneiform and the navicular bone. Where the integuments are thin, care must be had not to injure the aponeurotic textures. Should the blood run very scantily, the foot must be re-placed in a warm foot-bath, and the amount estimated from the red tinge imparted to the water.

VENESECTION IN THE NECK.

The vein which is opened in the neck is the external jugular, just as it proceeds over the sterno-cleido-mastoid muscle. This operation is most frequently resorted to in the instances of persons apparently dead, as from drowning, where prompt relief to the brain is demanded. In order to procure adequate venous distension, compression must be exercised upon both jugular veins simultaneously. An assistant compresses with his thumb the vein of the opposite side, and supports, at the same time, the head, which must be inclined laterally, in order to stretch the skin and vein of the side for operation. The patient being seated in an arm-chair, the surgeon fixes the vein above and below the point intended for puncture with the thumb and fore-finger of the left hand, and then makes the opening in a direction from above downwards, exactly in the longitudinal axis of the vein. The incision must be larger than in venesection at the arm, otherwise the blood will not flow freely, and is apt to be effused into the cellular texture. The most convenient vessel for receiving the blood is a common saucer. On no account should the opening be slanting or transverse, otherwise the wound may gape, and allow the ingress of air, which might cause death.

After the bleeding is at an end, the edges of the incision are to be carefully brought together, and retained in apposition by means of a strip of plaster carried round the neck. For additional security, two or three other strips of the length of the finger are to be laid across this at the centre, like the figure of a star. A compress is then superimposed, a band brought round the front of the neck, and the whole supported by an ordinary cravat, which fits better, and is less irksome than a roller.

ACCIDENTS WHICH MAY BEFALL DURING AND AFTER VENESECTION.

Injury of the Humeral Artery.—This is recognised by a pulsating stream of venous mixed with arterial blood. Greater certainty is obtained by finding an arterial jet on compressing the vein inferiorly, while on compressing the artery dark blood only issues. After the requisite amount of blood has been taken, the surgeon is to dilate the cutaneous incision, carefully cleanse the wound of clots (pressure being made meanwhile by an assistant upon the arteries and veins, both above and below), and then encircle the arm with narrow adhesive strips to ensure intimate union. A pad of lint soaked in starch-paste or white of egg, shaped like a walnut, is to be laid over, and maintained in its position by the application of a flannel roller two inches broad and four ells long, similarly imbued. When the hæmorrhage is considerable, the application of a tourniquet to the upper arm is sometimes needful to prevent the dressing being disturbed by the flow of blood. All prolonged compression of the artery on the upper side of the dressing is prejudicial. By following the above directions I have rarely witnessed the occurrence of aneurism in a recent case, and the wound has often healed in a few days in the most kindly manner. Should a false aneurism supervene, it must be treated in the usual way.

The entrance of air into a vein can happen only in blood-letting in the neck. It is accompanied by a roaring noise in the chest. Immediate copious venesection at the arm, and closure of the cervical wound, will alone save the patient.

Incision of a large cutaneous nerve is accompanied with a sudden pain like an electric dart through the limb, and often leaves behind a mixed feeling of uneasiness and numbness. Cold applications, leeches, and, subsequently, compression and oleaginous frictions, are frequently of service. Should these not suffice, the cicatrix may be cut across; and this failing, an incision of from a quarter to half an inch long may be made above and below it. This I have sometimes found successful.

The lymphatic vessels are occasionally injured in blood-letting. They appear as red streaks on the side of the arm. The pain extends to the axilla, and the glands in this situation are apt to swell. These, however, are not constant indications of an injury of this nature, but may simply denote sympathetic irritation. Tepid saturnine epithems are useful in the commencement.

Lesion of the tendons and fascia, inducing a painful inflammatory affection, seldom manifests itself till some days have elapsed. It demands an energetic antiphlogistic treatment.

Inflammation of the veins, as a sequel of venesection, when not the result of constitutional causes, depends on a dirty state, or breaking of the lancet. It either follows inflammation and suppuration of the external wound, or it assails the vein even when the outer wound looks healthy, and abides long after that is healed. The vein, in the instance of circumscribed inflammation, feels like a short firm cord, surrounded by doughy substance. From the aperture in the skin pus may be squeezed out. In other cases, the inflammation extends not merely to the veins, but to the other soft parts, especially the cellular texture, between the muscles, and secondarily to the skin. The extremity becomes enormously swollen, and of a bluish-red colour. The mischief spreads to the axilla, is associated with formation of pus in the venous trunks, advances to the heart, and proves fatal amid the typhoid febrile symptoms, characteristic of phlebitis. The treatment is of a general description: the topical means are arm-baths, poultices, leeches, and incisions into the integuments, to favour the evacuation of pus and of dead cellular texture.

REVIEWS.

Mooltan, a Series of Sketches during and after the Siege. By John Dunlop, M.D., Assistant-Surgeon of H.M.'s 32nd Regiment. London: Wm. S. Orr and Co.

We have great satisfaction in noticing this very beautiful volume by Dr. Dunlop, because it illustrates most forcibly the great advantage which Professional men enjoy, more especially when their duty leads them into foreign service, from having at their command the resources of a liberal and refined education.

The curricula of our Universities do not of course include the study of many collateral arts and sciences which delight the Professional man in his leisure hours, and cheer him in those solitudes to which, if in the public service, his duty must often call him; yet still the mind, refined by study, and cultivated by the academical course, derives pleasure from the sister arts, which never withhold their inspiration from their willing votaries. To be a good draftsman is important to every Medical man; but to excel as an artist rarely happens to men whose Professional education too frequently stifles those refined tastes which, in after life, often prove of such inestimable advantage.

It is gratifying to know, that to a Medical man we are indebted for some highly graphic sketches of the events that led to the siege and taking of Mooltan—the Badajoz of the East. The Work contains twenty-one plates—master-pieces of the tinted lithography of Mr. Maclure, certainly one of the first lithographers in England, and who, by the way, we think would be able to give the best effect to anatomical drawings. We have a view of the fort of Mooltan from the West; sketches of the inhabitants whose bold indifference to danger induced them to advance almost to the muzzles of our guns and fire into our embrasures; a view of the *eedgah* where poor Vans Agnew and Anderson were so barbarously murdered; portraits of the brothers of the Dewan Moolraj; sketches of Major Edwardes' troops, with whom he did the glorious deeds of which he so modestly wrote, "no Englishmen could consent to be beaten on the 18th June;" we see them in the trenches; before the walls, with their camp followers and their camel drivers. Then we have the raising and re-commencement of the siege; the storming of the "*Mundee Awa*," or great mound, that dashing achievement so lucidly detailed in the official despatch by Brigadier Capon; the breaching of the Delhi gate and the explosion of the magazine with its 16,000 lbs. of gunpowder, that sublimely awful sight "which shook the earth for miles, and for hours darkened the atmosphere by a dense cloud, which hung like a mantle over the city;" then the fort after this great catastrophe, its side "marked by a long deep pit, around which buildings are piled on buildings, and scarcely one brick remains on another; where corpses, carcases of animals, and every description of property strewed the ground;" and where, with all the characteristic indifference of the people, Moolraj, when formally summoned by General Whish to surrender, "rammed the letter down his longest gun, and fired it back." The storming of the Knoonee Boorj Breach, the struggle in the town, the capture of the standards, Mooltan after its capture, and the breaching of the walls of its fortress are admirably delineated, and show the force and power of lithography and the skill of Mr. Maclure in a surprising manner. Next, we have the surrender of Moolraj himself, the last to pass through the gate of the fortress he had so long and bravely defended. "He was gorgeously attired in silks and splendid arms; he looked round without the smallest emotion, and showed in his countenance neither defiance nor dejection; but moved along under the general gaze, like a man conscious of deserving the admiration of even his enemies, for having done his duty to the last."

The "last scene of all that ends this strange eventful history" is the funeral of Vans Agnew and Anderson—an affecting and appropriate close of the historic tragedy of which their murder was the origin; and now "a battered mass of ruined fortifications, and a deserted city, is all that is left to tell of the Mooltan rebellion."

We have lingered perhaps longer over this splendid volume than becomes a Medical journalist; but if apology be needed, it will be found in the fact that its Author is of ourselves—a Medical man,—that he has done honour to our Profession. We rejoice to find a Work exhibiting so much literary and artistic skill emanating from a Professional pen. Its composition must have relieved the tedium of many a leisure hour in a foreign land—so may its perusal by our Professional brethren at home afford them many an interval of agreeable recreation, and above all inspire the young aspirant to cultivate the delightful and highly useful art of design.

Whether on the library or drawing-room table, it is a beautiful volume, and has our hearty recommendation.

Letters on the Truths contained in Popular Superstitions. By Herbert Mayo, M.D. Frankfort: Sauerlænder. Edinburgh: Blackwood.

The superstitions which chequer the horizon of the human mind in different ages, and which sometimes foreshadow the revelation of important scientific truths, ought not to be regarded as the mere hazy emanations of a disturbed imagination imposing on the credulity of the multitude. We may rest assured, that no faith, however apparently absurd, ever took a strong hold of the public mind without being founded in some fixed principles in nature. The duty, therefore, of the philosopher, is rather to watch with curious interest, than to turn away with ridicule and distrust,—for, as there can be no effect in the physical world without some fixed cause, so no belief will attain popularity without some cause for its prevalence. The law of sensorial illusions has explained away

the mysteries of second-sight, ghosts, and dreams the phenomena of mesmerism,—insensibility,—convulsions, — mesmeric coma, — sleep-talking,—explain satisfactorily the whole history of witchcraft and imputed demoniacal possession; hence, a science progresses, new light is thrown upon the shadowy forms of almost all popular delusions, until scarcely a marvel remains unraveled in the temple of Mystery. Our accomplished friend, Dr. Herbert Mayo, has therefore imposed upon himself a pleasant task,—upon the "banks of the romantic Rhine," at his agreeable retreat at Boppart, where we should imagine he is in the very "thick of the witch element;" and from whence we hope to receive many contributions to our Journal. He has, it appears, been walking about with the divining-rod in his hand, holding communion with ghosts and vampires until the twin-castles above his wizard residence, the Sternberg and Leibstein, must have been shaken to their foundation; he has, like another Manfred, dived into "the caves of death," propounding the nature of the trance which overcame Arnod Paole in the cemetery of Meduegna, and Timarchus, in the cave of Trophonius; and, having solved many other problems, which appear to float between this world and the next, and which might have startled a more timid spirit, he has sat him down in the solitary winter evenings by his red stove-side, and, with his magic pen, has traced, in letters to a friend in England, these mystical effects to their more mystical causes. He has thus, without the aid of Mephistopheles, whose name does not appear in a single letter, sat down like a philosopher; and has endeavoured, with patience and perseverance, to sift the grain from the chaff, the ore from the dross, and determine what are the truths contained in popular superstitions.

"There must be a real foundation," observes our Author, "for the belief of ages; there can be no prevalent delusion without a corresponding truth; the visionary promises of alchemy foreshadowed the solid performances of modern chemistry, as the debased worship of the Egyptians implied the existence of a proper object of worship."

True; but to a certain extent only: the crucible of the alchemist developed the existence of certain hitherto unknown metals; but the process was as practically analytical as any now adopted in our chemical laboratories. Not so, however, with a class of superstitions which are purely imaginary, the elements of which escape any mode of palpable demonstration. The vampire tradition, for example, appears to be a pure fiction; but our Author apparently thinks not, and has translated several stories of the kind from the German, which are obviously absurd and incredible. Nevertheless, as, according to his belief, there must be a certain amount of truth in every delusion, so Dr. Mayo hits upon the following explanatory hypothesis, viz.:—

"That the bodies found in the so-called vampire state, instead of being in a new or mystical condition, were simply alive in the common way, or had been so for some time subsequent to their interment, —that, in short, they were the bodies of persons who had been buried alive, and whose life, where it yet lingered, was finally extinguished through the ignorance and barbarity of those who disinterred them."

This hypothesis, however, only applies to the appearance of the body of the supposed vampire, and does not, in any respect, account for the very marvellous stories which are related of the persons bitten by them. In accounting for the appearance of ghosts, Dr. Mayo, we believe, is quite right in ascribing their supposed appearance to sensorial illusions; but we are scarcely prepared to admit his psychological explanation:—

"I shall assume it to be proved," he observes, "that the mind or soul of one human being can be brought in the natural course of things and under physiological laws hereafter to be determined, into immediate relation with the mind of another living person. If this principle be admitted, it is adequate to explain all the puzzling phenomena of real ghosts and of true dreams; for example, the ghostly and intersomnial communications with which we have, as yet, dealt have been announcements of the deaths of absent parties. Suppose our new principle brought into play—the soul of the dying person is to be supposed to have come into direct communication with the mind of his friend, with the effect of suggesting his present condition. If the seer be dreaming, the suggestion shapes a corresponding dream; if he be awake, it originates a sensorial illusion. To speak figuratively—*merely figuratively*—I will suppose that the death of a human being throws a sort of gleam through the spiritual world, which may now and then touch with light some fittingly disposed object, or even two simultaneously, if chance have placed them in the right relation, as the twin spires of a cathedral may be momentarily illuminated by some far-off flash, which does not break the gloom of the roofs below. The same principle is applicable to the explanation of the vampire visit. The soul of the buried man is supposed to be brought into communication with his friend's mind—thence follows as a sensorial illusion the apparition of the buried man. Perhaps the visit may have been an instinctive effort to draw the attention of his friend to his living grave."

All this proceeds upon the assumption of the cognate soul possessing the power of an intermediary communication between the dead and the living, and would doubtless explain many wonderful stories; but we are incredulous mortals, and in the faculty of invention find an easier solution of the mystery. Nevertheless, it is pleasant, in a poetical sense, to weave subtile theories like these; and thus we too have often amused ourselves on the banks of the Rhine.

As might be anticipated, the Author devotes one of his Letters to Mesmerism, upon the principles of which he might, had it occurred to him, have attempted the solution of many mysteries, such as second sight, trance, somnambulism, prevision, &c. Indeed, we are somewhat surprised, that he has omitted to notice the curious identity which appears to exist between the phenomena of mesmerism and the signs of witchcraft and demoniacal possession, as exhibited in the darker ages. There can be no doubt that nervous symptoms, insensibility, convulsions, ecstasy, &c., were developed in many of those cases; and these effects appearing to be supernatural, caused the unhappy creatures to be led to the scaffold or the stake. "No person," says the venerable Baxter, "was more backward to condemn a witch, without full evidence, than Judge Hale;" and Reginald Scott truly observed, "Many of these poor creatures had more neede to be relieved than chastised; and more mete were a preacher to admonish them, than a jailor to keep them; and a physician more necessary to helpe them, than an executioner or tormentor to hang or burn them." From the works of Joseph Glanvil, Henry More, Increase Mather, Reginald Scot, Hutchinson, and other writers upon witchcraft, a number of curious facts might be collected which would show that there is nothing whatever of novelty in the phenomena produced by mesmerism. But we must now close our notice of this little volume, which we recommend to the attention of our readers. It is written in a philosophical spirit, and will amuse all who feel disposed to peep occasionally into the world of wonders.

CHOLERA IN DUMFRIES.

[To the Editor of the Medical Times.]

SIR,—In the *Medical Times* of Saturday last, I observed, to my no small amusement and surprise, a letter from Mr. James Smyth, of Dromore-house, Coleraine, in which he claims to having *first* called my attention to the sensation, somewhat resembling an electric shock, experienced when in contact with a cholera patient. Had this been so, I could, and very naturally would, have told my young friend, that the peculiar phenomena alluded to had been recognized and described by me upwards of sixteen years before I had the pleasure of Mr. Smyth's acquaintance—before, I dare say, he had "entered upon his teens," certainly long before he could have been called upon to attend a cholera patient. In 1832, when epidemic cholera first appeared in this town, I had, in conjunction with my excellent friend, Dr. Bell, the medical superintendence of the Cholera Hospital. In December of the same year, I drew up a Report of the Cholera Hospital, which was transmitted to, and duly acknowledged by the then Board of Health in London. In that Report I mentioned the peculiar thrilling sensation above referred to as having been observed by me, and subsequently by others during the prevalence of the epidemic. To adduce further proof of the impotency of Mr. Smyth's claims would be, to "throw water on a drowned rat." Trusting, therefore, for Mr. Smyth's credit, that he may be more happy in his next *discovery*, and that no rude hand like mine will be stretched forth to snatch it from him,

I am, Sir, your obedient servant,

JAMES GRIEVE, M.D.

Buccleuch-street, Dumfries, Aug. 28th, 1849.

[To the Editor of the Medical Times.]

SIR,—My attention has been attracted to a Communication that appeared in your Paper, No. 517, of the 25th August, signed by Mr. James Smyth, Dromore-house, Coleraine, and announcing a claim of priority in observing a peculiar sensation imparted by the skin of persons labouring under cholera, and in the last stage of the disease. I feel it to be an act of duty to my colleague, Dr. Grieve, who is, and has long been, one of the Physicians to the Dumfries and Galloway Infirmary, to state thus publicly that he has repeatedly described to me the phenomenon alluded to—the thrilling or tingling nature of the impressions communicated, detailing the original discovery, and the circumstances under which it was made, many years previous to the second invasion of cholera, and I should conceive long before the professional sudies of my young friend, Mr. Smythe, had even commenced. I am likewise aware that Dr. Grieve has recorded this singular fact in his report of his experience of cholera in Dumfries in 1832.

It is not my intention to estimate the value of the observation, the influence which it may exercise upon the theories as to the cause, or nature, or propagation of cholera, or the connexion which it may be found to have with cognate phenomena, or with those noticed by Sir H. Marsh, &c.; but it is just and necessary, that, in all investigations upon the subject, the merit of the original observation, if merit there be, should be secured to its true author, Dr. Grieve.

I am Sir, your obedient servant,

W. A. F. BROWNE, M.D.,

Crichton Institution for Insane, Dumfries.

27th August, 1849.

[When we inserted Mr. Smyth's letter upon this subject, we expressed our conviction, that other Medical men in Dumfries had long since observed the "thrilling sensation" which he appears to fancy he had the merit of discovering;—and the above communication from Dr. W. A. F. Browne, whom we esteem as a high authority in all matters relating to Medical science, fully confirms our own conviction upon the subject. Were any evidence wanting to prove the non-originality of Mr. Smyth's observation, it would be irrefragably supplied by the following extract, alluded to by Dr. Browne, which we have taken from Dr. Grieve's Report of the Dumfries Cholera Hospital, dated, "Dumfries, Dec. 3, 1832."

"There is a circumstance," says Dr. Grieve, which, so far as I know, has not been mentioned by any writer on cholera, namely, a peculiar benumbing, or tingling sensation, exactly similar to a slight galvanic shock, felt on applying the hand to the skin of a cholera patient when in the collapsed stage, and more particularly when the body is bedewed with a cold and clammy sweat,—which extends from the extremities of the fingers to the elbow, and sometimes even to the shoulder; occasionally the impression is so powerful as to deprive the arm, for a few seconds, of sensation and motion; whether or not this peculiarity depends on some extraordinary state of the nervous system I cannot take upon myself to determine. It may not be uninteresting, however, to state, that not a single individual afflicted with paralysis, partial or confirmed, has been attacked with cholera."

To the above Dr. Grieve, moreover, adds in a note, "The same sensation was experienced by several Practitioners of the town."

We very often find that the ignorance of men upon what may be described as the literature of the Profession, gives a tone of self-importance to observations which have long since been made, but which, not being known to them, are supposed to be original. We, therefore, in a spirit of the utmost good nature, recommend Mr. Smyth in future to make himself a little acquainted with the history of such discoveries, as he may hereafter have the good fortune to make, before he arrogates to himself a merit which may have already been conceded to another.—ED. *Medical Times*.]

OXYDE OF SILVER IN CHOLERA.

[To the Editor of the Medical Times.]

SIR,—I am not aware, whether, amongst the numerous remedies that have been used in cholera,

any member of the Profession has recommended oxyde of silver; but, reasoning from its powers in checking uterine discharges, &c., I have, for the last few weeks, been ordering it in numerous cases of diarrhœa, accompanied with vomiting, in doses of one quarter of a grain every third hour, or oftener, until the purging subsides; and I may say, in most instances, found it eminently successful. This town (as I attribute it) from our excellent sanitary regulations for the last few years is extremely healthy, and free from cholera; and, I have, therefore, had no opportunity of testing the oxyde of silver in that deadly disease; but, through the medium of your Journal, I would call the attention of Medical Men practising in districts where the cholera exists, to give it a fair trial.

I am, Sir, your obedient servant,

Wm. Philpot Brookes, M.D., &c., &c.

Albion-house, Cheltenham, Aug. 14, 1849.

[The use of the oxyde of silver has been strongly recommended by Sir James Eyre and others in the treatment of dysentery and diarrhœa.

Pills of the nitrate of silver, in doses of from 1 to 2 and 3 grains every hour, combined with ¼ grain of opium, have been extensively employed by Mr. Ross. We expect shortly to be able to lay these cases before the public.—Ed. *Medical Times.*]

CASE OF SUBCUTANEOUS PARASITE.

[To the Editor of the Medical Times.]

Sir,—I send you the history of the following case:—

A—— M'L——, aged 13 years, a stout, healthy boy, complained, in May, 1848, of pain in the right side of abdomen, at first situated in the iliac region, but latterly extending as high as the hypochondriac region. He was troubled with this pain during the following six months, occurring at intervals with great severity I saw him, for the first time, in December of the same year; he did not then complain of pain, but of a feeling in the left side, as if worms were crawling under his skin; at the same time stating that several pimples had appeared where he felt the sensation, with a small aperture in the apex, through which a white sharp point was protruded resembling the head of a worm, and instantly retracted, as if the aperture were too narrow to allow the remainder of the body to follow. On examination, nothing abnormal was seen. He was ordered some simple medicine, and desired to let me know when one of these pimples occurred again. The next time I saw him, —about a month afterwards,—one of these pimples was situated within the areola of left breast, looking very like a small-pox pustule, with an aperture instead of a depression in its centre, at the bottom of which was seen the head of a white insect, slightly protruded and retracted. The boy mentioned, that since December a similar pimple had appeared on the back between the shoulders, and one on the top of left shoulder, plainly indicating that the insect, or whatever it was, had burrowed its way from the right hypochondriac region to the left breast by the back of the body. He was almost distracted, tossing and rolling himself in bed, not from bodily pain, but the idea that his skin was infested with worms. A small incision being made over the apex of the pimple, and pressure made round with the fingers, an insect, like a caterpillar, crawled out, and crept on an adjoining table for some time. Till put in spirits it was about an inch and a quarter long, as thick as a crow's quill, with six or eight feet on each side, the head sharp pointed, and the whole of a white colour. Since, the boy has complained of no uneasiness.

How was this insect introduced under the skin? Was the ovum, from which it was produced, deposited in the first place under the skin, or introduced into the alimentary canal, and matured there, then burrowing a passage through the various textures to the skin, which, from its greater toughness, it could not penetrate? This last is my own opinion, formed from the circumstance, that when attending school he was accustomed to eat his bread at the side of a spring, and having no vessel to drink out of, he drank out of the spring, when doing so he must have imbibed the ovum, from which the insect was produced. The facts may be relied on. I have heard of another similar case, where the insect came out in the thigh.

I should like to know if such cases are common, as I seldom see them mentioned in any publication?

I am, Sir, yours obediently,

A Young Country Practitioner.

Argyleshire.

[The analogous cases of subcutaneous parasitic larvæ are much more frequent in the lower animals than in man: as, *e. g.*, the *Œstrus Bovis*, or larva of the Gadfly, the ovum of which is deposited by the parent insect by a sharp instrument or ovipositor, which pierces the thick cuticle. More than one instance has, however, been recorded of larvæ, resembling that of the Œstrus, having been similarly developed beneath the human integument. The late Mr. Howship communicated a case of this kind to the Royal Society, the particulars of which, with a figure of the larva, which he called "*Œstrus Humanus*," will be found in the "Philosophical Transactions." In all these instances the ovum, which is afterwards developed into the parasite, is introduced from without, and the artificial clothing may account for the extreme rarity of such cases in our species.

As to the circumstance alluded to by our Correspondent, of this young patient drinking out of the spring, that is not so rare as the occurrence of a subcutaneous parasitic larva. We should like to see the country schoolboy who had not resorted to that primitive mode of quenching his thirst! We know of no larva of an insect with an organisation equal to tunnelling through the tissues from an internal mucous canal to the external tegument. The information of chief value in the present case would be the specific characters of the parasite in question; and the present communication, which afforded our young Correspondent a rare opportunity of making a welcome addition to helminthic pathology shows how much has been lost to him by the want of that elementary instruction in zoology which is afforded to the analogous class of Practitioners on the Continent. As a sharpener of the powers and habits of observation, its value cannot be overrated in the preparatory education of a medical man. One lecture on entomology would have rendered it impossible for an attentive listener to have had so rare an opportunity of examining a human subcutaneous larva and not to have determined the number of its segments, or "whether it had six or eight feet on each side."—Ed. *Medical Times.*]

OFFICIAL RETURNS—CHOLERA.

[To the Editor of the Medical Times.]

Sir,—I shall feel obliged if you, or any of your correspondents who have the opportunity, will verify the official returns that are daily issued of the number of deaths from cholera, as I have reason to believe that the cases entered in columns one and two, which relate to diarrhœa and rice-water evacuations, are often carried into the total column, thus presenting a most fallacious return, and causing unnecessary alarm. At the same time, I would observe that these official returns require so much care in filling up, that it is no wonder Medical men, in the midst of their necessarily increased practice, should fall into this error.

A Layman.

SOUTH LONDON MEDICAL SOCIETY.

The Adjourned Meeting of this Society was held on Thursday evening last, at the Literary and Scientific Institution, Borough-road, for the further discussion of the nature and treatment of the prevailing epidemic.

J. Hilton, Esq., President.

We are sorry that the nature of the discussion precludes our stating anything more satisfactory than we were obliged to do on the former occasion. Not that the gentlemen came unprepared to speak of that concerning which they had but little experience; but simply from the fact that, despite the very large experience of some, and the strenuous endeavours of all to combat the disease, it still continued to baffle their efforts. No Professional man, unfortunately, could leave the meeting, and say, "I am now better prepared to treat the disease." From opium to wet-blankets, from cayenne pepper inwardly to hot applications outwardly, all had been successful, and all had failed. As to contagion—with some it was decidedly contagious, with others as decidedly non-contagious; by one it was considered to arise from malaria, from bad water, bad sewerage, or other local causes; by others all these causes were repudiated; the contagionists brought facts to prove their position; the *nons.* also appealing to facts to prove theirs. Still, this one point is certain, that, whatever the conclusions as to the nature of cholera, or the causes which lead to it, if but a tithe of what was stated of the sanitary condition of some districts be true, (and we cannot impugn it,) the Profession, in the absence of a specific for cholera, must assume the position of a Preventive Body, and endeavour to preserve health where they confess they cannot cure disease. There may be some few who attach no importance to open drains, to bad water, and to fetid exhalations, as being productive of this disease; but if these have no influence, we might be inclined to ask why our olfactories scent them, or why, if Smithfield air be so beneficial, the atmosphere of our earth is not impregnated, as a rule, with its various odours.

On the whole, we fear that, in the present state of the question, science would hardly be advanced by our entering more largely into the discussion at the meeting; we believe it will be better—far better —for the Profession and the public, that Dr. Gull's recommendation should be acted on, and which accords with the opinion expressed by us last week, viz., for each Practitioner to gather up, statistically, the facts of his cases, giving the symptoms when he was called in, the stage of the disease, the age of patient, the locality, the treatment, and the results. When these returns shall be collected, classified, and compared, we may hope (at least) to learn something; and, if still a specific remains undiscovered, we shall at least have learned to discard those modes of treatment which appear to have been worse than useless.

It was the intention that a division should have been taken in the meeting on the question of contagion; but, on consideration, it was thought expedient not to do so, because of the influence it might have, if answered affirmatively.

MEDICAL NEWS.

Apothecaries' Hall.—Names of gentlemen who passed their examination in the science and practice of medicine, and received Certificates to practise, on Thursday, August 23, 1849:—Benjamin Webster, Morley-lodge, Leeds; Rawson Senior, Batley, near Dewsbury, York; John Earnshaw, Clitheroe, Lancashire; George Burnham, Great Grimsby.

Royal Infirmary for Children.—Dr. S. Wm. J. Merriman has been this day elected one of Physicians to the Royal Infirmary for Children.

Obituary.—On the 18th inst., at 22, Charlotte-street, Leith, Walter Bruce, Esq., M.D.—On the 21st inst., at 14, Clerk-street, Edinburgh, Dr. George Wigton.—On the 24th inst., aged 53, Dr. John Udny, M.D., Surgeon, Superintendent of the Cholera Hospital, Toxteth-park.—On the 25th inst., at Glasgow, William Crawford, Esq., M.D., late of Port-Glasgow.

War Office, August 28.—21st Regiment of Foot—Acting Assist.-Surg. Andrew Edge to be Assist.-Surg., vice Summers, promoted in the 3rd West India Regiment. 36th Foot—Surg. George Douglas Dods, M.D., from 3rd West India Regiment, to be Surg., vice Russell, deceased. 3rd West India Regiment—Assist.-Surg. John Summers, M.D., from 21st Foot, to be Surg., vice Dods, appointed to the 36th Foot.

The Cholera.—The returns from the provinces, in reference to the progress of the cholera, are anything but satisfactory. At Bristol, the disease has been on the increase. It has appeared at Liverpool, Oxford, and in some villages which were not visited in 1832. The deaths, in proportion to the attacks, continue also to be very great. In the week ending Saturday, August 25, the deaths, in London, were 2457; of which 1276 were by cholera, 238 by diarrhœa. The deaths from all causes, in each of the last seven weeks, were 1070, 1369, 1741, 1931, 1967, 1909, 2229, 2457; the deaths from cholera, 152, 339, 678, 783, 926, 823, 1229, and 1276. Although the number of deaths, last week, is greater than any number yet recorded, it is gratifying to learn that active measures are now in

actual operation, or commencing, in every district, to combat the great epidemic which has already destroyed 7470 lives in London. The mortality stands in favourable contrast to that which has been felt in other cities, where the visitation has recalled the ravages of the middle ages. But, if the general sanitary state and arrangements are superior to those of the other civilized countries of Europe, it is quite certain that, while the present epidemic has excited some talk and terror, the efforts which have hitherto been employed to combat it look feeble and insignificant when contrasted with the vast means and agency which are brought to bear by the nation in other fields for the protection of life and property. The energy with which parts of our institutions work makes the defects of the rest more evident. On August 9th last, a man was murdered in Bermondsey, and before his death, reported by the Coroner, will appear in these returns, one, and it is probable both the persons charged with the murder will be in custody. Steam-ships, the electric telegraph, the heads of the police, and professional agents, specially chosen, were all employed to arrest the destroyers of this life; the columns of the newspapers were filled with the details of the death. On the same day (August 9) a stock-broker died at No. 12, Albion-terrace, Wandsworth-road; a widow lady, and an old domestic servant at No. 6; in the five preceding days in the same terrace the daughter of a grocer, a child of five years of age, had died at No. 1; the widow of a coach proprietor and a commercial clerk, at No. 2; a gentleman's widow at No. 3; a surgeon's daughter at No. 4; a spinster of 41 at No. 5; the wife of a Dissenting minister, his mother, a widow lady, and a a servant at No. 6; a young woman of 21 at No. 10; a gentleman at No. 12, where the stock-broker died; a commercial clerk and a young woman of 19, at No. 13, where a young woman also died on July 28; a gentleman's wife at No. 14, who had seen her daughter die there the day before. The 19 persons died of cholera; many of the inhabitants of the terrace were dispersed; and the deaths of several have been registered elsewhere. "It appears," says the registrar, Mr. Frost, that at No. 13, inhabited by Mr. Biddle, where the first death occurred, and where two deaths were afterwards registered, the refuse of the house had been allowed to accumulate in one of the vaults (which is a very large one) for about two years, and, when removed last week, the stench was almost intolerable, there being about two feet of wet soil filled with maggots. The drains, also, had burst, overflowed into the tank, and impregnated the water with which the houses were supplied. On the back ground, in the distance, was an open ditch, into which nearly the whole of the soil of Clapham runs." As turpentine to flames, so is the exhalation of such cellars, tanks, and sewers to cholera; it diffused itself rapidly, attacked many, and 19 inhabitants, after some hours of suffering, sickness, and spasms, expired. The effects of decomposing refuse and water on health were well known—their fatal subsidies to cholera had been heard of every day; yet no steps had been taken for their removal from Albion-terrace in July, no medical police had interfered to disturb the contents of Mr. Biddle's cellar; and now the nineteen masters, servants, parents, children, rest in their graves, it appears to be taken for granted, that blame attaches to nobody—to nothing—to the householders themselves—to the guardians of the district—to the institutions of the country! Such mean intangible instruments of death can be invested with no dramatic interest; but fixing our eyes on the victims, it is well worth considering whether substantially it is not as much a part of the sound policy of the country that lives like those in Albion-terrace should be saved, as that the murderers of the man in Bermondsey should be hanged. The revelations of the state of their districts in the Registrars' notes of this and last week prove that it will be no easy task—I say, not to stay the plague of cholera, for it will subside—but to remove the evils which make cholera and all epidemics fatal. The vast task of the physical amelioration of the population demands the energies of the best men in Her Majesty's dominions. When, in the country from which Asiatic cholera came, our armies seemed for a moment worsted, and the empire threatened, the great captain of the age is reported to have addressed to another the memorable words, "If you do not go, I must." That enemy was distant. We have one very near, in our streets, of which cholera, a servile minister, has destroyed already 7470 lives in London, and thousands more in the rest of the kingdom. Who will go out against this enemy? Is it too powerful or too feeble for the arm of the greatest? Will no glory crown its conquest? Is the country insensible to its magnitude? Will not all the national strength and resources be put forth to improve the hygienic condition of the people, and to rid England of the causes of the fatality of epidemics? This may yet be done by the Government, aided by the force of facts and of enlightened public opinion.

British Homœopathic Association.—A meeting of this Association, of which the Duke of Beaufort and the Marquess of Anglesey are President and Vice-president, was held on Wednesday evening, August 20, at Willis's Rooms. The Report stated the number of members to be 1270, and also that 1300 volumes and 11,000 pamphlets on homœopathy had been distributed by the Association during the current year. After an Address from the Chairman, Mr. Sampson, followed by speeches from Captain Warde, R.A., the Hon. Augustine Moreton, Thomas Uwins, R.A., Drs. Quin, Chapman, and others, a resolution was carried for the immediate establishment of a London Homœopathic Hospital.

MORTALITY TABLE,

(Metropolis.)

For the Week ending Saturday, Aug. 25, 1849

Causes of Death.	Total.	Average of Five Summers.
All Causes	2457	1008
Specified Causes	2433	1005
Zymotic (or Epidemic, Endemic, and Contagious) Diseases	1714	302
Sporadic Diseases:		
Dropsy, Cancer and other Diseases of uncertain or variable seat	52	44
Tubercular Diseases	182	190
Diseases of the brain, Spinal Marrow, Nerves, and Senses	108	119
Diseases of the Heart and Blood-vessels	32	29
Diseases of the Lungs, and of the other Organs of Respiration	93	81
Diseases of the Stomach, Liver, and other Organs of Digestion	77	76
Diseases of the Kidneys, &c.	8	11
Childbirth, Diseases of the Uterus, &c.	10	7
Rheumatism, Diseases of the Bones, Joints, &c.	4	7
Diseases of the Skin, Cellular Tissue, &c.	...	2
Malformations	7	3
Premature Birth and Debility	31	22
Atrophy	37	[illegible]
Age	48	43
Sudden	8	8
Violence, Privation, Cold, and Intemperance	39	36
Causes not Specified	4	3

The following is the number of Deaths occurring from some of the more important special causes:—

Apoplexy.		Heart	29	Phthisis	123
Bronchitis		Hooping-cough	29	Pneumonia ..	40
Cholera.........	1276	Hydrocephalus	31	Scarlatina	18
Childbirth	6	Influenza	?	Small-pox	6
Convulsions...	39	Liver	13	Stomach	4
Diarrhœa......	238	Lungs...........	6	Teething	15
Dropsy	17	Measles	16	Typhus	77
Erysipelas ...	9	Paralysis	19	Uterus	2

BIRTHS AND DEATHS.

	Births.	Deaths.	Deaths over Births.
Males ...	664	1172	508
Females	653	1285	632
Total......	1317	2457	1140

METEOROLOGY OF THE WEEK.

	Mean of Barometer.	Mean of Thermometer. Dry.	Ditto. Dew Point.	Difference between the Mean Temperature of the day and the same day on an average of 7 years.	General Direction of Wind. A.M.	General Direction of Wind. P.M.	Amount of Horizontal Movement of the Air.	Rain in Inches.	Electricity*

TO CORRESPONDENTS.

"Hermes."—*Post-mortem* digestion of the stomach is of frequent occurrence, especially in those who have suddenly died. Hunter first observed this phenomenon in a man who had his skull fractured shortly after he had eaten a hearty supper. On opening the abdomen, he found the stomach dissolved at its great end, and a large portion of its contents had escaped. Subsequent experiments have shown that the gastric juice after death exerts a powerful influence on the coats of the stomach.

"Anglican."—1. The license of the King and Queen's College of Physicians in Ireland is equivalent to a medical degree. 2. The Fellows are chosen from the Licentiates of three years' standing. They are required to have taken the degree of M.D. in one of the Universities of Dublin, Oxford, or Cambridge; or to have taken the degree of A.B. in one of these Universities, and to have received the medical education requisite for obtaining the license. These qualifications may be dispensed with when the number of Fellows is reduced to six.

"G. B., M.D."—We are not aware that any one has discovered the real nature of the semi-transparent structure referred to; it was, however, first observed by Breschet.

"Senex."—We can offer no opinion, as we have not yet seen the new Medical Bill.

"L."—The predisposition to general paralysis varies with the age.

"Civis."—(1) It does not follow that because there is one hole only produced by a ball, that it is therefore lodged. It may escape by the same place at which it entered. (2) A ball may split by striking against a sharp edge of bone.

"Juvenis."—(1) A pulsating erectile tumour is sometimes difficult to distinguish from aneurism. (2) A ligature might be useful.

"J. T."—Nitric Acid has been strongly recommended, and is worthy of a trial.

"A Surgeon."—The forceps is generally employed by dentists for the extraction of teeth. Several sets are used.

"Rus."—"Ramollissement" may result from an injury received many years previously. The symptoms are obscure.

"R.R.C."—We think the long straight splint.

"Querist."—A simple fracture may be attended with a wound; but unless the wound communicate with the fracture, it is not compound.

"M.D."—An extract for medical use ought to contain, if the active constituents of the substance from

"Edward, Liverpool."—The specific gravity bottle affords very accurate means of determining the comparative densities of liquids. It generally consists of a globular bottle, with a flat bottom and a slender neck, which holds exactly 1000 grains of distilled water at a certain fixed temperature.

"Pharmacopœia."—Mucilage answers better than an alkali for making an emulsion with castor-oil or copaiba; but the alkali forms the best emulsion with oil of almonds.

"Studens."—Specific gravity beads are hollow sealed globes of glass. Each bead is a small hydrometer, intended to indicate one fixed density, by its remaining half way between the top and bottom of the liquid into which it is introduced. The beads, we think, are sold in sets, each one being marked with the specific gravity it is to indicate at a certain fixed temperature.

"Jus."—It is possible for a person to receive a fatal blow without ecchymosis being produced in the part struck.

"———."—Ship fever is, no doubt, often produced by a foul state of the hold of a vessel. It by no means follows, however, that because a ship has a foul hold that she will necessarily be unhealthy; still, there are so many instances where this has been the case, that the converse may be considered the exception to the rule. In the Eclair, which was supposed to be perfectly clean, there was afterwards found a large collection of mud three inches deep.

"J. M., Gosport."—1. Chlorine possesses no acid properties. It has not a sour taste; does not redden the blue colour of plants; and shows comparatively little disposition to unite with alkalies. 2. The most convenient method of preparing it is by mixing concentrated hydro-chloric acid, contained in a glass flask, with half its weight of finely-powdered per-oxide of manganese. It should be collected by displacement of air in dry bottles.

"Galen."—Water, when it passes into ice, ceases to conduct an electric current.

"Mr. H. H. Muggeridge, Reading."—Received.

ORIGINAL LECTURES.

HUNTERIAN LECTURES.

ON THE

GENERATION AND DEVELOPMENT OF THE INVERTEBRATED ANIMALS.

By RICHARD OWEN, F.R.S.,
Hunterian Professor and Curator of Museum of Royal College of Surgeons, Corresponding Member of the Institute of France, &c.

[Reported expressly for the "Medical Times," and revised by the Lecturer.]

LECTURE XII.

Generation of Crustacea.—Characters of the class and of its leading divisions—All true Crustacea diœcious, but the males of some Entomostraca problematical or unknown—Male organs of Cyclops and Branchipus—Widely diffused testes of Limulus and its double tubular penis—Male organs of Isopoda, of the Brachiurous Decapoda or Crabs, and of the Macroura (Lobsters, Shrimps)—Spermatophora; claspers—Complete bipartition and symmetrical arrangement of the male organs—Abnormal dimidiate hermaphroditism—Ovaria and external ovisacs of Branchipods—Dorsal winter-nests of Daphne—Large and diffused ovaria of Limulus—Internal organs and ventral marsupium of Isopoda and Amphipoda—Female parts of Stomapoda and Macroura: Bursa copulatrix of Brachyura—Impregnation of Cyclops by appended Spermatophora.

Mr. President and Gentlemen,—The class of invertebrated animals, the generation of which forms our present subject, may be by some supposed to have been commenced in the preceding lecture, for, in fact, if we were only acquainted with the Lernæans and Cirripedes in their locomotive larval state, without doubt these would have been classified with the Crustacea, and the barnacles more especially with the bivalve Entomostracans.

I know no class of animals which must impress us so strongly with the necessity of careful investigation of the individuals at every stage of their development than the two classes *Epizoa* and *Cirripedia*, in order to determine their affinities and position in the scale of nature. In tracing the progressive change of organs in the animal kingdom, the organs of vegetative life much more rapidly acquire their full development than those of animal life. In reference to the latter, we find a more regular gradation of perfection as the classes ascend in the scale. Take the Articulate sub-kingdom for example, the Entozoa may show a complete alimentary canal, with mouth and vent, and with salivary and biliary cœca: they may have the sexes separate, and the male and female organs marvellously developed, yet be devoid of every trace of a locomotive organ, and have a smooth, soft, continuous, lubricous integument. In the Annelida we found the integument firmer, but alternately harder and softer, so as to be divided into segments with flexible articulations, and in the higher forms of this class, each of the joints was provided with distinct limbs or members, although these presented the lowest form of simple tubes including protractile setæ. In the Epizoa we saw the limbs presenting a true jointed structure, although temporary; whilst in the Cirripedia several pairs of jointed limbs are retained in the adult state, but their rapid actions are subservient to the requisition of food, not to locomotion.

We now arrive at a class of articulated animals in which some or all of the annular segments of the skeleton of the body are constantly provided with articulated limbs or appendages; in which all the species are free and locomotive, and are provided with distinct respiratory organs. These animals are still, however, aquatic; only a part of the class can support themselves and move with their jointed limbs on dry land; the highest act of locomotion is that of climbing reeds or trees, which a few species of the present class are enabled to effect by long prehensile claws. But the breathing organs in all the species are organised for aquatic respiration; in other words, are branchiæ; and it is the combination of branchiæ with jointed limbs and distinct sexes which constitutes the essential character of the class *Crustacea*. The true branchial organs differ comparatively little in the different Crustacea; but in the land-crabs the chamber which contains them is enlarged, and the orifices are diminished, so that a quantity of water is retained for moistening or floating the branchial filaments; and, as fast as the oxygen in the water is exhausted, more is obtained from the air in which they live.

The name of this class refers to the modification of the external tegument by which it acquires due hardness for protecting the rock-dwelling marine species from the concussion of the surrounding elements, from the attacks of enemies, and likewise for forming the levers and points of resistance in the act of supporting the body, and moving along the firm ground. In the crab and lobster tribes the external layer of the integument is hardened by the addition of earthy particles consisting of the carbonate, with a small proportion of the phosphate of lime. This crust is coloured by a pigmental substance, diffused more or less irregularly through it; and it is formed upon and from a vascular organised membrane or corium, which is lined by the smooth serous membrane of the visceral cavities. In the smaller Crustacea the tegument retains a flexible, horny, or pergamenceous texture. In all the species the integument has for its basis a peculiar animal tissue called Chitine, which is not soluble in caustic potass, does not shrivel and consume like horn when burnt, but presents an analogy to the woody fibre of the vegetable kingdom. In the larger species, where this is combined with such a proportion of carbonate and phosphate of lime as to be firm and brittle, it is, as Aristotle has observed, less hard and less brittle than the true shell of the testaceous mollusks, whence that philosopher called them "Ostracoderma," but gave to the Crustacea the name of *Malacostraca*, which name is still retained for that division of the class, which alone was known to the Greek naturalist.

Whatever be the consistence of the external integument or skeleton, it is always disposed in a series of segments, either actually separate and moveable on each other, or confluent in a variable extent and degree, so as more or less to obliterate the traces of their primitive distinctness. Although the body is segmented, the segments are variously proportioned and combined, so as generally to permit the entire body to be divided into three parts, viz., the head, the thorax, and the abdomen; and most of the Crustacea manifest their peculiarly distinctive forms by different combinations and proportions of the same number of primary rings or segments. Each ring, again, consists of certain elementary parts, which, by varying their proportions, contribute to the peculiar form of the region of the body, into the formation of which they enter.

There may be distinguished in the annular segment of a Crustacean, a dorsal arch and a sternal arch, each consisting of a median and two lateral elements; the lateral elements in the upper arch are called "epimeral," and in the lower one "episternal," pieces; the middle element above, or "tergum," consists of two pieces united in the middle line, and that below, or the "sternum," has the same structure. In a great proportion of the class, the body consists of twenty-one of these rings, of which seven are more or less blended together to form the head, seven more obviously enter into the formation of the thorax, and the remaining seven constitute the abdomen or tail.

The Crustacea, with seven thoracic and seven abdominal segments, form the sub-class for which the name *Malacostraca* is retained; but a few large species, and a very great proportion of the smallest members of the class, have the thorax and the abdomen composed respectively of a greater or a less number of constituent segments than seven; these Crustacea form the class *Entomostraca*, which is subdivided into the *Xiphosura*, in which the last segment of the body forms a three-edged sharp pointed weapon, and into the *Entomostraca* proper.

The Xiphosura, typified by the *Limulus* or Molucca crab, have the head and thorax more completely blended together than in the true crabs, which they resemble in the general form of the body; but they are peculiarly distinguished from all other Crustacea by having the office of jaws performed by the first joint of the thoracic legs, which surround the mouth. The large cephalo-thoracic segment is protected above and laterally by an expanded semilunar shield, obscurely divided by two longitudinal impressions into three lobes, supporting the organs of vision on their highest part. The tergal parts of the segments of the second division of the body are also blended into one trilobate clypeiform piece, their original separation being indicated by the branchial fissures, and the number of the segments by that of the lamelliform appendages attached to their inferior surface. The termination of the intestine beneath the last segment of the second division of the body of the Limulus proves that division to answer to the abdomen in the Malacostraca; but, admitting the sessile eyes to indicate a distinct segment, not more than sixteen segments can be determined, by the appendages, to enter into the composition of the entire crust of the Limulus, including the sword-shaped appendage, which is analogous to the last or post-anal segment of the higher Crustacea, and consists of a single modified segment.

In the small Entomostraca, the number of the thoracic and abdominal segments generally exceeds that in the Malacostraca. The *Branchipus stagnalis*, for example, has eleven thoracic segments, and nine abdominal or caudal rings, besides a distinct head protected by a cephalic shield. In the *Isaura*, in which this shield is developed, as in the *Cypris*, *Daphnia*, and other Entomostraca, to the extent, and in the form, of a bivalve shell, enveloping the whole body, the number of thoracic and abdominal segments exceeds twenty four.

The distinction between the Entomostraca and Malacostraca in the number of the segments of the body is of the first importance in determining the affinities of the ancient extinct Crustacea, called Trilobites; to which subject I shall again refer in the comparison of their fossils with certain larval forms of actual Entomostraca.

We make the easiest and most natural transition from the lower forms of Articulata to the Crustaceous class, by passing to it from the larval forms,—which I have argued to be the typical ones,—of the *Epizoa* and *Cirripedia*: in which view we may regard the Crustacea as representing those larvæ on a gigantic scale, and so retaining the typical character with the faculty of locomotion.

All Crustacea, however, differ from the Epizoa in being branchiferous; and from the Cirripedia, in being diœcious.

But, with regard to some of the smaller Entomostraca, only the females have hitherto been discovered; and some naturalists have endeavoured, as in the case of the *Aphides*, to solve the phenomena of parthenogenesis in such Entomostraca by alleged gynandrism. Thus, in the genus *Apus*, the lamelliform respiratory sacs which, after death, get distended with blood, as Siebold has shown, were described by Berthold to be the testes co-existing with ovaria, which are large and conspicuous. Again, in the genus *Cypris*, Straus-Durhheim points out a pair of sacculi at the fore-part of the stomach, but, with his usual philosophic caution, doubtfully alludes to their nature as either testes or salivary glands: they appear to me to be homologous with the cœca in the Daphnia, which most comparative anatomists have agreed in determining to be the liver; there is no other part that could be mistaken for a male organ.

In the genus, *Daphnia*, the males are well known; they are always smaller than the female, but have longer and larger antennæ. Muller deemed these antennæ to be themselves the male organs; they are, however, only accessories, like the claspers in the sharks, being provided with a hooked claw for holding on. Straus points out a modification of the lateral borders of the shell, and suggests that thereby the valves of the female's shell are divaricated, and the sperm ejected into their inter space. The ovaria are simple cœcal tubes, coiled subspirally, one on each side the hinder half of the abdomen. Several groups of ova are successively hatched within the bivalve shell, and the young are excluded during the spring and summer; these young ones propagating in a similar way, without fresh impregnation: the males do not appear until the autumn, and the ova which are then impregnated are

retained in peculiar receptacles throughout the winter months, and are hatched in the following spring.

In Autumn an opake layer is developed on the inner surface of the common incubating cavity; which hardens in two pieces like a small bivalve-shell, with their concave opposed inner surfaces forming a special cavity when the valves are closed; this is called the ephippium, or saddle, being placed on the dorsal surface of the *Daphnia*, but beneath the common shell. Between the valves of the ephippium is formed a similar but smaller apparatus, attached only to the dorsal symphysis or hinge of the carapace, which also affects the form of a small bivalve shell: this is the "*ephippium internum;*" it includes, also, two bivalve capsules, in each of which an egg is lodged, which remains in the passive state through the winter.

If the mother have strength to undergo a moult after the formation of the winter nest, this is cast off with her outer skin, which remains with the ephippial apparatus, protecting the eggs during the winter. They are hatched by the early warmth of spring, and produce only females, which, after moulting three times, exclude a batch of ova. Now, if these be insulated, a successive production of fertile females may be observed to the sixth generation. But the germ cells retained unchanged in the developing *Daphnia* acquire the superadded yelk and chorion of an ovum, from which the young are excluded. The males are a later production, and the winter eggs are always the products of impregnation.

In the genus *Cypris* the ovaria consists of two long cœcums, curved, and applied to the sides of the hinder half of body, but covered by the shell, and opening exteriorly, one by the side of the other, at the fore-part of the extremity of the abdomen, where they communicate with the canal formed by the incurved tail.

The first two-thirds of the ovarium lies free in a capsule, formed by the membrane which lines the valves. The ova are minute at the blind beginning, but progressively augment in size as they approach the outlet, or the fixed vertical and terminal part of the oviduct. These little Entomostraca oviposit on some fixed foreign body, agglutinating their ova in a mass of some hundreds derived from several individuals, by a substance of a greenish filamentary structure like moss. Thus, like the ostrich, many individuals contribute to one nest. In four days and a half the eggs are hatched; the young come out in form like the parent; there is no metamorphosis, only the valves are of a slightly different form, and of a red colour. As the pools dry, they bury themselves in the sand or mud at the bottom; if that remains moist, the old animals survive; if it becomes dry, they perish, but their eggs retain their latent life, and are hatched on the return of rain. This explains the seemingly marvellous phenomenon sometimes observed in a shallow pool, which has been dried up in the summer, and may have long remained so, but which, in a day or two after it has been refilled with water, is found swarming with little *Entomostraca*.

In the *Branchipus stagnalis* we have another example of the rapidity of the appearance of swarms of individuals in recent pools through a similar economy of latent vitality of the ova. The *Branchipus* is characterised by the great number of its segments; the males are distinguished by their antennæ having long antler like terminal joints or processes, which serve to retain the female; and at the termination of the sperm-ducts are two intromittent plates. There are two sperm-sacs and two testes in the form of long and straight cœca, which extend the whole length of the tail; and from the anterior dilated end the sperm-duct proceeds inwards and backwards. Both sperm-ducts soon after their origin dilate into a sperm-sac; and then proto a swelling at the base of the tail, where they open near a spine-bearing peduncle. The *ova*, when they are impregnated, are received into an external capsule. When the pools are dry, the ova have the power of retaining life for two or three years.

To the sub-class *Entomostraca* belongs the great mollucca or king-crab. (*Limulus.*) The generative organs attain an enormous extent in this species; they are packed closely, interblending with the ramified cœca of the liver, in both male and female, throughout the body. In the female the ovarian tubes present the dendritic or ramified disposition. We distinguish the sexes by the external character of the first pair of thoracic limbs, which are short, swollen, and hooked in the males, while in the females they are long, straight, and pointed. On the first of the abdominal respiratory limbs there is a prominent tubular appendage, on which the sperm-duct terminates; in the female there is a simple perforation at the corresponding part.

No instance of parthenogenesis has been determined in the higher sub-class of Crustacea, called *Malacostraca;* but like other Articulata subject to periodical ecdysis, the Crustacea have the power of reproducing lost extremities. If a leg be fractured or severed across one of its segments, it is cast off by a violent muscular effort at the second articulation: if the Crustacean have not the power of thus ridding itself of the wounded member, it usually dies from the hæmorrhage; but this is immediately arrested by the contraction of the lacerated part of the joint where the limb is cast off with least difficulty and pain, and where a groupe of germ-cells has been retained in prospective preparation for the needful reproduction. A small cylindrical appendage first sprouts from the cicatrix, which soon after presents distinct articulations, and resembles in miniature the limb which it is destined to replace: its growth is slow until the period of the moult, when, if the animal be in vigorous health, the new member rapidly acquires its normal size.

There is no propagation by spontaneous fission or gemmation in the class *Crustacea:* every species is developed from ova formed by organs peculiar to one series of individuals, and impregnated by the fertilising product of organs as peculiar to another series. But, although the male and female organs are never naturally combined in the same individual, accidental or monstrous hermaphrodites occasionally occur, in which the male organ is developed on one side, and the female organ on the other side of the same animal. This dimidiate hermaphroditism, as I have termed it, has been most commonly observed in the lobster, and is indicated by external characters. The generative orifices open on the last thoracic leg on the male side, in which the abdominal plates are smaller and more simple; whilst on the opposite side they are broader and more ciliated, and the generative aperture is situated on the middle or third ambulatory leg.

This singular kind of malformation seems to depend upon the very slight connexion, or want of connexion, between the right and left generative organs of the same individual, whether male or female. The external apertures are always distinct on each side; and when a combination of the right and left generative organs does occur, it is by a partial union of the two testes, or of the two ovaria.

In the male *Cymothoa* both the essential and efferent portions of the male apparatus are distinct on each side: the testis is here much simplified, and consists of three elongated pyriform vesicles forming a common tube by the union of the short vasa deferentia, which arise respectively from the great end of each vesicle. In this and some other of the *Isopoda*, the disproportion between the male and female is still retained; and is almost as extreme in the parasitic *Bopyrus* as in the Lernæans.

In the *Astacus fluviatilis* the testes are blended together at the middle line along the posterior half of their extent, anterior to which they are separated and symmetrical: they consist of packets of minute contorted capillary secerning tubes. The vasa deferentia quit the gland at the junction of its three apparent lobes: they form many convolutions at the sides of the hinder part of the thoracic segment, where they may be distinguished by their opake white colour. They dilate into sperm receptacles in the last portion of their course, and terminate at the small prominent orifices at the basal joints of the last pair of thoracic legs.

In the *Maia* the testis consists of an elongated and convoluted mass of extremely minute vermicular tubuli, which mass is united by a slender transverse commissural process with the testis of the opposite side. The vas deferens is formed by the gradual enlargement of the tubuli, and is disposed in a number of close convolutions, and somewhat suddenly dilates into a spiral seminal receptacle, which terminates, as in the *Astacus*, on the basilar piece of the last pair of legs. In many crabs, however, as in the *Grapsus* and *Ocipoda*, the external opening of the male organ is found on the sternal part of the last thoracic ring. The terminal part of the duct can be everted by a kind of erection to form a temporary organ of intromission; and the Crustacea are singularly analogous to serpents in the double number as well as the structure of this part. Certain appendages of the first and second abdominal rings in the male crabs are probably connected as exciting organs with the sexual function.

The female organs present, like the male, a progressive complication of structure as the species ascend in the class. Most of the small Entomostraca carry the impregnated ova in appended ovisacs, like those of the Lerneæ. These sacs are not developed in the Limulus, which also differs from the smaller Entomostraca, inasmuch as the ovarian mass interblends its lobes and processes with those of the liver; the oviducts form more frequent communications with each other than in the higher Crustacea, but ultimately terminate, like the vasa deferentia, by two distinct but continuous orifices on the back part of the first abdominal lamelliform appendage.

The ovaria in the lobster are of great length on each side; the oviduct comes off from the outer part of nearly the middle of the gland, and descends to terminate at the basal joint of the third pair of ambulatory feet.

In the Brachyura the female apparatus reaches its highest state of complication, and consists of an ovary, oviduct, and a copulatory pouch, or spermatheca, on each side. The ovaria are elongated cylindrical sacs in the *Maia*, and are divided into an anterior and a posterior part, the short oviduct being continued from the union of the two: the anterior parts of the ovaria are united together by a short transverse canal; the posterior divisions are very intimately united through half their extent: the spermatheca is developed a little above the termination of each oviduct; and the sphermatophora and spermatozoa in this receptacle afford favourable subjects for microscopic observation.

The species of a genus of Macroura (*Mysis*) are called "Opossum shrimps" from carrying their ova during the process of development in abdominal recesses, analogous to the marsupial pouch; but this superadded complexity in the reproductive economy is common, under various modifications, to all the Crustacea.

The metamorphoses and development of the higher Crustacea will form the subject of the next lecture; but in concluding the present I shall revert to the Entomostraca in order to notice the singular generative economy of the Cyclops, discovered by Professor Siebold. In the male, the right antenna is peculiarly thickened and jointed a little beyond its middle, so as to permit it to be bent upon itself. With this organ the male seizes the female, and then grasps the base of her tail by the great hook of his hindmost pair of feet. After a slight resistance, she is quiet, and both gradually sink to the bottom. A cylindrical tube, fitted with sperm, escapes from the orifice of the male organ, and he seizes the tube as soon as it has escaped, and glues it to the abdomen of the female above the vulva. No female has this tube prior to the coitus, and none is without it afterwards. A male fit for coitus always has this tube or spermatheca in the lower dilated half of his seminal canal, and after the coitus it is no longer there.

On one occasion, Professor Siebold, disturbing the attached pair found the "sperm-tube" attached to the rounded end of the last pair of feet of the male, indicating the instrument of fixation. The females so provided are not, therefore, disdained by other males,—three, four, or even six spermatophora may be found attached to the same female. The sperm-tube consists of three different kinds of substance, spermatic matter, expulsatory cells, and

agglutinating matter. The action of the cells, in expanding, is to push out the spermatozoa, which as the sac is suspended to the ventral surface of the first caudal segment, thus escape close to the vulva

The Cyclops has a single testis, which is a pyriform sac concealed in the dorsal region, beneath or behind the heart. A long and wide sperm-duct descends to the inferior half of the body; then rises abruptly, and again descends by a sudden curve, to arrive at the sexual opening, which is simple, and at the middle of the base of tail. In the pyriform testis are sperm-cells and also spermatozoa. In the descending part of the sperm-duct is the spermatophore.

How they become occupied with their proper threefold contents has not been observed, but it does take place gradually as the spermatophore descends towards the spermatic outlet. There is no proper coitus, *i.e.*, the male does not intromit directly; but he appends or attaches the spermatophore to the female. Each spermatophore contains, besides spermatozoa, two other substances; one expulsatory, which swells in water, and expels the spermatozoa; the other coagulates in the water, and serves for the attachment of the spermatophore. The contemplation of the complex machinery requisite for this curious mode of impregnation, whilst it exemplifies the necessity of direct contact of the spermatozoa with the ova, must fill the mind with admiration at the perfection which is manifested in subserviency to the propagation of an animal, so minute and seemingly so insignificant.

LECTURES
ON
OPERATIVE OPHTHALMIC SURGERY.
DELIVERED AT THE CENTRAL LONDON OPHTHALMIC HOSPITAL.

By H. HAYNES WALTON, Esq., F.R.C.S.,
Surgeon to the Hospital, and to the St. Pancras Royal General Dispensary.

LECTURE V.

Question of binding up the eye after operating.—Patient to be sent to bed; rules enjoined; kind of aliment required.—Manner of cleansing the lids.—Examination of the eye.—Impropriety of premature examination.—Nature of success.—Causes of failure.

GENTLEMEN,—In the present lecture I propose considering the subsequent treatment, and the general results of the operation of extraction. It is thought by some absolutely necessary to bind up the eye, and various are the methods of effecting it. That usually followed, is to place a pledget of rag, either wetted, or dry, or smeared with some unguent on the lids, and confine it by a bandage. Strips of plaister are occasionally preferred; they are passed from the forehead, across the lids, to the cheek. I believe all such treatment to be highly objectionable. Any degree of pressure, however slight, on a wounded eye, can never be beneficial, and is always likely to be prejudicial. The heat and discomfort inseparable from coverings must often give a disposition to, if not actually produce, inflammatory action, which it should be our anxious care to avoid.

No appliance can improve the adaptation of the edges of the cornea beyond what is effected by the contact of the upper lid. For the fullest advantage to be derived from that natural covering the eye should be closed; and, doubtless, to accomplish that, it has been thought requisite to employ the contrivances I have mentioned. Really, such means are unnecessary,—for the patient has no difficulty in keeping the lids shut. If he is determined to open them, that bandage, or covering, must indeed be tight, that can restrain his folly.

Sometimes, for form sake, or to produce a moral effect when the patient has been nervous, and fancied that he would open the eyes unless a bandage were worn, I have attached a bit of cloth to the night-cap, sufficiently long to cover them, and over it passed very lightly a single turn of a common roller. But that has not been without its disadvantage, for the discharge of aqueous humour, and may be the lachrymal secretion, sometimes wets the cloth, whereby it adheres to the face and produces sufficient discomfort to disturb or prevent sleep.

I prefer to send my patient to bed immediately that the operation is over; and, to prevent inconvenience, perhaps accident to the eye, I require all the principal articles of clothes to be taken off before the operation, and a morning gown put on.

The globe of the eye should be kept quiet, and, although in a properly darkened room, (for light should be excluded from the apartment,) there is little tendency to move it about; the patient should be admonished respecting it. He should be told, also, to endeavour to suppress any inclination to sneeze or to cough. It is most necessary to have a nurse that can be depended on for attention, and the strict observance of orders. Patients, in all classes of life, will disobey medical orders, especially in matters of eating and drinking. The watchful eye of an attendant is often needed prior to operation,—for under the idea of keeping up courage and strength, strong drink is frequently taken before the surgeon's arrival.

Unnecessary talking should be avoided, and no subjects likely to create anxiety, or produce mental emotion, should be introduced; the greatest quiet should be observed.

To ward off injuries or blows, or the unconscious application of the patient's fingers, I like a large shade of some stiff material to be worn. To be sufficiently protective, it should completely encircle the temples, and extend from the forehead nearly to the tip of the nose.

For the first two days, the food should be of the simplest kind and fluid, or not sufficiently solid to require much mastication. Old persons are sure to grumble on a slop diet, and find some objection to almost everything that is proposed. Bread and butter, with tea, most generally pleases them.

As a rule, animal food and stimuli should be prohibited till the period at which inflammation is likely to occur has passed. Under special conditions, however, they may be required from an early period. I have known much prostration quickly follow the operation.

If, on the first day, at the usual bed-time, there is restlessness, with much disinclination to sleep, I prescribe some narcotic, unless I am told it is likely to disagree. I generally give hyoscyamus.

From day to day, the corners of the eye, and the lower lid, should be carefully cleansed of any secretion or incrustation that may be present. I fancy it is better not to meddle with the edges of the lids if they are clean and comfortable; the contact of any body, however soft, is apt to throw some of the orbital muscles into action, and produce pressure on the globe. After the second day, they generally become adherent, except at a spot or two, by which the aqueous humour escapes. I do not think that any disadvantage arises from the adhesion. If it is objected to, it may be prevented by applying some simple ointment.

When the edges of the lids do require to be bathed, the circumstances demanding it, viz., the presence of pus, or muco-purulent secretion, arises from inflammation; and there is great sensibility to touch. The least painful way of cleaning them is to fold a bit of soft rag, so as to form a point or angle, which should be dipped into warm water, gently drawn along the edge of each lid till the secretion is removed, and then a dry cloth used. Only just enough light should be admitted to see what you are about, or, if a candle be used, it should be shaded.

The lachrymal gland, sympathising with the injury the eye has received, pours out its fluid; and this, together with the aqueous humour, which continues to be secreted although the cornea is divided, passes from between the lids, either in gushes or by trickling. The lachrymal tubes seem incapable of carrying off the inordinate quantity.

When five clear days have passed without unfavourable symptoms, success may be looked for; and on the sixth, after the edges of the lids have been thoroughly moistened with warm water, should they be sticking together, the patient may be allowed, unaided by the surgeon's fingers, to open them sufficiently to enable him to discern any surrounding objects. Too much light must not be allowed for the experiment. It must always afford great satisfaction and delight when, in compliance with your request, any object is named by him. Then the bed must be resigned for the couch or arm-chair.

I am aware that so long a confinement is thought by many to be useless. There are cases in which it is unnecessary, but they must be looked on as exceptional; two of such have been in the Hospital this summer. John Bourne, aged 65, operated on June the 22nd. On the 25th, he told me that he had been trying his eye, and could see; and, on the 27th, he would, contrary to orders, leave the house. In autumn of last year I operated on the first eye, and it was not till the eighth day that he could open it. The second case was a male, aged 82, who was with difficulty kept after the third day. I have no doubt that the cornea had healed in twenty-four hours. Nowhere else is a patient so secure from injury as in bed; and, when it is remembered what is at stake, a few hours passed in the recumbent posture should not be considered burthensome. After the second day, I have no objection for the patient to rise to allow the bed to be made.

Light should be admitted into the apartment as soon as the eye will bear it; of course, gradually at first. As soon as the patient begins to move about, the eye commences to water more or less, even if it have not been running before, which, I think, is a pretty sure indication that perfect rest of the organ for the few first days is very necessary.

Exercise should be taken when circumstances will admit of it.

Restoration to sight is often effected without any inconvenience beyond the necessary confinement. Much pain rarely attends a successful case. When destructive inflammation ensues, it produces the most intense suffering.

I am desirous to warn you against the pernicious practice of opening the eye at very early periods, to see, as it is expressed, "how the case is going on." The desire is to expose fully the upper part of the cornea; but the patient not being able to open the eye sufficiently for the purpose, the upper lid, which is always very tender and sore, is raised, and he is told to look downwards, the pain which arises is certain to produce involuntary resistance, and all the disadvantage attending the spasmodic action of the orbital muscles is encountered. I am sure that many failures are produced by such interference. Several times have I observed the first bad symptom to commence from the period of the examination. If nothing worse follows, there is generally more or less pain, which may last for some hours. Should the cornea not have healed when the examination is made, the probability is that prolapsus of the iris is produced, by a gush of aqueous humour; and if it is already prolapsed, there will be an increase in the amount protruded. What is most to be dreaded is the accession of acute inflammation.

An early examination cannot be of use, if the case is progressing favourably; if otherwise, it will aggravate mischief; and in no instance can it disclose any symptoms for guidance, further than are indicated by the state of the lids, particularly the upper one, and the sensations of the patient.

During the confinement to bed, the action of the bowels must not be neglected; if the third day arrive, and no evacuation is passed, some slight purgative, as pil. rhei. co., or a small dose of oil, or an enema, must be given. As there is harmony of action between the eyes, that not operated on should be closed as long as its fellow, in order that it may be kept quiet.

When success is said to attend extraction, do not conclude that there has been perfect restoration of sight. Under the most favourable circumstances, the eye is never what it has been. There must be artificial compensation for the loss of the lens, and no ingenuity will admit of that rapid adaptation of the eye from near to distant objects, which is so essential to complete vision, and so beautifully provided for in the natural state. Besides, erroneous impressions are frequently conveyed by the too unqualified use of the term successful.

The popular idea of cataract is a scale, or film,

growing over the eye, and, reasonably enough, the blind man thinks that, on its removal, his eye will be as good as ever. The after necessity for glasses is unsuspected, unless they have already been worn.

As the surgeon will assuredly be questioned on the result of an operation, I consider it desirable—nay, his duty—always to let it be clearly under stood, that there are degrees of a favourable result, ranging from excellent vision to sufficient sight for the ordinary purposes of life, but scarcely for minute objects. That two sets of glasses are always required, the one for reading, writing, or examining near bodies, the other for distant ones. Further than this, he should be very careful, even under the most favourable circumstances, never to over-rate the chances of success, and induce the patient to think the operation infallible; and, above all, whenever there is the slightest indication to render the result questionable, all the particulars for and against operating should be made clear and intelligible to the patient, or to some confidential friend or near relative. These observations are meant to apply to all operations undertaken for cataract.

I had intended to give some cases of remarkably powerful sight after extraction, but desist, as it would detain you too long. Suffice it to say, that the eye may be capable of seeing any body however minute, that could be discerned before cataract affected it.

As an exemplification of far-sightedness, I may mention what a man, who was in the coast-guard service, from whom two cataracts had been extracted, told me:—"That, with his proper glasses, he could see a ship, or any object at sea, as quickly and as far as his comrades."

I shall briefly recount the usual causes of failure, which I arrange under the following heads:—

Acute Inflammation.—This appears early, generally within the first twenty-four hours. The conjunctiva is first attacked, and afterwards the other textures of the eye.

Almost suddenly, acute pain is felt in the eye-ball, then in and around the orbit. Purulent discharge soon follows; as may be expected, the vascular and nervous systems are deranged. The worst result is infiltration of the cornea with pus, and suppuration within the globe. The suffering induced is, in spite of all treatment, most intense. A less violent termination is thickening of the capsule of the lens, with adhesions of its divided portions, or adhesion of the capsule to the iris, or closure of the pupil.

The usual remedies supposed to subdue acute inflammation must be resorted to, with the exception of antimony, which may induce vomiting; for the same reason venesection should not be allowed to produce syncope. It is said that mercury will interfere with the healing of the cornea, and is contra-indicated. I do not know that such a prejudicial effect has been proved. But, beyond its use as a purgative, it could scarcely be available; for, if the inflammation be not subdued before the usual time required for the specific effect of that remedy, there could be little chance for the case.

Blood-letting and purgatives are, therefore, the means to be used, and the general principles of treatment must direct their employment.

I never saw a case in which there had been an accession of violent inflammation, notwithstanding the most active treatment, that did not terminate with more or less damage to the eye. If, on the first onset of inflammation, decisive and energetic treatment do not subdue it, hope of success must be resigned. After the best recoveries patients are debilitated, and the importance of not unnecessarily increasing that state is obvious.

I must guard you against taking the occurrence of any pain, however slight, as a signal for depletion. Numbers of the supposed instances of acute inflammation, said to have been cut short by active means, have been no such thing, and on many of the occasions the patients would have done better if left alone. Frequent attempts that have been made with the lancet and purgatives, to subdue slight pain, have sealed the fate of the eye.

Sub-acute Inflammation.—Mr. Tyrrell was ever desirous to impress his pupils with the important fact, that two distinctly recognisable forms of inflammation attack the eye after operation, both equally painful and destructive, and each requiring distinct treatment. The first has been disposed of, but, for the advantage of contrast, I shall recapitulate it previous to describing the second or sub acute form.

The acute inflammation appears at an earlier period; the lids are bright red, and the conjunctiva highly injected with red vessels, and the secretion purulent. The sub-acute comes on some days after the operation; the swollen lids scarcely have a blush of inflammation, being rather of a darkish blue, and infiltrated with serum, particularly the upper one. The secretion is thin and not decidedly purulent, and the conjunctiva scarcely vascular, although chemosed. The character of the palpebral swelling, and the nature of the secretion from the lids will offer sufficient guidance, and render unnecessary the opening of the eye to look at the conjunctiva.

The state of the system is the reverse of that in the acute attack; the circulation is feeble or languid, and the extremities devoid of their natural warmth. Depression of spirits and a sense of sinking are accompaniments. The treatment under such circumstances is to support the system. The hard, unyielding pulse of old persons, arising from the change that the blood-vessels have undergone, is likely to mislead. When the condition of the lids, and the feelings of the aged patient, indicate that general power is required, the hardness of the pulse must not be taken into account. On the other hand, we should be careful not to let it induce us to deplete *too much*, when there is some necessity for that treatment.

In no other set of cases narrated in Mr. Tyrrell's work is the effect of treatment more clearly and certainly shown, than those of sub-acute inflammation occurring after extraction. His practice was to give strong broth, or other nutritious matter in solution, with beer, wine, or spirits. Medicinally he prescribed carbonate of ammonia, and when there was restlessness besides, he combined opium with it.

I have been describing the well-marked extremes of the acute and sub-acute forms; instances, however, arise where the local and the general symptoms do not enable the practitioner to decide on the exact character of the inflammation, and the line of treatment is not clear. Mr. Tyrrell, to test the genuineness of such doubtful cases, recommends the carbonate of ammonia to be given in doses of 8 or 10 grains, with or without opium, and he says, if the inflammation be sub-acute, relief of the symptoms soon follows its administration, while, if it be acute, there will be an aggravation of them.

The first extraction I ever performed was followed by sub-acute inflammation. There was considerable pain; the cornea became hazy; the cut did not heal, and the iris was prolapsed. Large doses of liquor cinchonæ, with animal food and porter were given. The effect was very marked, and the eye was saved.

The circumstance made a strong impression on me. I had just commenced to attend Mr. Tyrrell's practice, and did not know his views; as yet his book had not appeared. Being then connected with a distinguished surgeon who was in the habit of adopting the antiphlogistic treatment most vigorously in all instances where pain followed an ophthalmic operation, I was about to imitate his practice, when the advice of a friend, to whom I applied, altered my intentions. When any pain is felt after the operation, my usual practice is to give a dose of hyoscyamus, and wait to see what ensues before adopting other means.

Prolapsus of the Iris.—This is the most frequent cause both of failure and of imperfect success, whether the prolapsus occur at the period of the operation, or subsequently.

With protrusion of the iris, the pupil is necessarily displaced, altered in form and restricted in motion, and the nearer it is dragged to the margin of the cornea, and the smaller the opening that remains, the less perfect will be vision.

The prolapse may be so great as entirely to destroy the pupil.

In some instances, the pupil, although displaced and irregular, is enlarged much beyond its natural size. The iris sometimes contracts an adhesion to the line of incision of the cornea, but does not protrude; the only disadvantage of which is, that the pupil is a little irregular, and cannot contract and dilate freely. Such an adhesion almost always follows a wound of the iris.

Of primary prolapsus I spoke when describing the operation.

Some of the causes of secondary protrusion are, rough handling of the eye, and opening it, or allowing the patient to open it, and move the globe about before the corneal section is healed; the occurrence of acute or sub-acute inflammation, straining efforts, pressure of any sort on the eye or sudden action of the orbital muscles. It frequently happens, when there does not seem to have been any reason for it. Tedious recovery is a pretty sure consequence; the delay of the healing process depending more on the extent to which the edges of the cornea are separated, and the position in which the iris lies, than on the amount protruded.

The projection of the flap of the cornea, and the protrusion of the iris is often considerable, yet, in the most aggravated cases, there may be such effectual reparation, that scarcely a trace of former mischief can be observed at the edge of the cornea. The eye should be kept quiet till the adhesion is firm. I object to any local applications; they are not needed, and in the majority of instances irritate an already inflamed and highly sensitive eye.

After watching, very carefully, many cases of prolapsus, both after extraction, and the result of accident, when the cornea has been divided or ruptured, and noticing the treatment adopted, I feel as certain as one can on such a point, that those in which there had been no additional irritation produced by the use of arg. nit., or anything else, make the best recoveries. Nor do I snip off any protruding part, for whatever is superfluous, and not needed in the formation of a proper cicatrix, nature is sure to remove quickly. The only occasion on which treatment may be serviceable is when the iris, bulging out considerably by the pressure of the aqueous humour behind it, forms what is called "staphyloma iridis," and inflammation arises from the mechanical irritation on the lid by the tumour of the prolapse. In the former, the staphyloma may be pricked with a cataract needle, the aqueous humour evacuated, and a better chance afforded for union by the approximation of the edges of the cornea. In the latter, local abstraction of blood, or purgatives, may, perhaps, be beneficial.

There is frequently irregularity of the pupil after extraction when neither prolapse nor adhesion is present. It is owing to the injury the iris has sustained during the stretching of the pupil for the escape of the cataract. The irregularity corresponds to the spot over which the cataract has passed, just, in fact, where the greatest stretching has occurred, and is therefore always in the direction of the corneal section.

Iritis and Closure of Pupil.—Inflammation of the iris may come on within a few hours after the operation without any apparent cause, or as the consequence of injury by the instruments employed. Except the iris were looked at, I do not know of any symptoms by which it is to be recognised from the acute inflammation that I have described. The pain, swelling, redness, and intolerance to light, are in both alike. A knowledge of the iris having been wounded would likely lead to a just suspicion of the nature of the affection. If mercury, the valuable agent in iritis, is contra-indicated on account of interfering with the healing of the cornea, we must employ the same means that were mentioned when speaking of acute inflammation after extraction, and the eye need not be subjected to an examination.

But iritis commonly appears four or five days, or later, after the operation, and cannot be traced to injury. The last case I had, was in the autumn of 1848. On the sixth day the eye was opened, and success pronounced; on the seventh, iritis appeared, and the pupil was closed. Giving credence to the

tales I had heard and read of the likelihood of the adhesion of the cornea to give way when mercury is exhibited, I did not employ it. In future, in parallel cases, I shall certainly try it, and judge for myself. Belladonna should be used from the first indication of the attack. (a)

The Cornea not uniting by the First Intention.—The period at which union is effected varies, it may be, from the second, to the fourth, or fifth day. When it is not effected within the latter period, the eye is always in danger from inflammation, generally of a low type, that is set up, and the iris is prone to be involved in one of two ways,—by prolapsus, or by becoming inflamed.

On the 30th November, 1843, I extracted two cataracts from an old female inmate of the Stafford Almshouse, in Gray's-inn-lane. She seemed to make favourable progress; but, when the eyes were opened, the corneæ, contrary to my expectation were not united. On the 31st December, the right cornea had not quite healed. The aqueous humour spirted out in a very fine stream while I was examining the eye, there being a sort of fistula. In the left eye there was even less adhesion. A very slow inflammation invaded each iris, and the pupils were closed. The corneæ did not become opaque, as is usually the case. Ultimately the cuts were closed. The globes did not shrink. A great deal has been said about the cornea not uniting from want of sufficient general power. Although there can be no doubt that a great many of the cases evince that deficiency, and require to be supported, and the circulation invigorated, it has been too much the fashion to attribute failures of union to such a cause.

I had almost forgotten to mention, that aquocapsulitis may appear several days after extraction producing considerable lachrymation, and more or less intolerance of light, but not much pain. There is usually no vision while it lasts. It ultimately gets well, and sight is restored.

It is not uncommon for acute conjunctivitis to supervene some days after the patient has been moving about.

It must be remembered, that an operation on an unhealthy eye will, in almost all instances, fail. hence the necessity for great discrimination and judgment in the selection of your cases.

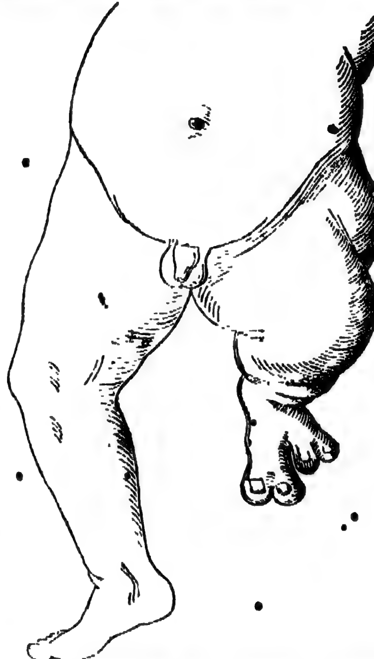
When, after operation, the globe gradually shrinks without the occurrence of active inflammation, and sufficient time for chronic inflammation to produce disorganisation, you may conclude there was a previously diseased state. I gave one example of this in the third lecture. Without any of the circumstances that I have mentioned having occurred, and without any apparent cause, at the usual period of examining the eye it may be found amaurotic. Only one example has come under my notice.

Having scarcely alluded to the satisfactory results that attend extraction, and dwelt at length only on the failures, and given a long catalogue of dangers and disasters, I fear that I have made you regard it as a formidable affair. In competent hands, the difficulties of the operation, and, consequently, the principal dangers attendant on it disappear.

I have said that prolapsus of the iris, whereby the condition of the pupil is affected, is the common cause of failure. I used the word failure, because virtually it is such when the extraction does not restore sight; but the power of seeing may yet be gained by a second operation, in the formation of an artificial pupil, in those instances, and where iritis has closed the natural pupil.

You must see a large amount of practice before you can be personally acquainted with all the untoward results I have described. Let me assure you, that with well-chosen cases, carefully conducted operations, and judicious after-treatment, the results will fully satisfy you.

(a) Since the above was delivered, I have been informed by my friend Mr. Browne, Surgeon to Belfast Ophthalmic Institution, that he never hesitates to give mercury in inflammatory attacks after extraction, and that he does not believe that its exhibition can prevent the healing of the cornea.—H. H. W.

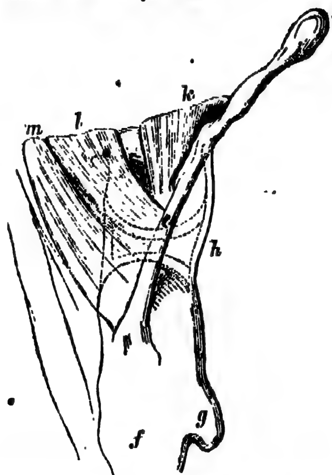


ORIGINAL CONTRIBUTIONS.

THE ANATOMY OF A MISDEVELOPED LOWER EXTREMITY.

By WILLIAM BRINTON, M.D. Londin., Demonstrator of Anatomy in King's College, London.

The following case occurred in the practice of my friend, Mr. J. Gordon Bailey, of Pentonville. The mother attributed the malformation to having been frightened by a cripple during pregnancy. The child lived several months, and died of pneumonia.



The size and general appearances of the limb are sufficiently represented by my sketch. (a)

The limb was exceedingly moveable in the middle of the short thigh, being capable of very extensive flexion and extension, abduction, adduction, and considerable rotation. At the knee-like projection, no motion could be produced. Elsewhere, or at the ankle and the toes, the ordinary articulations could be detected, and the usual movements produced.

As the removal of the limb was forbidden and impossible, I made a rapid dissection of its interior, of which the following is a brief description.

There was no cotyloid cavity. But a large and longly convex mass of cartilage *a*,

with a smooth surface, projected in its place from the innominate bone. Below, the femur opposed it a very similar, but more pronounced convexity *c*. An interarticular fibro-cartilage *b*, like that of the jaw, separated the two surfaces, and a capsular ligament of considerable strength *h* completed the joint.

A strong cord-like ligament, taking very much the course of the ilio-femoral, strengthened the anterior surface of this joint. The muscles of the thigh were all present, though very short. The pectineus *l*, the adductor longus *m*, and the iliacus *k*, were inserted into this cord-like ligament. Beneath it the adductor brevis and adductor magnus, joined the articular capsule; while the obturator externus and small rotators and abductors were inserted into the posterior surface of the capsular ligament, and chiefly into the rim of the meniscus of cartilage.

There was no knee joint; but the notch between *c* and *d* in the vertical section indicates the site of junction of the femur and tibia. The shaded part *n*, in the same figure, represents the inner surface of the rudimentary condyle, the united bones having been divided in their middle and antero-posteriorly, as well as vertically. A tubercle *g*, on the outside of the limb indicates the only rudiment of a fibula present.

The ankle joint, except in the absence of the fibula and the muscles attached to it, appeared normal, as did the tarsus.

The cloven foot consisted of two elements; each of these has three segments. The terminal one is double in both. The middle one is broad, short, and single, in both. The outer posterior segment is single, and is capable of being identified as the fifth metatarsal bone, with which, perhaps, the fourth is conjoined. The inner posterior segment is double; and, from the striking uniformity thus manifest throughout the three segments of this double toe, it seems most likely to be the second and third,—the more so, that the inner line of the tarsus runs straight backwards, without any depression corresponding to that caused by the posterior and inner extremity of the first metatarsal bone, or great toe.

(a) The engraving somewhat exaggerates the size of the malformed limb.

ON SCARLATINA.

By J. W. TRIPE, M.D., M.R.C.S., and L.A.C., London.

(Continued from page 179.)

B. f. Although no difficulty whatever exists in ascertaining the number of deaths in the two sexes at various periods of their existence, yet some considerable difficulty, and a vast amount of calculation, together with very numerous Tables, would be required to properly appreciate the statistics; as the proportionate number of males and of females dying, varies very greatly at the different ages. Thus, 23·349 per cent. of males of the whole number, and only 17·902 of the females, die in the Metropolis before they reach the age of one year; 15·979 per cent. of males, and 15·029 per cent. of females, die between the ages of one and of three years, &c. Now, any Table showing the mortality in the two sexes at the different ages, ought to take into consideration the tendency of disease generally, to prove more fatal to males at one age than to females, and *vice versa*; and to calculate the proportions. These could scarcely be inserted in a weekly Journal, more especially as allowance also would have to be made for the preponderance in the births of males over that of females.

Out of a gross aggregate of 43,540 deaths from scarlatina in various years in England and Wales; 21,887 occurred in males, and 21,653 in females; the actual preponderance, therefore, happened in

the male sex. But as 1,237,986 deaths of males, to 1,200,189 deaths of females happened in England and Wales in the seven years 1838—1844, the proportion of males was not so great as that which occurs from all causes. I make use of the term "all causes" in preference to all kinds of disease, as these numbers include deaths from accidents, suicides, &c.

In the five years 1842, 1843, 1844, 1845, and 1846, the proportions in the metropolis were rather different, as out of 8133 deaths from this disease, 4192 happened in males, and only 3941 in females. Of the 4192 deaths of males, 378 happened during the first year of existence, 1423 between the ages of one and three years, and 1149 between three and five years; making a total of 2850, or about 68 per cent. of the total number. Of the 3941 deaths of females, only 314 occurred during the first year, 1337 between one and three years, and 1027 between three and five years, amounting to 2628 deaths, or about 66 per cent. As, however, the age of the persons dying becomes greater, the mortality in females also becomes greater, until between the ages of ten and fifteen, when the number of deaths in the female sex exceeded those in the male, and continued to do so up to between fifty and sixty, differing in this respect very materially from the returns of deaths from all causes. It will, perhaps, be better to put these statements into a tabular form.

DEATHS from SCARLATINA within the METROPOLIS, Years 1842—46.

	$\frac{0}{1}$	$\frac{1}{3}$	$\frac{3}{5}$	Total under 5 years	$\frac{5}{10}$	$\frac{10}{15}$	$\frac{15}{20}$	$\frac{20}{30}$	$\frac{30}{40}$	$\frac{40}{50}$	$\frac{50}{60}$	$\frac{60}{70}$	Above 70 years.	Total between 5 and 70 years.
Males...	378	1423	1149	2850	948	118	34	46	38	16	15	4	3	1249
Females	314	1337	1027	2628	908	168	41	58	15	17	10	8	3	

We thus see that the comparative fatality of scarlatina in the two sexes varies according to the age; being greatest in the male sex during the first decennial period of existence, and greatest in the female during the second, third, fourth, and fifth decennial periods, and must, therefore, suppose either that a less predisposition, or a greater power of resistance to the virus of scarlatina, exists in the female child during the first ten years of its life, when compared with the male, and the contrary.

The pathology of the disease forms the concluding part of this memoir. By the term pathology I do not only mean those morbid changes induced by the disease which are evident on a *post-mortem* inspection, but the various pathognomonic deviations from healthy action that occur in the tissues or fluids during its course. We are not, unfortunately, sufficiently acquainted with the healthy action and chemical composition of the solids and liquids of the body, to determine precisely when they are normal, and when abnormal; but yet, so many steps have of late been taken in the right direction to elucidate these most important branches of knowledge, that we must not despair of being tolerably acquainted with them hereafter.

The deviations from a healthy state of the fluids and solids of the body during an attack of scarlet fever may be divided—firstly, into those which are perceptible to the unaided senses, as the pyrexia, the œdema of the skin, the redness, swelling, and ulceration or sloughing of the fauces, tonsils, or adjacent parts; the morbid appearances of the alimentary canal, kidneys, &c.; secondly, into those which may be detected by the chemist, as the increased amount of fibrine in the blood; thirdly, into those which may be deduced from, or discovered by a microscopic examination of the diseased parts, or of the disordered secretions; and, lastly, into those which cannot be proved either by our senses when unassisted, nor when they—our senses—are assisted by chemical and microscopic aid. The three first of these classes into which deviations from healthy structure are divided, have been already as fully considered as our space will admit of, but the last has not as yet received any consideration.

It is very evident, that some permanent alteration must be effected in the body by the action of the scarlatina virus on it, inasmuch as a membrane that has once been attacked, is ordinarily rendered insusceptible to the disease in future. This peculiarity is shared by the other exanthemata. On what does this peculiarity depend? Does it arise from a modification of the blood, or of the tissues, or of both? These questions can be answered, and many other points in the history, &c., of the disease, can be elucidated—only by a consideration of the laws of poisons generally, and especially of the morbid poisons. In addition to these, it would be necessary to ascertain as clearly as possible, the functional and organic changes induced in the body by the poison; but as this would involve the consideration of nutrition in its widest acceptance, including healthy, and that variety of abnormal nutrition, which is known as inflammation, and also a consideration of the forces by which the blood is circulated in the capillaries, we must almost entirely pass over their consideration. Dr. Robert Williams, in his elaborate work on morbid poisons was the first clearly to point out the analogy between the action of the ordinary and of the morbid poisons. The laws which he pointed out are the three following:—"Firstly, that all poisons have certain definite and specific actions; secondly, that they lie latent in the system a certain definite but varying period of time before these actions are set up; and lastly, that the phenomena resulting from the poison when roused into action, vary according to the dose or predisposition of the patient. These laws are common to all poisons or classes of poisons." (P. 3.) To these laws we may add a fourth and fifth, viz., that the specific action of poisons depends on the affinity existing between the liquids and solids of certain parts of our organism, and the poison ingested; and fifthly, that this specific action ceases on the elimination of the poison from the system. The first law is one almost universally acknowledged, and forms the basis of the remedial part of the physician's art; for, unless medicines had definite and specific actions, they would be valueless as remedies. As instances, we may adduce hydrocyanic acid, strychnia, castor oil, &c., which are severally known to produce, when taken into the fabric, certain determinate and invariable effects. It has long been admitted, that certain medicines—poisons—act more or less invariably on certain membranes or organs, or on certain sets of membranes or organs; but that the action depends on an affinity between the elementary tissues, or part of them, of the organ so acted on, and the poison itself is less universally allowed, although it is, nevertheless, equally as true. In poisons of this class are included antimony, arsenic, copper, strychnia, and many others. In proof of this position we may adduce the experiments of Blake, as quoted in the *British and Foreign Medico Chirurgical Review.* (July, 1848, p. 181-9.) He states, that his experiments warrant the following conclusions:—"The various substances—mineral medicines—may be arranged into groups according to the similarity or dissimilarity of their effects, each group being distinguished—by re-actions not to be found in any other class, whilst the reaction of each of its members closely resemble each other. The classes thus formed agree with those which are adopted by chemists in their arrangements of the different elements according to their isomorphous relations; and the only conclusion to be drawn from this interesting coincidence is, that the physiological action of these substances depends upon some property they possess in connexion with their isomorphous relations." Thus, potash and ammonia produce analogous effects; strontia, baryta, and lead; soda and silver; lime, magnesia, zinc, copper, manganese, nichel, and cadmium; platinum, palladium, iridium, and osmium; phosphorus, arsenic, and antimony; selenium and sulphur; and, lastly, chlorine, iodine, and bromine, form separate classes, each of which have the most striking analogy in their physiological actions. The metallic salts in general; the salts of potash and baryta, arsenic and phosphoric acids, agree in destroying the action of the heart; the greater part of the acids, and of the salts of silver increase its irritability. The dose, however, of these substances necessary to produce their specific effects vary very considerably.

The second law, that all poisons lie latent in the system for a definite but varying period of time, admits of but one exception, and that is more apparent than real, inasmuch as although comparatively the action is instantaneous, yet a certain short interval elapses between the taking of hydrocyanic acid and its effects. Narcotics, purgatives, diuretics, and other classes of medicines, all occupy a period of time of longer or of shorter duration, according to the condition of the patient as regards plethora, state of constitution, &c., and also according to the greater or lesser time ordinarily occupied by each medicine in producing its effects.

As an example of the third law, Dr. Williams adduces the action of oxalic acid. If this poison be taken in a small dose, death ordinarily results from inflammation of the stomach; whilst if the dose be very large, death may happen in a few minutes from the shock to the nervous system. We here have a good example of the modification induced by a variation in the dose: tartar emetic may be mentioned as another example.

The fourth law, that the specific action of poisons depends on the affinity existing between the liquids and solids of certain parts of our organism, and the poison injected, does not admit of so ready a proof as the other laws. The following considerations may be adduced in favour of it:—firstly, that the ordinary action of a medicine may be induced on the distant organ, or organs, whenever it finds its way into the fabric, whether it had been introduced by the stomach, or injected into the blood. The experiments of Dr. Blake, already related, afford strong confirmation of this statement. The well-known fact, that particular purgatives will act on definite parts of the alimentary canal, that diuretics act on the kidneys, mercury on the liver, iron on the blood, all prove the same. Additional proof is also afforded by particular poisons attacking only particular viscera or tissues; and by their being found in greater quantity in certain organs, or tissues, as copper in the lungs, arsenic in the liver, &c., and in certain secretions, as sulphuric acid in the urine.

The results of the disease caused by the introduction of the morbid poisons into the blood tend to the same end. Mr. Paget, in his Lecture on Nutrition, &c., (published in the *Medical Gazette*), adduces the Essays on Symmetrical Diseases, which were written by himself and Dr. Budd as evidence that all diseases in which the two corresponding portions of the opposite sides of the body are similarly diseased, depend on the circulation of a morbid material in the blood, and an identity of composition in the tissues affected. He then proves, that certain morbid poisons, or other morbid matters, have certain "seats of election." Thus the syphilitic poison attacks in some patients corresponding portions of the tibia and of the skull with great exactness. The pelves of two lions were exhibited, in which new osseous matter had been deposited, by a rheumatic disease, producing an irregular kind of patern, both sides being precisely alike, thus proving beyond a doubt that the specific action of the morbid poison must have resulted from some affinity between it and the tissues attacked.

That the specific action of the poison ceases on its elimination from the system, cannot be very readily determined, as we cannot easily ascertain when the whole of the poison has passed out. Perhaps the best and most certain method of determining this point, is to examine chemically the urine and other secretions—excretions—to ascertain

g a period the poison is passing off. But is has been, and may be readily done in e of mineral poisons, yet it cannot be applied to the class of morbid poisons, as we have no physical or chemical means of determining their existence. The only organic poison that we can prove to become mixed with the blood, and to pass out of it again—the amanita muscaria—affords very strong evidence of the truth of this law. The following quotation from Dr. Pereira's Materia Medica first edit., Vol. I., p. 15, supports this, "A man for example, may have intoxicated himself to-day by eating some of the fungus; by the next morning he will have slept himself sober; but by drinking teacupful of his urine he will become as powerfull intoxicated as on the preceding day." Can more powerful evidence be afforded of the entrance of the morbid poison into the blood, the circulation of it through the system, the production of its peculiar effects on the brain, the elimination of the poison through the agency of the kidney, and the consequent cessation of its specific action.

In opposition to this view of the subject, it may be objected that the specific effects of lead, or of arsenic, will frequently continue for weeks, or perhaps for months, after the poison was taken into the system, and that we have no right to assume that this action was caused by the actual presence of the poison. It has, however, been shown, that arsenic may continue to be excreted from the body for as long a period as five weeks after the dose was taken; and I knew of a person who excreted lead by his skin for more than three months after he had ceased to be exposed to the influence of the poison. Most, if not all of the specific effects of a morbid poison may apparently cease before the whole of the poison is eliminated from the system. Thus a person may infect another with the exanthematous disease from which he has suffered, after all the ordinary specific effects of the poison have ceased that is to say, after the eruptive, and sometimes even after the desquamative stage has passed by.

Dr. Williams further states, "that the general laws observable in the actions of morbid poisons are for the most part precisely similar to those which govern medicinal substances, or only differ in a few minor points. These poisons have their specific actions, their periods of latency, while their phenomena equally vary according to the dose, or the predisposition of the patient." That the poisons are specific is proved by the precision of their course, and of the pathological phenomena which each individually exhibit. Morbid poisons, also, have their periods of latency, the duration of the period varying in the different diseases induced by them. Thus, the poison of scarlet fever ordinarily lies latent from a few hours to ten days; of measles from ten to fourteen days; and of small-pox from sixteen to twenty days.

The chief distinctions between the morbid and the mineral poisons consist, first, in the power which the former have of increasing within the system to a comparatively indefinite extent; and, secondly, in their specific effects being independent of the amount of the virus absorbed, a small dose producing as certain and as severe effects as a large one. Many of them, also, are capable of infecting persons at considerable distances, and of exhausting the susceptibility of the membrane diseased to any future attack. These peculiarities are possessed by the virus of scarlet fever, and will, therefore, be briefly considered.

The theory of the increase of the virus of a morbid poison within the system was propounded by the ancient physicians; for instance, Hippocrates attributed the phenomena of fever to a morbid matter in the blood, which being *concocted* for some days, was rendered fit for expulsion from the body. This theory has been revived, and more philosophically explained by Liebig, who ascribes the peculiarities of this class of diseases to the fermentation of the morbid poison in the blood. Liebig's doctrine of fermentation is that ferment, or yeast, is nothing but vegetable fibrine, albumen, or casein, in a state of decomposition, with their particles in a state of intestine motion. This motion being communicated to the particles of the vegetable, or of the animal matters with which the ferment is in contact, will, other circumstances being favourable, communicate the same kind of intestine movement to them, and thus split up their particles into new and less complex compounds. The gluten, or other azotised matters in the fluid act, therefore, the part of fresh ferment. Liebig elsewhere states, that animal fibrine, albumen, or casein may act as a ferment as well as vegetable. The poison of scarlatina having passed into the blood in perhaps an almost unappreciable quantity, multiplies itself within the body in a manner analogous to a ferment, until the whole of the pabulum in the blood that enables it thus to multiply itself, is consumed. Should there be no pabulum in the blood, no reproduction of the poison could ensue, nor could any of the ordinary effects of scarlatina occur, unless the quantity of the virus absorbed was sufficiently great to attack any membrane that had not been previously affected, or in which the change previously made had been effaced by the tendency existing in all altered diseased tissues to revert to their normal state. The non-susceptibility of the patient to the subsequent action of the virus, is ordinarily attributed to this modification of the blood; but for reasons, to be hereafter stated, I do not consider this to be the sole cause of it. The second distinction between the mineral and vegetable and the morbid poisons, namely, that the effects of the latter do not depend to any great extent on the dose of the poison, follows as a necessary result of the preceding law; for, if the amount of the virus circulating in the blood is ordinarily in proportion to the quantity of matter in the blood fit for its reproduction, it follows necessarily that the resulting disease will depend, not so much on the dose of the poison, as on the amount of pabulum then existing in the blood for its increase.

Scarlet fever may, perhaps, be considered the most infectious of all the exanthemata, as it is contagious both by individuals and by fomites, and it is also infectious. The poison has been known to extend itself to a distance of above two hundred yards. This part of our subject has been discussed already, and may, therefore, be dismissed without further comment.

The great peculiarity of the exanthematous diseases of hooping-cough, and to a less extent of typhus, consists in the immunity that one attack affords against another to a part that has once been affected; and it becomes a matter for consideration to determine, if possible, the cause of this immunity, to ascertain the alterations in the organism affording it. Does it arise from a peculiar and definite alteration in the blood, or in the tissues, or in both? My own opinion, in opposition to that ordinarily entertained on the subject, is in favour of an alteration both in the blood and in the tissues.

It has already been shown, that the poison of the disease must increase within the system, and that this increase must depend on some peculiar action of the poison on the blood, most probably by a process analogous to that of fermentation, as described by Liebig.

This alteration having once been effected in the blood, ordinarily remains permanent; but, in some few instances, it becomes effaced, when the blood would admit of a similar change, if the individual again received any of the morbid poison. But it seems probable, that the blood might become charged with the morbid poison, by the absorption of a quantity at a time when the atmosphere was greatly loaded with it, as during the progress of an epidemic. Under these circumstances, it is most probable, that any membrane that had previously escaped might be attacked with the disease.

[To be continued.]

PRACTICAL OBSERVATIONS ON THE TREATMENT OF INSANITY.

By WILLIAM SMITH, M.R.C.S.L.
Formerly Resident Surgeon in the Lincoln Lunatic Asylum, and subsequently in the General Hospital at Lincoln.

In the first Number of the *Psychological Journal*, edited by Dr. Forbes Winslow, is a paper "On the Sedative Treatment of Insanity." Without wishing to detract in the slightest degree from the merits of Dr. Seymour, as an enlightened and skilful physician, or call in question his knowledge of mental pathology, I cannot help expressing an opinion, (founded on more than nine years' practical observation amongst insane persons,) that the so-called sedative system of treating the insane is not entitled to the high encomiums which Dr. Seymour and others have claimed for it.

During my official connexion with the Lincoln Asylum I had ample opportunities of testing the merits or demerits of the sedative plan; but more particularly so from the fact, that the late Dr. W. D. Cookson, (at that time one of the physicians,) at one period of his life warmly advocated their employment; and here, *in limine*, I would remark, that the exhibition of narcotics or sedatives, and the employment of mechanical restraint or seclusion, for the purpose, as some think, of subduing maniacal excitement or removing irritation, are much more intimately connected than many persons superficially acquainted with insanity would suppose. Now, believing (as all my experience goes to prove) that insanity is essentially a disease of accumulated excitability, a superfluity or excess of the *vis nervosa*, (call it by any name you please,) I cannot for the life of me conceive upon what physiological or philosophical principles those persons act who prescribe narcotics or sedatives, or employ mechanical restraint or seclusion, for the purpose of getting rid of this same pent-up, morbid irritability. If I might be allowed the use of a homely simile, I would compare an excited and furious lunatic to a monster railway engine, snorting and fuming at the railway-station just prior to its being despatched with a heavy luggage-train; what the safety-valve and the puffs of smoke are to the railway-monster, the restless mobility, great muscular activity, and the noisy vociferations are to the lunatic. The latter must get rid of his extra steam by some vent, and nature (if we will only use our eyes and ears) gives us very plain indication. If my theory be correct, what becomes of the principles of those who (at the very onset) administer narcotics and sedatives, tartar emetic, &c., &c., or tie down an excited lunatic in a crib, bedstead, or a filthy restraint-chair. We have had a fair stand-up fight with the advocates of mechanical restraint; and, though our numbers have been few, like the Spartans at Thermopylæ, we have achieved a glorious victory; the narcotic and sedative plan is merely an old enemy under a new guise; the principle is unsound, therefore inevitable defeat awaits it. I wish not, however, to be understood as proscribing the use of narcotics and sedatives altogether. I do not assert that they are "never necessary, never justifiable, and always injurious, in all cases of lunacy whatever." In puerperal mania, in mania arising from, or complicated with, intemperance, in cases where there may be great irritability of the nervous system, with feeble pulse, and great prostration of the vital powers, opium, or its preparations (as, under similar circumstances, the idea of lunacy apart,) would be our sheet anchor. Let every individual case of insanity be treated on its own merits. The great principles which guide us in the selection of remedies for diseases affecting other parts of the human frame are equally applicable here. I repudiate entirely (as most empirical) the idea of there being any specifics for insanity; in truth, there are none such. On being called to a case of mental alienation, our duty is carefully to inquire into the condition of the various important organs, the stomach, the uterus, liver, &c., and the state of the secretions; and should there appear no clear indications for medical treatment, it is much more prudent, as well as more philosophical, to do nothing more than to order medicaments, without any definite object, which I hold to be striking a blow in the dark. This doctrine may not suit everybody. Young practitioners, on first being launched on to the troubled waters of medical practice, place wondrous faith in the efficacy of *medicamenta*. But ten or fifteen years' extensive observation of disease, dispels the illusion. What I conceive to be points of great beauty in Lincoln management, have been

furiously attacked by the Lunacy Commissioners. However, *de gustibus non est disputandum*, there is no disputing against "hobby horses," as Yorick has it. I am quite ready to admit, that, under the old *régime* of mad-houses, medical treatment was most scandalously neglected; but, judging from the "Further Report of the Commissioners in Lunacy to the Lord Chancellor, 1847," and the prolix "Essays on Mental Pathology," furnished by certain youthful aspirants for fame, we appear to be in danger of running foul on the opposite tack; and if all the medicaments mentioned in that "Report" have been really administered, (I say) may the Lord protect the "*ilia dura*" *lunaticorum*.

As a slight specimen of the truly practical and untheoretical character of some of these juvenile specimens of mental pathology, I take leave to quote from the aforesaid "Further Report," page 462:—"In melancholia and other forms of partial mania, it is probably that some portion only (and that circumscribed) of the cortical matter is diseased, and, from its undue irritability, not only distorts the impressions conveyed," &c. Now, what does this *ingenuus puer* mean by partial mania, and what probability is there that a piece of the cortical matter keeps up a piece of mania, and that the impressions on other parts are but feebly noticed? If this be not most unmitigated twaddle, what in the name of common-sense is it? However, this said learned Theban has (by his most erudite theories) got himself smuggled into a snug appointment in the Lincolnshire County Lunatic Asylum, now in course of erection, and that, too, without going through the ridiculous farce of a public competition for a public appointment! If the Commissioners of Lunacy are to exercise an influence in appointing future Superintendents of Public Lunatic Asylums, in the same manner as has been done in Lincolnshire, I know not what results may ensue. *Dii avertite omen.*

But to return to the subject of sedatives. My esteemed friend, F. D. Walsh, Esq., the Resident Surgeon of the Lincoln Asylum, in a most interesting letter, developing his views of insanity, remarks:—"If a patient is in such a state that he would run his head against a wall, seclusion would do him harm. I have found it the best practise in these cases to give them as much air and exercise as possible, keeping an attendant or two with them to keep them from injury. I never mind their dancing about, or their grotesque actions, for they will sleep better after these actions than after any opiate. The attendants are so aware of this, that when a man is restless in this Asylum, or sleepless and noisy at night, they are anxious to get him out (as they say) to let him run it off. I had one case secluded by Dr. Nicholson, under the pretence of putting him under medical treatment. He gave him, in less than twenty four hours, above two ounces of Battley's sedative solution without any other effect than increased excitement, till at length the case became what is called dancing mania; he began dancing and knocking his fists or his legs against the wall. (I was asked a few days before, by a German Physician, "Where would my non-restraint be in a case of dancing mania?" You shall see.) I ordered this man to be taken into an open gallery, and the violin to be played to him, and let him dance till he was tired; I then told him he had not had dancing enough, he had better have a race; I then took him into the grounds and raced with him; he then had his supper, and went to bed: he slept through the whole night—the first sleep he had during a fortnight. He had no mania the next morning, and got well from that day: has been discharged as recovered; and is now succeeding very well in his business. I think this case is remarkable, as showing the evils of seclusion in cases of mania; and from the benefits I have seen derived in this and similar cases by means of exercise, I feel convinced that the propensity for muscular exercise should be encouraged as one of the means established by nature for a recovery; more particularly, as I had a female in the house at the same time who was a similar case of mania, she was also put upon opium without effect; but the doctor, tiring of this, put her upon hyoscyamus, antimony, and finished with digitalis. She became emaciated under this treatment (well she might!) and though now she has recovered flesh, she has not recovered her intellect; she has been here two years, and appears an incurable case; I think she will never get well.

Dr. Charlesworth, the senior Physician of the Lincoln Asylum, whose whole life may almost be said to have been spent in the wards, or the Board-room of that Establishment, so deep an interest has he taken in its management, has no faith in narcotics or sedatives; and Dr. Elmhirst, who acted as Physician there for, I think, about fifteen years, does not advocate their employment. The only Physicians at Lincoln who have used them to any extent were the late Dr. W. D. Cookson, and Dr. Nicholson, who was for a short period Junior Physician to the Asylum; but, in both instances, the practice was signally unsuccessful, and the failures are fully recorded in the official books of the establishment; in fact, Mr. Walsh, the present Surgeon, from seeing the untoward results of Dr. Nicholson's practice, is more opposed to sedatives than myself.

Dr. George Burrows, whose "Commentaries on Insanity" I have read with much pleasure, speaks very guardedly as to the efficacy of narcotics. He says, p. 610:—"Of all the remedies prescribed for insanity, except blood-letting, there is none on which there is such a diversity of opinion as on the efficacy of narcotics. Ounsalon and Morgagni condemned narcotics as injurious to the insane. Regimen, labour, and exercise, some say, are the only remedies for sleeplessness. Many proscribe narcotics altogether, others recommend them in small, and others, again, in astounding doses. Their effects are as variously described. These contradictions, I apprehend, arise chiefly from ignorance of the distinct stages which insanity assumes, or from not noting the exact state of the patient when the narcotic was given. Maniacs will generally bear large quantities of opium and other sedatives better than they will support remedies which weaken the vital powers. But opium, when the excitation is great, in a full and strong habit, aggravates; when the excitation is moderated by previous depletion, or the habit is reduced by long-continued mania, stimulants like opium, wine, porter, &c., tranquillize and prove soporifics. If, therefore, an opiate be given in the early stage of an attack of mania, before the bloodvessels and *primæ viæ* are unloaded, it may force sleep by increasing sanguineous congestion, and compressing the brain; but it will certainly excite and aggravate all the symptoms. In fact, the system must be emptied, and somewhat lowered, before opiates should be administered."

The late Sir W. C. Ellis, in his "Treatise on Insanity," p. 172, observes:—"To allay irritation is, evidently, the great desideratum; but, as it is well known that there are peculiar idiosyncrasies in almost every constitution, so it will be evident that the means must be varied as we find them to exist. The same medicine which will allay it in one, will not in another, but, on the contrary, increase it. This is particularly the case with opium, which is rarely found admissible in insanity. It more frequently creates heat, and general febrile action, than procures sleep. In the first stages of the disease we ought, if possible, to avoid the use of narcotic medicines; and endeavour to procure sleep by allaying irritation, in the method above pointed out. I wish particularly to press this, because much has been said by some authors on the necessity of procuring sleep by any means, and of keeping up the strength of the constitution with hearty suppers, porter, and other stimulants."

Haslam, in his "Observations on Madness and Melancholy," remarks, pp. 339, 340:—"Respecting opium, it may be observed, that whenever it has been exhibited during a violent paroxysm, it has hardly ever procured sleep; but, on the contrary, has rendered those who have taken it much more furious. And where it has for a short time produced rest, the patient has, after its operation, awaked in a state of increased violence. Many of the tribe of narcotic poisons have been recommended for the cure of madness; but my own experience of those remedies is very limited, nor is it my intention to make further trials."

But, to come to a more recent authority, Dr. Conolly, the enlightened and humane physician of the Hanwell Asylum, (whose extensive experience in insanity must equal that of any physician of the present day,) does not appear to entertain any very exalted notions of the efficacy of sedatives. In the "Further Report," before named, p. 444, he thus tersely describes the practise pursued at Hanwell:—"A kind and soothing reception, immediate removal of restraints, a warm bath, clean clothing, comfortable food, encouraging words, a medical treatment first directed to any manifest bodily disease which may occasion the cerebral disturbance, as of the uterus, stomach, &c., or the general loss of strength; and if such disease or debility is not manifest, attempts to allay the irritation of the brain more directly, by leeches occasionally applied to the head; gentle aperients, moderate doses of tartarised antimony, sometimes combined with sedatives; cold applications to the head, blisters behind the neck, shaving the head, and friction of the scalp, with the tartarised antimony, the warm-bath, or in violent cases, a cold shower bath efficiently applied. Tranquillity, occasional exercise in the open air; exercise and occupation in chronic cases, cleanliness, order, good diet, attention to relieve heat and thirst, particularly in the night; a careful avoidance of everything that can irritate the brain, including the avoidance of the strait-waistcoat, &c., &c. Antimony and all sedatives are of uncertain effect, and sometimes of none; *time* seeming alone to effect a cure, provided proper and constant care be taken of the patient."

The subject of narcotics and sedatives, (like every other important matter bearing upon the improved treatment of the insane,) has been repeatedly discussed in the valuable printed Reports of the Lincoln Asylum. On reference to the Nineteenth Report, p. 5, I find the following General Board order.—"That the practice of shaving the heads of lunatics, blood letting, the cold bath, baths above blood heat, the process of subduing violence by the use of tartarised antimony, or of narcotics; the practice of enforcing sleep by opiates and courses of drastic medicines are hereby interdicted, except in special cases, otherwise medically requiring the same."

This same disuse of sedatives or narcotics formed one item in the memorable controversy between the Lincoln Governors and two of Her Majesty's learned Commissioners in Lunacy; the former gentlemen, in their reply to the Commissioners, remark:—"When a person, not habituated to the treatment of lunacy, sees a restless patient, he naturally follows the first popular impulse of administering a narcotic; and it is obvious, that if the narcotic answered the end, such an easy remedy must long ago have been the settled recognised practice in such cases. The very contrary is the fact. It is settled, that narcotics must be used with the greatest caution; and it is curious, that in the case of M. B., referred to by the Commissioners, and affording them, as they suppose, grounds for complaint, that, 'no means were used for procuring sleep.' Under this alleged neglect, this same patient has rapidly and perfectly recovered, and is now discharged within two months of the date of her admission."

In the Twenty-third Annual Report of the Lincoln Asylum, pages 4 and 5, I find the following:—"'Resolved, that the junior physician, having declared his determination to disobey the rules and laws of the establishment, and so to place the house-surgeon and other officers in the position of active parties to a disobedience of the rules and orders of the house, it has become necessary to adopt measures for sustaining the authority of the Boards.

"Resolved and ordered, 'that no preparation containing morphine, or narcotine, fox-glove, or strychnine, nor any fermented drink, be employed by the house-surgeon, under any order of the junior physician, without a consultation with, and the approbation of, one at least of the senior physicians; but, that the house-surgeon, on any emer-

gency seeming to require their use, proceed on his own responsibility, under Rule 11, sect. vii."

I feel considerable delicacy in quoting the above extract, showing as it does, the miserable state of disorganisation into which any public medical charity may be precipitated by party squabbles and differences of opinion amongst the members of its Medical staff;—it teaches us (at the same time) a practical lesson, to place the government of public Medical charities in as few hands as possible;—it shows the palpable absurdity and mischievous consequences resulting from a numerous, unpaid, (almost irresponsible,) and non-resident staff of physicians and surgeons; whilst the resident surgeon, who alone can know the intimate and ever-varying condition of the patients, is virtually restricted to the subordinate office of dispenser, and confined to the exhibition of the infallible remedy, (at Lincoln,) salts and senna. May the petty feuds and angry altercations, which, for more than twenty years, have disgraced the Board-room and Medical staff of the Lincoln Asylum, and sullied its otherwise bright laurels, prove a warning beacon to other establishments; and when its present despotic and fast-crumbling form of government, shall sink into a fallen ruin, may it, phœnix-like, rise from its former ashes, and, under a more honourable principled, and purer-minded body of rulers, furnish a bright example to surrounding institutions!

Belper, South Derbyshire, Aug. 18, 1849.

PROGRESS OF MEDICAL SCIENCE.

FRANCE.

[From our own Correspondent.]

We have still the same number of cholera cases daily, or perhaps a slight increase; but, what is more remarkable, is the fact, that the disease attacks and carries off a comparatively great number of persons amongst the middle and upper classes of society. Within the last week, this has been particularly the case. Amongst the victims may be mentioned M. Robert, Member of the Legislative Assembly; M. Mourdhon, Director of the Orleans and Central Railways, who was buried this day; one of our first miniature painters, and many others. The Hospital of Incurables, in the Faubourg St. Martin, which had so long escaped, has recently been attacked; and, although the mortality is far from being excessive amongst the inmates of the Asylum, no less than five of the Medical assistants have already fallen victims. At Bordeaux, a very severe epidemic of dysentery accompanies the cholera; and, although not so fatal, its ravages are greater from the greater number of individuals attacked. Children and infants are the principal sufferers. The mortality from cholera at Bordeaux does not exceed 8 or 9 per day. Here at Paris it still carries off from 35 to 40 persons daily. Our Medical men seem to be more backward than even the English in the way of treatment, and the Academy of Medicine seems chiefly occupied with the examination of quack remedies for the disease, all of which are, of course, pitilessly rejected.

ABOLITION OF QUARANTINE.

The French Government, after many years of hesitation, has at length consented to abandon the absurd and injurious system of quarantine, which nothing but gross ignorance, or rather, perhaps, the self-interestedness of a few individuals, continued to maintain.

Henceforward all sailing vessels from Turkey, Egypt, or Tripoli, with clean bills of health, will be admitted at once into the French ports, if there be no suspicious circumstances to justify a delay.

Steamers, also, will be admitted without quarantine, if eight clear days have elapsed since their departure from any of the above-named countries, and if they carry a medical officer on board. When this latter condition has not been complied with, they will be subject to a quarantine of three days.

These regulations are founded on two main points, which the Government says have been fully established. In the first place, the incubation of the plague never exceeds eight days; and in the second, it has been shown by the French Medical Officers in Egypt, that plague has not appeared in that country since the year 1844. This latter fact is a triumph, as it is a proof of the progress of civilization. It is consoling to think that we can exterminate the disease, though we may not be able to cure it.

INCREASE OF THE FIBRINE OF THE BLOOD BY HEAT.

M. Marchal endeavours to find an explanation of the fact well known to all pathologists, that inflammation increases the quantity of fibrine contained in the blood. Rasori, it is true, attributed the increase to augmentation of the temperature and the increased movement consequent thereon; but, Rasori does not seem to have supported his theory by any experiments. M. Marchal has supplied the latter, which prove, so far as things go, the influence exercised by increased temperature.

Two porcelain cups received the same quantities of blood from the same individual. But one cup was enclosed in water of 60° centigrade; the other surrounded by a frigorific mixture. Coagulation was allowed to take place, and the fibrine from the two specimens weighed. The blood coagulated under the influence of heat always showed a great excess of fibrine, varying from 23 to 37 parts in 1000.

M. Marchal is inclined to think that the increase of fibrine takes place at the expense of the albumen.

ANIMAL MAGNETISM.

In a former letter I noticed some curious experiments made by M. Ducros, on the influence which the proximity of the hand exercises on a magnetic needle, making it deviate from 5 to 20 degrees.

These experiments have been repeated by M. Despretz, who acknowledges the fact of deviation, but asserts, and with apparent truth, that the phenomenon depends on heat, not electricity. In fact, any heated substance produces the same deviation; a bit of wax candle, a hot coal, &c.; sheet of thin polished tin, placed between the hand and the instrument will prevent the influence of the former, because it reflects the rays of heat; but it will not intercept the influence of an electric needle.

On the other hand, M. Pouillet contends, even more peremptorily, that the phenomena alluded to depend on certain currents of air developed under the influence of cold or warm bodies, and manifesting themselves even in the most perfect vacuum that we can produce. M. Pouillet assures us that this conclusion was clearly demonstrated so far back as the year 1829, and was rather severe on M. Despretz at the last meeting of the Institute; but M. Despretz is equally confident in the correctness of his explanation. Chemists, as well as doctors, often disagree.

UMBILICAL HERNIA—SUBCUTANEOUS OPERATION.

At the last meeting of the Institute M. Cardon related a case of this kind, which seems worthy of notice:—

"In October, 1845," says M. Cardon, "I saw a boy, eight years of age, labouring under inguinal hernia. The sac was extremely large, and descended nearly down to the middle of the thigh. As subcutaneous operations were all the fashion at that time, I resolved on applying the system to the case before me. Having opened the sac without any difficulty, I passed up a canula to the neck of the sac, and then made several scratches in the serous membrane at this point: in fact, they might be called incisions. The neck of the sac was now compressed by a bandage, under the idea that the wounded serous surface would inflame and unite. The inflammation which supervened was slight; the little patient, however, was kept in bed for six weeks, and watched with great care, so as never even to sit up. During eighteen months the child continued to wear a bandage; it was then removed, and the hernia has not re-appeared. The sac appears to have been absorbed."

M. Cardon asks, "Is this an operation which we could apply with prudence to congenital hernias, or which might be applicable to adults?" And he answers in the negative,—a judgment with which most surgeons will probably agree.

M. Velpeau, through whom the above case was communicated to the Academy of Sciences, mentioned, that he had once performed a similar operation on an adult. It was not successful; but, on the other had, was not followed by an accident.

FOREIGN BODY IN THE RECTUM.

M. Velpeau likewise related at the last meeting of the Academy of Medicine, a curious case of this kind which had presented itself to him in the morning. A man was admitted into the hospital with a tumour, which projected under the false ribs on the right side. It was easy to trace the form of the tumour through the walls of the abdomen, and the patient confessed that it was produced by a long bottle of *Eau de Cologne*, which he had introduced into the rectum. Although the story appeared so extraordinary, it turned out to be true; for the neck of the bottle was easily felt on passing up the finger; it was then seized, and the whole bottle extracted with facility. It was 28 centimetres in length, and as the foreign body disappeared, so did the tumour of the side; in fact, it was impossible to doubt that the tumour depended on the projection of the bottle. The patient felt no inconvenience after the extraction of the substance; but it seems strange that any inflexible body could penetrate so far, without producing any lesion whatever.

EPIDEMIC CEREBRO-SPINAL MENINGITIS.

This dreadful malady, which prevailed towards the end of 1848 and the commencement of 1849, at Petit-Bourg, is carefully described in a memoir presented some time back by Dr. Ferrus to the Academy of Medicine. Unlike preceding epidemics, this one attacked children.

The symptoms are extremely well-marked and constant. The disease always commenced with a violent rigor, followed by vomiting for some hours, and then intense headache. In all the cases, excessive sensibility of the skin existed along the whole of the spinal column, and particularly at its lower part. All the patients, likewise, presented more or less rigidity of the cervical column, almost amounting to opisthotonos in some cases. (The same stiffness and rigidity are a frequent symptom in the ordinary hydrocephalus of children.) The limbs were often agitated by convulsive movements, and contraction of the extremities existed in all the cases except one.

The state of the pupil was not constant, being sometimes dilated, sometimes contracted, or alternately so. The delirium was more or less violent in all cases except one; but coma was seldom profound, and in two cases it was absent.

The pulse was ordinarily, and during the whole course of the malady, depressed, slightly accelerated, or even slower than natural; seldom above 100, never beyond 104.

Of the seven cases described by Dr. Ferrus, two ended fatally in six days; two in four days; one in a few hours; one favourably, in fifteen days; and one little patient, after having remained four months in a complete state of idiotcy, recovered completely.

Post-mortem examination revealed the existence of lesions, which might easily be deduced from the symptoms. The principal were, inflammatory injection of the meninges, chiefly remarkable; first, along the fissure of Sylvius and on the pons varolii; and, secondly, along the spinal marrow, and particularly at its lower part. In three cases there was abundant suppuration of the sub-arachnoid cellular tissue; and in one of these the pus had followed the sheath of the optic nerve into the interior of the eye-ball. The quantity of pus underneath the arachnoid of the spinal marrow was very considerable. In one case, which terminated fatally, there was nothing more than simple injection of the membranes. The cerebro-spinal substance was healthy.

One case was remarkable from its similarity to typhoid fever. The deep stupor, the dark state of the tongue and teeth, and the delirium might

have led the Medical man into error; but, on the other hand, the throwing back of the head, with stiffness of the neck, contracture of the limbs, and absence of diarrhea, could not deceive him.

The treatment employed was energetic, though unavailing.

An epidemic of the same kind prevailed some years ago amongst the garrison of Strasbourg, and has been well described by Dr. Tourdes. The above notice may afford a means of comparing its symptoms with those of ordinary tubercular meningitis. Rigors and furious delirium are the chief symptoms in which the epidemic differs from the tubercular form. The effusion of pus underneath the arachnoid, and especially over the spinal marrow, is its main pathological lesion.

GERMANY.

STATE OF THE OVARY DURING MENSTRUATION.

Janzer, of Philipsburg, has given, in the "Heidelberg Annalen," No. 13, 1848, an account of the condition of the ovaria in a young woman, who was murdered four days after menstruation had ceased.

On the surface of the left ovary was a dark red spot, rendering the peritoneum vascular in this place, and presenting a minute aperture, with tolerably smooth margins. The spot consisted of a globular, very red mass, which was imbedded in the ovary, and separated from it by a thin yellow covering. The red mass, after washing, consisted of many layers of smooth, broad fibres, which united with each other in an arched form; and the yellow layer included besides some fat not contained in cells. Close to the yellow mass was a mulberry-shaped yellow substance imbedded in the substance of the ovary; it consisted of areolar tissue with a whitish amorphous fat in its meshes.

The right ovary contained two yellow bodies precisely similar to the above.

The Fallopian tubes were swollen at their trumpet shaped extremities, but did not embrace the ovaries. The least pressure upon this part of the tubes forced out a whitish substance of the consistence of pus which consisted altogether of roundish ciliated epithelium; no ovulum could anywhere be found.

The uterus was more vascular than usual. Its mucous membrane and glands seemed also more developed.

The author believes an ovulum to have escaped from the left ovary during menstruation; confirming Bischoff's theory of this process.

DEATH FROM A HUMAN BITE.

A police-sergeant, in the exercise of his duty, was bitten by a drunkard on the first joint of the thumb of the right hand. He had previously enjoyed excellent health. The wound healed in seven or eight days. On the third day after, and at nearly the same period of the day, convulsions came on, beginning at the seat of the injury, as a numbness and stiffness. The convulsions were accompanied with loss of consciousness, being thus essentially epileptic. He was treated by bleeding and purgatives. With varying exacerbations and remissions, mostly of a few days, they recurred, and in about three months the patient died apparently of exhaustion.

The main appearances were of purulent infiltration and softening of both hemispheres above the lateral ventricles. The membranes were thickened and vascular.

At a spot outside the skull, on the upper part of the occipital bone, the soft parts were thickened and infiltrated. The spinal cord was soft, but no clear evidences of disease beyond this. Nothing abnormal of note was found in the nerves of the limb, nor in the rest of the body.—(*Caspar's Wochenschrift*, Mai 5, 1849.)

URIC ACID DIATHESIS.

J. F. H. Albers, of Bonn, (abridged in *Schmidt's Jahrbucher*. Jahrgung. Nov., 1849,) has contributed a paper on the uric diathesis, with separation of uric acid and the disease of fermenting urine. His main conclusion is, that in the fermenting urine the carbonate of ammonia is the result of a vital process, and not of a mere chemical decomposition. In support of this view, he adduces the fact, that in urine which contains pus or fibrine, although all the elements for the formation of carbonate of ammonia are present, (as in inflamed bladder, &c.,) yet, by decomposition without the bladder, this is only formed in very small quantity, the ammoniacal phosphate of magnesia being the chief result. The latter product—at least its phosphate of magnesia, is believed by others to be derived from the fibrine, while the ammonia is as essentially developed by the nitrogen of the decomposing urea and uric acid.

OBLITERATION OF ANEURISMS AND VARICES.

Dr. Giuseppe, secondi of Milan, has proposed a new method of obliterating aneurisms and varices. He thrusts a trocar into the vessel, previously laid bare, if necessary, and on withdrawing the stilet, inserts a cylinder of waxed sponge through the canula into the vessel. The swelling of this and the coagulation of the blood effects the obliteration of the vessel.

The Author states the advantages of the operation to be the ease of its performance, security against secondary hæmorrhage, greater length and duration of the clot, and less secondary inflammation. In the case of veins, the advantage of a puncture over ligature and excision he regards as self-evident.

His experiments on animals are stated to support his conclusions.

But, it may be doubted, whether any of these advantages obtain in reality; and the comparative immunity of animals from secondary inflammation renders it unwise to lay any stress on the results. —*Schmidt's Jahrbucher*, p. 339.

MECHANICAL LEECHES.

These are mostly modifications of a small scarifying apparatus to which a suctorial portion is attached, either as a cupping-glass, or connected with an air-pump.

BAPTISM BEFORE BIRTH.

Dr. Salomon, of Hildesheim, narrates a strange case. The child of a Roman Catholic was half delivered, only the head and arm remaining in the uterus, when the midwife asked and obtained permission to baptize, on account of the danger of its death. Instead of the necessary few drops, she suddenly dashed a handful of cold water on the child's posteriors. It moved violently, excited a strong uterine contraction, and was expelled dead: all endeavours to resuscitation were fruitless. The story forms an argument against baptism by injection, which even Mr. Shandy never anticipated: much less the doctors of the Sorbonne, whom he quotes.

TREATMENT OF GONNORRHŒA.

Eisenmann, Collin of Dresden, and Ficinus of the same place, speak very highly of the results obtained by an opiate wine of colchicum in gonorrhœa. The proportions are vini colchici, three fluid drachms to tinct. opii half a drachm. Some give it in increasing doses; others prescribe twenty drops twice daily. The cure is generally complete from the seventh to the fourteenth day.—*Caspar's Wochenschrift*, No. 35.

SCOTLAND.

[From our Edinburgh Correspondent.]

Cholera still prevails in Edinburgh, though but to a moderate extent. It cannot, however, be doubted any longer that the disease has distinctly re-visited the town and neighbourhood. Accordingly, the arrangements have been re-adopted which were made at the end of last year, for the reception of the patients into Cholera Hospitals, and for the report of the cases that daily occur. During the last several weeks straggling instances have been met with,—most of which were admitted into two wards of the Royal Infirmary appropriated to that purpose, on the understanding, that this arrangement was to be departed from if the attacks rose to any considerable amount; and as, in the week before the last, the cholera admissions exceeded twenty, the managers of the Infirmary wisely resolved to discontinue this accommodation, and to call on the parochial authorities to re-establish their Cholera Hospitals. The Fever Hospital in Surgeons'-square, which has not been required for fever for more than a year, was accordingly opened on the 27th of August, under the care of Dr. William Robertson, and now the admission of cholera cases into the Infirmary is refused. In this respect, we think the managers of the Infirmary have done exactly what prudence enjoined. They exclude cholera from the house, not for want of room,—not even from the fear of communication,—but out of regard to the fears or feelings of the rest of their patients. Cholera is a disease which carries so much terror along with it, that it should not be admitted, in a cholera season, within the walls of an ordinary Hospital. And this rule should be acted on altogether irrespectively of a belief in the infectious nature of cholera. It may be a fact, that those who have least intercourse with cholera patients are least likely to fall into the disease, even though there be no such thing as an infectious poison generated during its progress. This result may be the effect of moral or of physical causes; and, if the fact be as supposed, it is immaterial, in the mean time, whether one or either of these operates to its production. As long as there is a shadow of suspicion, that, by bringing cholera patients into a house, the inmates of that house have their chance diminished of escaping an attack of that disease, it is unwarrantable, nay, it is almost criminal, to introduce them. The matter in debate is not a dogmatical, but a practical question. It is not, how shall we think, but, how shall we act? What course of conduct is surest to exempt us from the risk of doing what may be injurious to our fellow-men? Let no more be supposed, than that, by non-intercourse with the affected, such a degree of firmness of mind is given to the timid as secures them, or some of them, against the disease. Is this nothing? If the life of even one timid person be lost by loose declamation against the belief that the disease may be contracted by intercourse with the sick, how shall a man justify to himself the indulgence in discourse fraught with such consequences? This is a point which we think is too generally misunderstood. It is assumed, that nothing but a poison generated in the living system by morbid action can be the means of spreading a disease among those who have intercourse with cholera patients. Such an assumption implies a second assumption, namely, that the etiology of diseases is already an exhausted subject. No reasonable doubt can be entertained, that hooping cough spreads by communication; yet the evidence of the generation of a communicable poison in that disease is at best problematical. No one doubts, that there is a tribe of spasmodic diseases which extend from one individual to another, and even at once to a multitude. Will any one venture to affirm the impossibility of cholera being propagated, in some instances, in an analogous manner. That many will at once cry out on the absurdity of such a suggestion, we are well aware. We content ourselves with replying, that the laugh raised against this idea proceeds on a presumption of knowledge which does not exist. Let us, then, lay aside dogmatism, and the belief that cholera must necessarily be amenable to principles supposed to be established in regard to other diseases, and act wisely on a practical view of the case. And that practical view, according to our way of thinking, is, that though cholera be not so certainly communicable as small pox, yet that those who mingle with cholera patients are more frequently attacked than those who adopt the rule of non-intercourse. The real question, then, at issue is, not whether cholera be propagated by a poison generated during the disease, but whether the state of the fact be or be not as just stated, namely, that non intercourse is the means of protecting some from the onset of the disease. The only practical answer that can be made to this view of the matter

is, that the fear of receiving the disease by communication will prevent the sick from obtaining proper attention. But this idea is sufficiently obviated by our experience, that, under ordinary circumstances in this country, no such difficulty has arisen. To deny that the disease spreads by communication in the face of facts which daily satisfy the public of the contrary, has no other effect than to force people into an extreme opinion as to its communicability. To prevent exaggeration during an epidemic, the only safe plan is to tell the whole truth. And this applies to the reporting of the numbers daily attacked, as well as to the admission of its limited communicability.

It is a very short-sighted view, to consider the daily reports a means of intimidating the public mind so as to increase the number of victims. We may suppress exact reports, but can we suppress the penny-a-line accounts in the newspapers? Can we prevent timid people from mutually exaggerating each other's fears, by more and more wonderful tales of the ravages of the epidemic, the confident repetition of which at last subdues even the sensible. It is somewhat disgraceful to Edinburgh, as a seat of Medical science, that a majority of our Police Sanitary Committee, composed of Commissioners returned by popular election, should entertain views so narrow as to have resolved to offer their strenuous opposition to the daily reports of cholera cases. Fortunately, their assistance can be dispensed with. They may rest assured, that public rumour will far outrun the truth. At the commencement of cholera in Edinburgh, before confidence was established in the regular reports, all sorts of extravagances prevailed over the town as to the ravages of the disease and the conduct of Medical men, and the like tales have revived of late in the temporary absence of definite information. As a specimen, it was gravely announced in several inferior Edinburgh newspapers, and even got into some of the London journals, that a boy was taken to the Infirmary under cholera, and being supposed to be dead was carried to the dead-house, and left there for many hours till the attendants came to put the body in a coffin, when he was found to be alive. Popular rumour added what he saw in the dead-house during his stay there, namely, that a doctor came round and knocked on the head such of the unfortunates in the same predicament with himself as were foolish enough to show signs of life in his presence. Fortunately, the boy's name was given in the newspapers, so that it became easy, when the attention of the Hospital authorities was drawn to the rumour, to give an explicit contradiction of the whole fabrication. The boy was not even affected with cholera, being merely cold and wet from long exposure to a heavy rain, in a Temperance Society excursion.

Within these few days a rather unpleasant incident has occurred in connexion with a supposed case of cholera. A lady came from London to Edinburgh with the body of her daughter, cut off by some chronic disease, to have it buried in an Edinburgh cemetery. The lady is represented as having been in a feeble state of health on her arrival, and in a very desponding condition. On the evening before her daughter's funeral she was taken ill, and a highly respectable medical man was sent for from a neighbouring street. He appears to have looked on the case as one of a very serious character, and he saw her repeatedly before the next day at two o'clock, and even remained with her a considerable part of the night. At two o'clock he saw her for the last, being then obliged to go to pay a distant visit. After he left her she became much worse, and he was from home when sent for; two other medical men were summoned. When they arrived the patient was expiring, or already dead. They, trusting to the appearances of the dead body, and without waiting the return of the medical man in attendance, at first pronounced the case one of cholera, and one of them went straight and reported it as such at the College of Physicians. The medical man, at first in attendance, did not view the case as one of cholera. There had been constipation for ten days before the lady fell ill; the attack was diarrhœa, with enormous feculent evacuations, and great consequent sinking, from which she rallied under the use of restoratives, showing, according to his observation, none of the proper characteristics of cholera. The new attack, however, after he left her, the following day, speedily carried her off. There is but one point in this case on which it is easy to give an opinion. Whatever reason the last called in medical men had to consider the case as one of cholera, they fell into a breach of medical etiquette in pronouncing on the case, and reporting it as cholera, without first hearing what the medical men, in attendance from the first, had to say in support of his view, as gathered from his assiduous attention up to within an hour and a half of the patient's death. The circumstances of the case are, doubtless, somewhat equivocal. It would be unreasonable to insist on the two medical men who were present at the death giving up their opinion; but they should acknowledge that their example is not to be imitated in a like instance. They were, doubtless, taken by surprise, and did the thing inadvertently, as neither can be, in the least, suspected of the smallest inclination to slight the opinion of a medical brother, or to do anything offensive to his feelings. Fortunately, there can be no doubt that, as regards the treatment, this rapid case met with every justice.

On the 1st of October a new assistant-surgeon is to be appointed to the Royal Infirmary, the vacancy being created by the expiration of Professor Miller's period of duty as acting surgeon. As Professor of Surgery, Mr. Miller will remain an *ex officio* consulting surgeon. At the last election it created some surprise that Dr. Richard Mackenzie, though a very promising young surgeon, should have been appointed in preference to Mr. Goodsir, the well-known Professor of Anatomy. The reason, we believe, privately assigned by the managers for this preference, was that Mr. Goodsir was a new candidate, while Dr. Mackenzie had been a candidate on two previous occasions. This reason is not without force, but we think, the same may prove very embarassing to the Board on future occasions. Thus, how are they to shake off the pretensions of a candidate of doubtful fitness, who chooses to make repeated applications. We think the reason an unsafe one. Dr. Mackenzie would not have had long to wait, and the services of Mr. Goodsir would have been secured to the Infirmary. We trust Mr. Goodsir will accept the explanation given on the part of the management, though private, and come forward as a candidate on this occasion.

By inadvertence the name of Dr. Harvey, Lecturer on Practice of Medicine, King's College, Aberdeen, was omitted among those of the candidates for the Chair of Medicine in the University of St. Andrew's. Dr. Harvey's present position must give him a high place among the candidates. Some amusement has been created by a jocular announcement that Dr. Sharpey, who is just now in Edinburgh, had come from London to present himself as a candidate among the rest for St. Andrew's.

THE MEDICAL TIMES.

SATURDAY, SEPTEMBER 8, 1849.

It is the peculiarity of childhood, and of those earlier ages of society which represent the infancy of civilization, to behold only the present. Absorbed in the multitude of new objects presented to its sight, the child lives in an atmosphere of varied sensations, a life of impressions. Engaged in an hourly strife with nature, the existence of the savage is little more than one continuous action—a struggle for present subsistence. It would be well if this state of mind, which in these two instances seems scarcely a misfortune, much less a fault, were limited to them; but, unfortunately, it obtains in others whose views ought to be as far wider, as their actions should be on a larger scale. And, thus, now as heretofore, a large portion of mankind live only for the present moment, and are, in the language of the wise Greek, "αει παιδες"—eternally children.

Hence it becomes continually necessary, in treating of topics which are especially those of the present time, to take care that their history shall be borne in mind, not only in order to our avoidance of former errors, but also with a specific view of forming some conjectures respecting the future, conjectures which, if they cannot altogether guide our practice, may, at least, animate our hopes and increase our exertions.

The sanitary movement is essentially a modern one. Not but that former cities, and more ancient states, have availed themselves of drainage and cleanliness. But though little ought to be said by us in praise of our own times, we are justified in drawing a broad line of distinction between the motives, the acts, and the results of ancient and modern legislation on this head. Grecian taste on the one hand, or Roman luxury on the other, bear but a superficial resemblance to that union of science and philanthropy to which we may affiliate the modern measure. Nor is the offspring less unlike; for the present state of society—the distribution of wealth, and the annihilation of despotic power—both renders the task greater, and the means of executing it less.

But here our comparison ceases. The results are as yet at so great a distance, and the conditions so different, that all analogy fails definitely to point them out, and the constituents of the sanitary future, can be little more than surmised.

One main constituent will be the diminution of infection. Let any man contrast the liability of the affluent and the poor to the ordinary infectious disorders; and he can scarcely fail to perceive, that there is so vast a difference to the disadvantage of the latter class, that some essential to the progress by which disease impregnates the system is in their case greatly modified. It is not too much to assume, that much of this is extraneous to the system; and consists in increased proximity of the individual to the focus of disease, or, what is virtually the same thing, in the higher infective intensity of a stagnant and unchanged atmosphere.

But, another chief element will probably be the diminished susceptibility of the healthier individual to these, in common with the epidemic, disorders. Among the latter, the tremendous scourge which is now devastating this capital may well illustrate this position. In the main, its objects are the poor, the toil-worn, and the destitute; and even in those instances where, as lately, death has singled out loftier victims, and bereaved a Profession of of one of its highest ornaments, and most efficient members, it is not difficult to recognise the toils of large practice as forming a probable element of the attack, and making scientific, like poetical, skill

"Nurse the pinion that impels the steel."

These remarks have assumed a third effect of less important influence, namely, the effect which must follow the placing of the masses in better physiological conditions, and which operating

as a prophylactic of all diseases, may thus be best characterised as an improvement of health generally. And longevity, already increased, may be expected still more to increase, so that the extravagant benefits of the wished-for philosopher's stone may be more than obtained; the selfish eternity of one unsympathising existence being more than compensated by a fulness of years which thousands may hope to attain and share.

It may be thought a strange time to indulge in such anticipations, when an epidemic of unparalleled severity is amongst us, and setting at naught all precautions and treatment. But it is in the midst of despair that hope is most needed, as an incentive to exertion; and, despite the painful aspect of the present, history may teach us how far worse were the pestilences endured by our forefathers. While reflection, even on what we see around us, leaves us not without hope, that a more rational and less accidental purification from our physical sins against Nature may free us from their punishment, and conduct us, by a far easier path, and at a far swifter pace, to a condition as different from ours as ours is from theirs.

NUMERICAL REPORTS OF CHOLERA CASES.

We have frequently dwelt on the want of method manifested by the Members of our Profession in carrying on investigations to ascertain the value of the remedies proposed for the treatment of Cholera.

To lighten the labours of those who have but little time at their disposal, to direct those who are unacquainted with the importance of method in conducting their inquiries, and to let no one individual's experience, however small, be lost, we have drawn up and inserted the accompanying Table.

It will be observed, that the chief object we had in view, while framing this Table, was the practical one, of determining the effects of the remedies proposed for the treatment of the disease. In order to obtain unequivocal results on that head, it is absolutely necessary that some of the symptoms present in the cases treated should be stated: so that the mild cases may be separated from the severe, cavilling be avoided, and the all-important object—the real value of the drugs employed as curative agents—be duly estimated.

Those interested may obtain copies of the Table referred to, free of expense, by application at our Office, 147, Strand, London. We beg none to refrain from returning it to us, even though they have filled in but a single case. The great advantage of a numerical analysis is, that it enables the experience of one man to be added to that of another, not vaguely, but in a definite form.

As we have no desire to appropriate to ourselves the labours of others, we shall print the returns we receive, giving the names of the gentlemen making them, and subsequently, in a separate Table, imbody the results we may obtain.

As a guide to those not experienced in the numerical method of relating cases, and to illustrate the plan proposed, we have ourselves filled up the Table with an account of four cases.

[Specimen.]

Remarks relating to Locality, Sewerage, Ventilation, Excessive Crowding, Exposure to Contagion, Poverty, Intemperance, &c.
...ewerage ...d, ventilation ...ent; wife and tw... children ... same ro... sober.
Sewerage imperfect; room close, and contains four people; no contagion; intemperate.
...ewerage and ventilation good; easy circumstances; temperate; no contagion.
No sewerage; ventilation bad; extreme want; sober; wife died of cholera 2 days previously.

LONDON WATER AND THE CHOLERA.

Dr. Lloyd, in his speech last Thursday week, at the meeting of the South London Medical Society, attributed the occurrence of cholera in some places to the inhabitants drinking water impregnated with decomposing animal matter. This statement, we believe, is perfectly true, as the recent catastrophe at Wandsworth clearly proves. There is no doubt that wholesome diet and pure water are highly conducive to health; and oftentimes the Physician is baffled in his attempts to trace the origin of diseases, or to accomplish their cure, by overlooking some of the things classed by the ancient hygeists under the τα ἒξωθεν προσπιπτοντα.

In this great Metropolis the food we eat, and the water we drink, are grossly sophisticated. The shambles teem with unwholesome meat, which, by the craft of the butcher, is sold to the poor as cheap and wholesome food. The grocer finds it to his profit to vend for "genuine young Hyson" sloe leaves and raisin stalks; and the milkman aids in the work of destroying the health of the inhabitants of this city by selling for "genuine milk and cream," a vile mixture of sheep's brains, sugar of lead, and chalk. The artisan, moreover, drinks in his "London stout," copperas and cocculus indicus; in his gin, cayenne pepper and oil of vitriol; in his brandy, a fiery malt spirit, disguised with burnt sugar and different essential oils to give it a real cognac flavour; in his water a clarified infusion of decayed vegetables and human excretæ. As the water of London has been more especially charged with producing diseases, it is our intention to notice the manner in which that article is now supplied to the inhabitants of the Metropolis, and the means by which an abundant and pure fluid may be afforded them. This is one of those departments of hygiene deeply interesting to the Medical Profession, and which, well understood, may lead to important results in the controlling of epidemics and the treatment of diseases.

From the earliest times, London has been principally furnished with water from the Thames; a river which, from its magnitude, rapidity of current, and natural purity, was well adapted for all domestic uses. The conduits at Tyburn, constructed by the Corporation in the reign of Henry III., and maintained by a tax on foreign merchants, first supplied the City. Subsequently, other works were erected on different parts of the river, and Sir Hugh Middleton conceived and executed the project of conveying the waters of the Amwell and Chadwell, in Hertfordshire, to London, to meet the wants of an increasing population. Pumps, also, have been erected from time to time for this purpose; but still the grand supply is drawn from the Thames. In the early periods of metropolitan history the river water was well adapted for the use of the people, but, now that 150 common sewers are constantly discharging the excretæ of more than 2,000,000 of human beings into it, common sense teaches us that it is unfit for domestic purposes. Civilization has been very uncivil to Father Thames, for it has changed its once limpid current into a turbid stream, which, being agitated constantly by the paddle-wheels of numerous steam vessels, sends forth the most disgusting and dangerous exhalations.

The Companies which supply this water to the inhabitants of London use means to send it into the houses as clear as possible. Mere percolation, however, while it may remove insoluble substances, can never free the water from impurities held in solution.' Dr. Paris, we believe, stated on one occasion, before a Select Committee of the House of Commons, that the water, as supplied by the Companies, was exceedingly foul, that it was injurious to health, and that he had visited a family whose illness arose from drinking it. But even allowing for a moment that the impurities held in solution are small in amount, we do not see why people should be obliged continually to swallow homœopathic doses of filth; and if Hannemann's doctrines be true, then the most serious consequences will follow the use of such a contaminated fluid as that of the Thames. Further, it has been shown, that as water becomes increasingly impregnated with animal matter, so it possesses in a higher degree the power of dissolving the salts of lead. As the inhabitants of London, therefore, multiply, so will the danger to their health be increased. We caution our Professional brethren on this point; for, while the Thames water may not now exert an influence on the leaden pipes through which it is conveyed for domestic use, it may speedily do so, and thus produce as serious results as the poisoned water at Claremont House.

The wells from which the metropolitan pumps are supplied are found to contain much impure matter: hence resulted the catastrophe at Wandsworth; and this is not a solitary instance. It is rather curious that many of the public pumps are situated in close approximation to grave-yards. St. Bride's is under the burying-ground, and though the spring is celebrated for its sparkling clearness, it is not free from certain impurities.

Water, sophisticated as it is, and therefore productive oftentimes of disease, is supplied to the inhabitants at high prices and in limited quantities. Various measures have, in consequence, been proposed to remedy these evils. One man would have an immense tunnel running parallel to the Thames without communicating with it, to carry away all the sewage water, and thus restore the river to its original purity. Another would sink large tanks in the ground, to receive the excretæ; while a third proposes to dig Artesian wells in different parts of the town. This last project, while it does not interfere with a proper system of sewerage, has other important advantages. It would afford an abundant and pure supply of water, while it would break up the monopoly which several Companies at present possess.

The chalk basin, upon which London is built, is so shaped as to contain the superficial and tertiary deposits. These are composed of vegetable soils, gravel beds, clay and sand-beds of different kinds, which are succeeded by the great body of plastic, or London clay, cropping out to the surface, and which entirely separates all communication between the land-springs contained in these deposits and the chalk-springs below. Beneath the chalk formation is a large body of weald clay. It is stated, that from 1000 to 2000 square miles of the chalk formation crops out to the surface immediately around London. It is from this exposed surface that the water is derived, which is said to equal, upon every square mile, 3,208,228 hogsheads; or in 1000 square miles, 3,208,228,000 hogsheads; which would daily afford 27¼ gallons to every individual in a population of 2,000,000. Into this chalk formation, containing such an immense quantity of water, it is proposed to sink Artesian wells. The works in Orange-street derive their supplies from that source, and from experiments it has been proved, that 100 gallons per minute abstracted from the wells lowered the water, on an average, only 13 feet, at which level the spring constantly supplies that quantity. It is calculated, that a hundred wells of a given depth, would adequately supply all the inhabitants of London.

We hope that the time is not distant when some efficient means will be adopted to furnish the Metropolis with pure water, for it is remarkable, that those localities which have been most severely visited with Cholera are supplied from the Thames. If the present system is continued, sanitary reform will be incomplete.

MEDICAL REMUNERATION.

The manner in which the poor are cared for in this country may, in some degree, be estimated by the fact, that the Guardians of the City of London Union have just erected a house at Bow for their pauper population, capable of containing 1000 inmates, at the cost of 60,000*l*. This house is replete with every convenience; and contains beside, a ward called Probationary ward, into which every proposed inmate must first pass, be, as it may be termed, "purified;" and, before entering into the permanent establishment, undergo an examination by the Medical man; whose duties, our readers will observe, thus early commence. Next we remark, and this we do with much pleasure, that this building also contains a well fitted-up Dispensary, and a Fever Hospital and an Infirmary, calculated to admit 250 patients.

All honour to these Guardians for their arrangements and their munificence! The existence of such an establishment for the poor and the needy, who are "not always to be forgotten," is honourable to us as a people; but we are sorry we cannot stop here, and console ourselves with this pleasing reflection;—there remains yet another point, upon which we cannot award praise. For, after all this outlay, and these judicious preparations, comes the concluding and crowning act—the nomination and remuneration of the Medical Officer, upon whom the usefulness or uselessness of this liberal disbursement must entirely depend. There is a homely proverb, "spoiling the ship for a ha'porth of tar," which fitly illustrates the course we hear it is intended in the next step to pursue;—the gentleman whose duty it is to examine probationers, to prescribe and dispense for the sick, arising from 1000 paupers—who, be it remembered, must furnish a large proportion, from their age, poverty, and condition—deemed, as evinced by the preparations of the Guardians, liable to amount to one-fourth, or 250 patients—to insure a due performance of these duties, will our readers believe, it is proposed that this gentleman, a non-resident Practitioner, shall receive 150*l*. a year! We need not add another word on the subject; we appeal to the proverb.

IRISH MEDICAL CHARITIES.

The condition of the Medical Charities in Ireland, is a subject of real importance to the Profession in England and Scotland. The system of appointment in England and Ireland is essentially the same; the evils under which the Profession groans are alike in the two countries; and there is no knowing how soon this system and these evils may be extended to Scotland. It must be interesting, therefore, to the Profession in England, to sympathise with its brotherhood in a neighbouring land, going through that bitter ordeal, from whence it has not itself completely emerged as yet; and it may be profitable to the Medical men of Scotland to observe the difficulties they will have to encounter should the Poor-law system ever be introduced into their ancient kingdom. But, above all, is it important to watch the progress of Medical affairs in Ireland, because, as we will show further on, the degradation and injury which the Poor-law system is, admittedly, inflicting upon the Profession, are not necessary adjuncts to that system; but that they are, on the contrary, the results of an arranged and central policy, which has been brought to bear with iron sternness on the fortunes of our Profession. We make this statement deliberately and advisedly; and we feel persuaded, that the more our readers reflect on the changes which have taken place in the condition of Medical Men during the last twenty years, the more they will become convinced, that there is such an inimical and secret policy at work. In this country it has been so long in operation, and its springs are so well covered, that Medical men are apt to ascribe the stinginess and contumely with which they are too frequently treated, to the faults of Poor-law Guardians, or of Medical men themselves. No doubt much is to be attributed to the ill-judged economy of Boards of Guardians, and the dishonourable rivalry of the unprincipled; but the history of the Poor-law in Ireland teaches us, that there is a deep and constant, although silent, current flowing, which carries along this economy and rivalry as the ostensible things upon its surface, but which is the result of a design; that, however apparently plausible in its objects, is not the less most obnoxious to the best interests of the Profession to which we belong.

Before the passing of the Irish Poor-law Act, the relief of the sick poor was effected principally by means of county infirmaries, fever hospitals, and district dispensaries. The funds for the support of these Institutions were procured, partly by subscription, and partly by grants from the county cess. As soon as the Poor-law Act came into operation, it was manifest to every reflecting person, that the old mode of Medical relief could not continue for many years. According as compulsory rates for the support of the destitute became frequent and burdensome, voluntary subscriptions to Medical Charities diminished in number and amount; and, at length, it became evident,

that if Medical relief should be continued to the sick-poor, the Institutions for the purpose must be supported by compulsory taxation. To meet this difficulty, the Legislature has gradually, by a series of measures, been engaged in drawing, over all the Medical Institutions of the country, the net of the Poor-law system; and it now appears inevitable, but that in a few years, all Medical relief will, in Ireland, be doled out at the hands of Poor law officials.

Now, we must regret, that this confusion of Medical charity and support of the destitute should have taken place. Every existing barrier between laborious poverty and helpless pauperism ought, we conceive, to be sedulously maintained. From whatever cause it may arise, the working classes do not at present consider it, in general, a degradation to accept relief in a hospital; and it is well that they have this feeling. Many an industrious artisan is prevented from sinking into hopeless poverty, by availing, for himself or for some member of his family, the temporary assistance afforded by a charitable Hospital or Dispensary. We do not deny, but that if the removeable causes of disease were met by appropriate sanitary legislation, that a much less amount of charitable assistance would be required, from the diminution of sickness amongst the poor; but, as long as epidemics and scrofulous diseases are fostered by defective arrangements in our cities, so long will Hospitals and Dispensaries be required to stem the tide of pauperism.

The Fever Act of 1846-47, placed the appointment of Medical Officers, and the determination of their salaries, in the hands of the Irish Central Board of Health. To be sure, the remuneration of Professional services was stated, in the Act, to be at the disposal of the Lords of the Treasury; but it was all along obvious that the Board of Health were the real actors in the scene. It must be in the recollection of our readers, the result of this arrangement. The Irish Board of Health published a tariff signifying its estimate of the value of Professional labour. It offered a reward of "five shillings per day," to use its own elegant phraseology, for attendance, by a resident Physician or Surgeon, on a Hospital or Dispensary; and one guinea a day to a non-resident sent to any particular district for similar services; the payment, in either case, to continue for the number of days that the Medical attendant was engaged in actual duty. Twelve hundred Irish Practitioners memorialised the Lord-Lieutenant against the indignity of this tariff. They were coldly repulsed. Intimidation was proffered towards some of the first men in the Irish metropolis, if they should offer the slightest obstruction to the successful prostration of their Profession, and promises of ulterior advantages were held out to those who, by their example, would assist the authorities in this grand effort, to cheapen Irish doctors. The Medical Periodicals of the time teemed with relations of these facts; and Dr. Graves, of Dublin, has placed on permanent record the chicanery which was had recourse to, for carrying out the views of the Board of Health. But, can we suppose, that the Board of Health, composed as it was of Medical Men, some of them of eminent station, would have subjected themselves to the disaffection of their professional brethren and would have run the gauntlet of general odium, without some particular reason. There cannot be a doubt, but that in the whole of their proceedings on that occasion, they acted according to the expressed wishes of those who appointed them. We can imagine those in authority intimating a desire that medical attendance should be obtained for the poor at the very cheapest rate. We can imagine courtiership prevailing over professional *esprit* and in this way only can we explain, and even so scarcely palliate, the conduct of the Irish Board of Health. From all this, however, we get an instructive lesson, which teaches us that statesmen are not our friends; that, on the contrary, their policy leads them to depreciate medical services; and, moreover, we are hereby taught, that whatever injustice or injury may be conceived against us, fitting agents will be found to perform, even amongst those whose position and relations ought to bind most intimately with our interests.

The process of lowering the Profession in Ireland, having been once commenced by the Board of Health, it was apparently thought that other agencies might be advantageously employed for completing the work. Therefore the Fever and Epidemic Act of this year bestows the power of appointing, and fixing the salaries of medical attendants on the Boards of Guardians. We have already stated our belief, that the degradation and injury inflicted on the Medical Profession, under the Poor-law system, is not necessarily inherent in that system. The Dublin Boards of guardians had originally some respect for medical services. They fixed the salaries of their first physicians and surgeons at 100*l.* per annum each; and, although, be it remarked, at the command of the Poor-law Commissioners, this salary was, at the time, lowered to 80*l.* per annum; it was subsequently, and after a contest between the Guardians and Commissioners, raised to the sum originally contemplated. We are aware of other instances in which Boards of Guardians have acted with equal liberality; so that it seems very likely that, if the Guardians had been left to themselves, they would have awarded adequate compensation for temporary and arduous medical services. They must have known, as men of business, that they ought not to expect Medical men of character or position, to undertake onerous duties for a few weeks, at the same pecuniary rate as if appointed for a permanency. But they were not left to themselves. The Government having got a Board of Health, composed of eminent Medical men, to announce that five shillings per day was sufficient remuneration for a daily attendance of several hours' duration, what were non-professional persons to suppose, but that this sum was a perfectly adequate compensation? We need not speculate on the results, however, for they have already been fulfilled. The Board of Health announced, that five shillings a day was sufficient for some hours of medical attendance; the Guardians have bettered these instructions, for they insist on their officers devoting their whole time, day and night, not in hospitals, but in attendance on the poor in their own dwellings, for the magnificent honorarium of six shillings per diem. But it is necessary that we should place on record the details of this transaction.

Upon the approach of the "prevailing epidemic," as it is gracefully termed in the newspapers, the South Dublin Board of Guardians commenced preparations for diminishing its dreaded virulence. At the suggestion of the Dublin Sanitary Association, hospitals were opened, and Medical men appointed for their superintendence. The general feeling was, that Cholera could not be advantageously treated in the dwellings of the poor, and it was, therefore, contemplated that all cases of the established disease should immediately be accommodated in hospitals. District Inspectors were likewise appointed to examine reported cases at their own homes, so as to ascertain whether they were fit for admission into hospitals; or to prescribe for such as appeared to labour under mere premonitory symptoms, or ordinary diarrhœa. The Hospital Physicians were given a guinea a day, but the duties of the District Inspectors being considered to be comparatively light, a remuneration of two guineas a week was proffered to them. Under these circumstances, eight District-Inspectors were appointed, who performed their duties in a manner highly praiseworthy, and, indeed, went beyond the terms of their contract, often treating patients in their own dwellings under circumstances where they could not be advantageously sent to hospital. By-and-bye, an unlooked-for change took place in the temper of the people; the hospitals began to be regarded with suspicion and alarm; and a marked repugnance was displayed towards entering them. The duties of the inspecting physicians became, on this account, enormously increased; their whole time became occupied in ministering to a class of advanced cases, whose treatment by them was not originally contemplated. Still, as long as they were left to suppose that their services were appreciated, as being rendered voluntarily in the cause of humanity, and not as the mere earnings of their hire, they never grumbled. But they were not permitted to remain in this state of blissful ignorance. There is, too, generally amongst every large body of men, whether it be a senate, a Railway Company, or a Board of Guardians, some thankless busybody, who, to show his own importance, will meddle in that which he does not understand, and probe those feelings to the quick which he cannot appreciate. Some such individual raised the veil before the Medical Inspectors of the South Dublin Union, and told them they deserved no credit for their laborious and most charitable services; that they were well paid for whatever they were doing. The Medical Inspectors were gentlemen; they were naturally indignant at this rude and uncourteous language; and they at once and unanimously stated, that although willing to go on as they had been doing, and give their unbought aid, ungrudgingly, to their fellow-creatures in distress, they owed it to the interests of their professional brethren to repudiate the statement, that they were bound to devote their whole time under the conditions upon which they

were appointed; and they added, that if the Guardians persisted in considering them as acting as their officers, when engaged in the treatment of cases of advanced cholera in private dwellings, they must either remunerate them in proportion, or find others to supply their room. The Guardians, unfortunately, considered this plain and honest language as an infringement on their dignity. The Inspectors resigned; and other Medical Men were appointed in their stead. Now, mark the results: the new Inspectors, have shown themselves willing, not only to bind themselves to attend all who claim their aid at all hours, at a remuneration of six shillings a day, but have not scrupled to grasp at this degrading proffer, knowing that eight gentlemen of their own standing had just spurned it; aye, grasped it in the view of an indignant Profession, and scorning public,—how have they since acted? Has the Board of Guardians reason to congratulate themselves on their new acquisitions The answer is, that the new Inspectors have acted precisely as might be anticipated from the circumstances of their appointments. One of them has been, already, openly dismissed for falsifying returns; another's conduct is at present under investigation on the charge of demanding small fees from the poor. Do these occurrences militate against the character of our Profession? Not in the least. There are as honourable and high-principled men in the Medical Profession as in any other pursuit; but it is not by contumely or parsimony their assistance or confidence is to be obtained. If Boards of Guardians desire high-minded and trustworthy physicians for the service of the poor, they must in the Medical Profession, as in any other calling, come into the market with a free and open hand.

We have traced the declining steps of Medicine, as a Profession, in Ireland. We have done so with the purpose of endeavouring to rouse the Profession throughout Great Britain, and also the general public, to the dangers before them. We have demonstrated, that the authorities have long guided Boards of Guardians in the mistaken path of endeavouring to obtain the cheapest medical assistance for the poor; and that the manifest as well as rational results of this endeavour have been the debasement of professional honour and the cultivation of a mercenary spirit. We have seen the evils that must flow from regarding all the sick poor in the light of paupers; pauperization on the one hand, and demoralization on the other. The interests of the industrious poor, the welfare of the Medical Profession, and the safety and comfort of society at large, are bound together in this argument. It is for the advantage of all, that medical charities should be separated from poor-houses, and that their professional advisers should be treated with liberality and respect.

Accident from Chloroform.—An accident of a very melancholy nature has just occurred in Glasgow. Dr. Adams, Resident Physician to the Clyde-street Hospital, having occasion to use chloroform, inhaled it himself to try its strength, but without any serious consequence; repeating, however, this experiment, and incautiously increasing the dose, the effect was fatal:—he fell back and immediately expired.

THE OPERATIVE SURGERY OF JOHANN FRIEDRICH DIEFFENBACH.

Edited by
J. STEVENSON BUSHNAN, M.D.,
Fellow of the College of Physicians of Edinburgh;
And
ALEXANDER URE, Esq.,
Fellow of the College of Surgeons of England, and Surgeon to the Westminster General Dispensary, &c.

CHAPTER VI.
ARTERIOTOMY.

Arteriotomy signifies the opening of an artery with a lancet for the purpose of letting blood. The operation is usually performed upon the temporal artery; partly because arteriotomy is most frequently resorted to in inflammatory affections of the head, and partly because the bleeding can be readily stanched by pressure against the bone. There are three different modes of operating; in the first, the artery and superimposed integument are completely cut across with the lancet; in the second, the artery being fixed as the vein in bloodletting, is punctured longitudinally; in the third, the artery is exposed by an incision through the skin, dissected from the adjunct parts, encircled with a thread, and then opened longwise.

1. The first method is the least complex. The hair having been previously shaven, the patient is seated with the head leaning to the opposite side, against the breast of an assistant. The incision is made half an inch across, and both the skin and artery divided slantwise, the left thumb and fore finger being placed firmly to secure adequate tension, or else a fold of skin is taken up in the track of the artery, cut through transversely, and the artery severed by itself. The bleeding is copious only when the main trunk of the temporal is divided, because the branches contract forcibly. If the artery can be reached, a ligature may be applied, or the incision united with a couple of insect needles, subsequently wound with cotton thread and then cut short. Thus any risk of after-bleeding is prevented, and which might occur were merely a compress and bandage employed.

2. The longitudinal opening of the artery with a lancet, as in venesection, is a plan very uncertain, nd not to be advocated.

3. The exposure of the anterior temporal artery, as it ascends between the meatus auditorius and the articulation of the maxilla, after emerging from the parotid gland, is accomplished by means of an incision half an inch long. The adherent cellular texture is to be laid hold of with forceps, and carefully dissected from the artery. A thin, waxed silken thread is now conducted round the artery by the aid of a fine curved needle at the lower angle of the wound, and a second at the upper angle of the wound, and the vessel opened in the intervening space with a bistoury or lancet in the direction of from below upwards, or somewhat slantwise. The requisite amount of blood having been received in a shallow vessel, the ligatures are to be drawn and tied with knots, beginning with the lowermost; whereupon one end of the thread is to be snipped off, and the wound closed with adhesive strips.

After bleeding can take place only when the artery has not been secured with ligature, and this may be resorted to as a supplementary means. An insect-needle with twisted suture is, however, often more efficient than the supplemental ligature, hich is attended with difficulty when the artery has been divided; it is, on the other hand, of easy execution when the latter has been opened with a simple incision, and is capable of being encircled with a needle and thread.

The part is generally healed in the course of a few days; but, should suppuration follow, weeks may elapse before there is perfect adhesion. The loosened ligature is to be withdrawn with the forceps.

After the wound is united a false aneurism may form; that is, an effusion of blood from the still open artery into the cellular texture. This appears either as an elevated or as a diffuse pulsating tumour. It mostly occurs when no ligature, but merely a compressive bandage has been applied. If not curable by pressure, recourse must be had to opening the sac and ligation of the artery. Erysipelatous inflammation is an occasional, purulent deposit—a more rare sequel of the operation.

CHAPTER VII.
INFUSION.

Chirurgia infusoria.—Ars infusoria.—Ars clysmatica nova.—Paracentesis venarum.

By the term *infusion* is meant, the injection of a fluid into the veins; by *transfusion*, the transference of blood from the vascular system of one individual to that of another.

Infusion is seldom had recourse to in modern practice, except in cases of urgent risk of suffocation from the presence of a foreign body in the gullet, which can neither be withdrawn or pushed downwards; or where the propulsion would be dangerous, and œsophagotomy not immediately practicable. It may be further conditionally advised in several nervous diseases, hydrophobia, epilepsy, tetanus, and so forth.

It seems to have been originally tried on the human subject in England by Wren, in the year 1656, but Koehler was the first to establish its utility in relieving a man of a portion of flesh lodged in his throat, by the infusion of tartar emetic into his veins. Hemman cured epilepsy with musk, and a putrid fever by infusing a decoction of cinchona. Blumenbach instituted researches with air, and G. C. Siebold with opium. Meckel, the younger, cured a case of melancholy and apparent death with tartar emetic. Laurent, Percy, and Onsenoort were successful in tetanus with opium and extract of stramonium. Magendie injected water and other matters; Von Graefe tartar emetic; saline solutions were thus exhibited by Froriep in cholera. I have myself pursued the practice of infusion in numerous instances with various results; in none was the issue fatal.

As regards the general action of substances introduced into the circulation in this way, it may be assumed, that even the most harmless, as tepid water, may prove mortal if urged too quickly, or mixed with air. Other fluids of a thick consistence cause death by obstruction of the capillaries of the lung, such as oil, mucilage, and also quicksilver.

It is obvious that the operation of infusion must be viewed as an extreme expedient, only to be used ith reserve and precaution, and where other remedial means have failed. The cases in which it may be justifiable are those of suspension of respiration from hanging, strangling, intoxication, trismus, hydrophobia, epilepsy, choking from mechanical obstruction causing closure of the glottis, but, above all, hæmorrhage.

Of the liquids employed for this purpose, epid water is the principal. Magendie witnessed he most alarming hydrophobic symptoms assuaged by its employment. When injected at low temperature, it determines a kind of gue fit, and very readily inflammation of the ungs. Salts, such as nitre, sulphate of soda, chloride of sodium, produce respectively their cooling, aperient, diaphoretic, and diuretic effect. It is, however, seldom necessary to employ them thus, except in the instance of cholera, because they generally act with certainty when taken into the stomach. A solution of tartar emetic operates in a few seconds, and is not followed by any bad consequences; sometimes, indeed, emesis is postponed, or alvine evacuation ensues without vomiting. With the "Aqua Binelli," a hæmostatic nostrum, the results were negative.

The operation is performed on a vein at the bend of the arm; an opening being made with a lancet, the warm liquid is thrown in with a syringe. The patient is to be seated as for blood-letting. A bandage having been applied round the arm, a fold of skin is taken up and divided with a scalpel to the extent of three-quarters of an inch. The vein is now perceptible as a thick bluish cord within the wound. The superincumbent cellular texture is to be raised up with dissecting forceps, and separated

with a few scratches of the knife. At both the upper and the under angles of the incision, a thick waxed silken thread is to be insinuated beneath the vein, and placed, without being tied, in the hands of two assistants, by whom each is to be slightly drawn, in order to confine the blood in the interspace.

The next step is opening the vein, which is effected with a small scalpel; on dilating the puncture thus made, a portion of the pent-up blood escapes. Taking advantage of this moment, when the wound in the vein is most conspicuous, the surgeon introduces a small slightly curved tube, an inch and a half long, furnished superiorly with two rings for securing it, into the vein half an inch deep, of course directed towards the heart.

Then follows the injection. A trustworthy assistant charges the pump or syringe with the warm liquid, turns it with the nozzle upwards, and presses on the piston so as to expel any entangled globules of air; he then approaches it to the canula in the vein, which he fills brimful with the liquid, without, however, connecting the nozzle and canula together. When the canula is full, he then inserts the syringe nozzle within it, and while one assistant slackens the uppermost thread still in his hands, the operator slowly propels the contents of the syringe. This must be executed very gradually, and an occasional pause made, so that the transit of two ounces of liquid should occupy at least five minutes. The canula lies unattached within the skin, of which the walls are grasped by the left thumb and fore-finger of the operator, lest it fall out, or the fluid flow back.

After the procedure is terminated, the canula is to be withdrawn, still full of liquid, the vein meanwhile being fixed, the wound cleansed with a wet sponge, the threads removed, and the cut edges retained in apposition with spirally laid strips of adhesive plaister, surmounted by a compress and roller. The arm is to be kept at rest for fear of suppuration. The dressing is not to be disturbed until the wound is healed.

If the operation have to be repeated on the first or second day, the wound must be carefully opened afresh, by delicately drawing the lips apart, after previous fomentation with hot water; and then proceeding as above described. If, however, three or more days have elapsed, a vein must be opened in the other arm, for repetition of the infusion. The selection of a second vein in the same arm is improper, both on local and general grounds. The close proximity of the two wounds is apt to produce diffuse cellular inflammation and phlebitis. No foreign substance ought, for any consideration, to be introduced subsequently within the vein, as it will only tend to irritate and do mischief.

I have found the above mode of operating the most efficient and least perilous. It possesses the following advantages: it renders impossible all ingress of air; the canula is easily introduced; and any annoying hæmorrhage from the orifice prevented by the traction of the thread. If an attempt be made to substitute mere pressure with the finger for that of the ligature, at every instant the wound will be welled with blood, and it will be next to impossible to find the opening with the canula; if, again, the blood be washed away, the vein will become so collapsed, as to be scarcely cognisable. Ligation of a vein is fraught with even more jeopardy after the operation of injection than at other times; and is, moreover, quite as superfluous as after bloodletting.

REVIEWS.

On the Cryptogamous Origin of Malarious and Epidemic Fevers. By J. K. Mitchell, A.M., M.D., Professor of Practical Medicine in the Jefferson Medical College of Philadelphia. Pp. 137. Philadelphia: Lea and Blanchard. 1849.

By demonstration, the truth of a proposition is made unequivocal. Induction may lead to a degree of probability little short of certainty. The highest amount of proof the argument from analogy affords is, that of rendering a statement not very improbable. By induction we pass from known facts to general laws respecting those same facts. In the argumen from analogy we reason not from facts identical in kind, but only from facts bearing some similarity to each other. Analogy is the foundation of most theories; induction of laws. The laws that regulate the spread of epidemic diseases are capable of being ascertained by long-continued and accurate observation, and by careful induction from the facts observed. Science may, when these are discovered, stay the desolating effects of epidemics, by removing the conditions necessary for the development and diffusion of the poisons on which they depend. The nature of matter can only be known by demonstration; that which admits of demonstration ought not to be inferred from analogy.

To illustrate our assertion, that analogy affords no proof, a fact too often forgotten by the framers of theories, the book before us offers a curious example. Having observed, that fungi leave behind in the soil from which they spring, a something incompatible with the growth of the same species of fungi in the same soil, our Author remarks, that we can readily understand, reasoning from analogy, why small-pox should only attack a person once during his life; for, says he, if the first attack be due to the development of fungi in the blood, then will these leave behind them a something incompatible with the growth of the same species a second time If this mode of reasoning be correct, a something is superadded to the normal blood during the progress of small-pox.

Another hypothesis to explain the fact of the non-recurrence of small-pox in the same individual has been advanced and supported by Professor Liebig. It is the theory of ferments. Suppose, says that illustrious chemist, that in the blood of the infant there exists a kind of matter capable of undergoing a species of fermentation, which process is the disease called small-pox, that this matter, like all fermentable material, is capable of being excited into action by a small portion of the same matter in a state of fermentation, then a person affected with small-pox gives off a portion of this ferment, and so excites small pox in one who has not had that disease; but when once the disease has terminated, then the fermentable matter being all destroyed, the same action cannot be renewed. So that according to this second hypothesis, as strongly supported as the former by analogy, a something is removed from the blood while the patient experiences small-pox. As if to expose the weakness of this mode of reasoning, a third hypothesis has been started by Mr. Paget, who, rejecting the matter added according to Professor Mitchell, and the matter taken away according to Professor Liebig, considers that some change takes place in the blood itself during the progress of small-pox; and refers the insusceptibility of a person to a second attack, to the assimilating power of the blood, whereby it makes the new blood to resemble itself in all particulars.

Having thus given our readers to understand that analogy is held by us as of little value when brought forward as proof of the truth of theory, and believing that the attempts to determine the *nature* of epidemic diseases in our present state of general knowledge is futile, that time is wasted in the endeavour, which had far better be spent in efforts to learn the laws which regulate their development and diffusion, we may state that it being understood that the foundation of Professor Mitchell's theory is analogy, it is one of the best worked out we ever read. Every page of the work speaks of the extensively read scholar and ingenious reasoner. The book consists of six lectures delivered by the Author to his class in the Jefferson Medical College, Philadelphia, in which he holds the rank of Professor of Medicine.

In the first Lecture the Author demolishes, very effectually, the malarious and other partially received hypotheses, and then proceeds, in the subsequent Lectures, to build up his own theory, which is, that all epidemic diseases, and cholera and yellow fever in particular, have, for their immediate cause, the presence of fungi in the atmosphere and in the blood, the spores being absorbed through the pulmonary mucous membrane.

Professor Mitchell's chief arguments in favour of his own hypothesis, are founded on—

The vast number, extraordinary variety, minuteness, diffusion, and climatic peculiarities of the fungi.

The power of the spores of fungi to penetrate into and germinate upon the most interior tissues of the human body.

The alleged fact, that, introduced into the body through the stomach, or by the skin or lungs, cryptogamous poisons produce diseases of a febrile character, intermittent, remittent, and continued; and it is here also stated, that "many cutaneous diseases, such as favus and mentagra, are proved to depend upon cryptogamous vegetation, and even the disease of the mucous membrane termed Aphthæ, arises from the presence of minute fungi." This latter is undoubtedly an error, for the minute vegetations in the scabs of favus, &c., exist there only because the spores find in the diseased secretions a nidus suited for their development.

The frequency with which epidemics are accompanied by a fungiferous condition of the earth and atmosphere, even when the hygrometric state of the latter does not afford any unusual moisture for their sustentation and propagation.

The great prevalence of endemic and epidemic diseases in autumn, and the fatality of exposure to night air in marsh countries, may, according to the hypothesis, be explained by the greater powers of growth of fungi at those times; and the habits, it is asserted, of the known species of cryptogamic plants, explains certain facts respecting epidemic and endemic diseases inexplicable on any other hypothesis, such as their localization, the obstruction offered to their spread by a road or wall, a screen of trees, &c, the security afforded by artificially drying the air; the phenomena of the curious disease of cattle called milzbrand, and the milk sickness, and the wonderful irregularities of the progress of cholera. How far it explains the non-recurrence of small-pox, &c., to which explanation its Author attributes some value, we have already seen.

To those who are fond of ingenious theories, we strongly recommend the little book before us. While men who, like ourselves, look in general on such productions but as the glitter and tinsel of medicine, which, however enticing, ought never to lead us from seeking the sterling gold of fact, will yet be amused, and even edified by these pages of what their accomplished Author himself aptly styles, "mingled reason and fancy."

MR. CHARLES KNIGHT'S MANUALS.

Manuals of the Duties of the Poor-law Officers.—Medical Officer. By W. G. Lumley, Esq., Barrister-at-Law, one of the Assistant Secretaries of the Poor-law Board. 12mo., Pp. 92. C. Knight, Fleet-street.

The Nuisances Removal and Diseases Prevention Act, 1848 (11 and 12 Vict., c. cxxiii); with an Introduction, Notes, Index, and Appendix, &c. Second Edition. By W. G. Lumley, Esq., &c. 12mo. Pp. 168. C. Knight.

The members of the Medical Profession, interested in the administration of relief to the poor, have to thank Mr. Charles Knight for a very useful and unpretending little Treatise on the Duties of the Poor-law Medical Officers. It supplies a very lucid exposition of the various matters with which it is desirable the Medical Officer should be fully acquainted. It gives accurate details concerning the appointment of Medical Officers to the workhouse and to districts, the requisite qualification, the remuneration, the term of office, and the regulations as to the personal discharge of duties. The book also contains a distinct enumeration of the duties prescribed by the regulations of the Commissioners, and those which the Legislature have deemed it expedient to impose. We have no hesitation in stating, that this Manual ought to be in the hands of every parish surgeon throughout the length and breadth of the land.

Mr. Charles Knight is also entitled to the best thanks of the community for another little volume,

detailing the Act for the Removal of Nuisances and the Prevention of Diseases, and containing ample particulars of the measures which have emanated from the Imperial Parliament, and from those in authority under it, relative to these important subjects. Assuredly, at this time, when such well-grounded alarm is felt on all sides for "the pestilence that walketh in darkness, and for the destruction that wasteth at noon-day;" when thousands are falling weekly, it behoves each individual in the realm to be acquainted with the means which have been enjoined for abating this fearful mortality. Every householder or head of a family ought to be in possession of this excellent digest.

DISINFECTING LINEN.

[To the Editor of the Medical Times.]

SIR,—The mysterious agency by which complaints of the most serious nature are conveyed from one individual to another, and the sudden attacks and dangerous diseases to which apparently healthy persons are subject, have long been matter of scientific and medical investigation, but yet remain impenetrable to human sagacity. That all effects proceed from causes is too self-evident a proposition to be disputed; and in the absence of positive evidence every one theorises on some favourite notion of his own; some ascribing the prevailing scourge of the cholera to a superabundance of electric matter in the atmosphere; some to a deficiency in this fluid there or in the earth itself; another to excess in living; another to want of proper diets and stimulants. Whatever else be the cause, it is clear that where there exist unwholesome exhalations, unventilated and unclean dwellings, or dirtiness of person, a predisposition to cholera exists, and it finds more abundant victims in such quarters. What holds good in the case of cholera is applicable to disorders of a less dangerous and fatal kind.

The question of contagion or non-contagion, in a vast variety of maladies may be left to the disquisitions of the curious in these matters. As to cholera, the prevailing opinion is, that it is contagious; but taking natural feelings for our guide, whether as exhibited in the reason accorded to humanity, or in the instinct vouchsafed to animals, by the Great Parent of the Universe, there is a natural repugnance in a healthy and sound person to approach near to, or touch, the person, or clothing, or bedding, of a diseased and suffering individual, the office of ministering to the wants of such being mostly left to some near female relative, or to nurses hired for the purpose. But some diseases are notoriously contagious, and require the most particular avoidance, not only of personal contact, but of the clothes, and bedding, and atmosphere breathed by affected persons. There are, at least, twenty-one diseases recognized by the faculty as contagious, and it is well known that human effluvia are at all times injurious to health, and, in a closely concentrated state, is fatal to life. This morbid effluvium is given off powerfully by persons in a sick state; vitiated perspirable matter is absorbed by the body and bed linen of the patient, and there is no substance which retains the poison in some diseases, and the miasma in all, than the *linen* and *cotton* of which the inner clothing and bedding are universally composed. This brings us to the subject matter of these remarks, of which the foregoing is the exordium.

The various modes in which attempts have been made to take the grease out of woollens, to clean and whiten cottons, and wash linen in domestic use, show that the problem to be solved simply consists in saponifying the animal and vegetable greases contained in them. The manufacturers of cloths and of calicoes, who make use of soap water and soda to saponify the greases therein contained, know perfectly well, that the degree of the heat of the water, and the degree of strength of the sod, must be calculated to a great nicety, otherwise these greases become fixed both in wool and cotton, instead of being extracted therefrom. Still, however, we go on washing the clothes of our houses and our hospitals, &c., with the same materials, soap, soda, and water, but permitting the servants to employ these substances by mere chance, the result of which is, that the clothes acquire a grey or yellow hue. It, therefore, follows, that the grease in the linen of domestic use is very analogous to that contained in wool, and requires the same process for its extraction; but it is certain that a portion of the grease which the linen contained, previous to its washing, still remains in it, if it does not undergo the same process as that needed for extracting it from wool.

Let us now suppose linen used by a patient labouring under fever, or any other disorder which is accompanied by violent perspiration: might it not be reasonably apprehended that the disorder might be communicated by another person using such linen in which the perspiratory matter yet remained, from imperfect washing? This is of frequent occurrence in the hospitals, where the linen of a patient afflicted with (or who had even died died of) cholera, is handed to a cured patient on the eve of returning to his family.

In public bath-houses, a peculiar process of *quickly drying*, enables the bathers to use the same towel to the extent of twenty different persons in a few hours. It is clear, that here mischief may and does arise, which imperatively calls for prevention at the hands of all scientific men and philanthropists.

The modern usage in London, and in other large communities, has changed the domestic habits of our ancestors, and instead of the family clothing forming the occupation of a periodical washing *at home*, it is now too common for families to entrust their clothes to the laundress, and never to consider or inquire with whose clothing the ablutions have been jointly made. The fact, however, is, that, without respect to rank or condition, -without regard to health or sickness,—without, indeed, a moment's consideration of the consequences,—the heterogeneous mass is confided to one *common tub*. The manifestations of rubbing till the skin of the washerwomen's hands comes off, and the strength of the clothing destroyed, go on through three waters, and end in a partial cleansing, without effecting any complete purification. Much greasy matter remains, and that in a state highly capable of conveying contagion.

Discussing this subject with a foreign gentleman, some time since, he acquainted me, that in parts of the Continent, and more particularly in the South of Europe, use is made in hospitals and other public institutions, and enforced by laws of an ancient process, called "*The Lessive*," the good effects of which have been acknowledged for ages; that its operation required time, care, and rather laborious work; but that he himself had invented and patented an apparatus simplifying this ancient mode of "the lessive," by which the labour is more than half diminished, the operation much shortened, and the expense greatly economised, whilst the purifying process was complete. Seeing that I manifested a desire to see the apparatus at work, he kindly and courteously invited me so to do, fixed a time for the purpose, and engaged me to send a quantity of soiled clothes from my own family and friends, that I might see the effect upon them, desiring that they might contain some articles well stained and discoloured by age and use. Accordingly, at the appointed time I witnessed the whole operation, from the beginning to the placing the articles to dry. The apparatus consists of an ordinary fire-grate, communicating by a short funnel to the kitchen chimney. Over this is a boiler with a false bottom, containing water to a small extent, and regulated by a cock in its side. Into this cistern, provided with free passages for the steam, the clothes to be washed, being previously submerged in cold water, containing a little common soda, are placed without any rubbing or scrubbing whatever. Steam and water of various temperatures are conveyed constantly to them, and through them by the aid of a small pump, which discharges the water over the clothes till all the foulness is purged and carried off. This variety of temperature is necessarily applied, seeing that the soils of linen vary, and that whilst a certain degree of heat will dissipate some stains, others will be unaffected. The cistern is so contrived, that no fire can approach to burn the linen,—a small quantity of wood served the fire for about two hours, and the economy of soap, as compared with that article in ordinary washing, was said to be a saving of three pounds out of four.

By this simple and easy process—to be taught in one lesson, and worked by a child—the linen is made quite clean, is of extraordinary whiteness, is entirely free from smell, and being subjected to cold immersion, was in a few minutes conveyed to the drying yard. The apparatus itself distinctly showed when the steaming operation was finished. The economy is great; but the comfortable reflection is, that there is no improper mixture of clothing, no risk of contagion, and wherever sickness had prevailed, or death had happened in a family, the patient's clothes and bedding could be subject to a distinct cleansing. Linen and cotton body clothes which have undergone the usual process of washing, if submitted to "the lessive," will still yield a sufficient quantity of fat or grease to form soap, thereby, I think, showing that ordinary washing does not prevent contagion. I am aware that this may not be altogether a medical subject; but referring, as it most assuredly does, to a matter now painfully affecting the public health, I trust it will find a place in your *Medical Times*, and I shall be happy to give any further information in my power to those who shall desire it.

I am, Sir, most obediently yours,

G. W. BLANCH, M.R.C.S., Edin.

3, Albion-place, Blackfriars-road, Sept. 1, 1849.

DR. STEVENS' SALINE TREATMENT.

[To the Editor of the Medical Times.]

SIR,—In perusing the article on Dr. Stevens' Saline treatment of Cholera, contained in the last Number of your valuable Journal, I find that Dr. Stevens recommends soda effervescing draughts when the stomach is very irritable. Now, I have tried these draughts largely with the double object of administering the saline treatment, and, at the same time, allaying the vomiting; but they appeared to me to have quite an opposite effect; and so thought my patient, who was dreadfully afraid of the "fizzing draughts," as he termed them, and at length refused to drink them, on the plea of their increasing his sickness.

In this case, the rice-water evacuations having continued almost incessantly for four days, I at last tried the following draught, which was perfectly successful in checking the vomiting. Nor did the irritability of the stomach re-appear:—

℞ Acid. hydrocyan. dil., ♏iij.; sodæ bicarbon., gr. vi.; aquæ puræ, ℥j. M.

I remain, Sir, your obedient servant,

J. D. C.

Portsmouth Sept. 2, 1849.

CHOLERA IN DUMFRIES.

[To the Editor of the Medical Times.]

SIR,—In answer to your Dumfries' Correspondence, published September 1st, allow me, through the medium of your columns, to offer an apology, and with it an excuse for my error. During the virulence of cholera in Dumfries, in a conversation with Dr. Grieve as to the probable causes, or those ascribed for the epidemic, I spoke of the shock which I invariably experienced from contact with a choleric patient, as a fact to support the theory, ., that there was a close intimacy existing between that disease and electricity; at the same time expressing my surprise that no writer had called attention to the subject. Dr. Grieve did not then correct my error; but, in doing so now, adduces my youth as an aggravation of the offence—presuming upon which (I suppose) the letters of Drs. Grieve and Browne have been followed up by some editorial remarks perfectly uncalled for.

My letter, of August 26th, had special reference to the propagation of cholera by contagion; and had this subject—merely introduced as a casual observation—been corrected with more *feeling*, the remarks would have been better appreciated. With a deep sense of—and sorrow—for my ignorance in professional literature,

I am, sir, your most obedient servant,

JAMES SMYTH.

Coleraine, September 3, 1849.

NITROUS OXIDE IN CHOLERA.

[To the Editor of the Medical Times.]

SIR,—Having witnessed the effects of *nitrous oxide*, when inhaled experimentally, the notion occurred to me, that it might be useful in cholera. I commenced a search which extended through different Medical Journals, and among the recorded professional experience of 1831, and the following year, there is a suggestion (*London Medical Gazette*, Nov. 19th, 1831) for the use of the above vapour; in the writer's own words, he thinks that "the symptoms (of cholera) might be *relieved* by the inhalation of the *protoxide of nitrogen*, or *dephlogisticated nitrous air* of Priestly." In another paper, by Dr. Shearman, (*Lancet*, 14th Oct., 1848,) the contributor says:—"I have made up my mind, should nothing more be discovered respecting the pathology of cholera; and, considering

the failure of every other mode of treatment, that I will treat any case verging into the state of collapse by first taking away as much blood as I reasonably can from a vein in the arm, (no easy matter,) and then immediately transfuse warm blood from the most healthy subject I can meet with, *and keep up respiration as long as possible, with equal parts of oxygen gas and atmospheric air.*"

Can you, or any of your readers inform me, if nitrous oxide, or an atmosphere charged with oxygen, has ever been exhibited by way of the lungs, as an antidote for cholera,—under what circumstances,—and with what result?

Being a student, I ought, perhaps, to hold myself contented with merely asking the question,—leaving it for more experienced men to reply. But, I cannot refrain from saying, that, in looking over the numberless papers having reference to the pathology of cholera, I am strongly impressed with the idea, that nitrous oxide is indicated as an important remedy. To select one instance from many others:—Dr. Bell, (*Med. Gazette, Jan. 7th and 14th*, 1848,) after maintaining cholera to be 'a form of ague, of the quotidian type, and after showing the congested state of the veins and capillaries, speaks thus of *iron* as a curative agent." Iron seems especially used for the purpose of *facilitating the oxygenation of the blood*, and enriching it as in chlorosis, and in aiding the action of a feeble heart, probably by its influence in causing the blood to pass more freely through the lungs, and thus diminishing the tendency to congestion," &c. If iron, therefore, be of so great utility, may it not be presumed, that nitrous oxide will prove of still greater use in the oxygenation of the blood, in the relief of congestion, and in its generally stimulating effects upon the system; being, moreover, by inhalation, applied directly to the seat of the evil? But there is another author, whose opinions I will presume to cite, inasmuch as they fully corroborate my own previously-adopted views of the origin of the disease, and as he shows by arguments, *à priori* as well as *à posteriori*, the want of an agent like that I have suggested. Mr. Thom says, (*Med. Times*, March 11th, 1848,) that "with an increase of *temperature* and *moisture* there is also an augmentation of the bulk, and diminution of the specific gravity of the air; so that a volume which fills the lungs contains a *proportionately less quantity of oxygen* than it would otherwise do. . . . Yet we admit that this alone is not sufficient to produce those death-blasts which pass over India in certain seasons, but that it is merely the first link in the chain of causation. . . . Let us suppose any sudden or unusual congestion to take place in a system already impregnated with so much grave, although latent, germs of disease. . . . It is almost needless to observe, that such a phenomenon would lead to the most dangerous and fatal results. . . . The next point which forces itself upon our notice is, *the presence and agency* of phenomena during and preceding cholera, which *were eminently favourable to a morbid congestion of the circulating mass*, whether previously deteriorated or not; these I consider to be, undue moistures in the air, and a deficiency of the ordinary currents of winds; both being equally unfavourable to the process of evaporation."

It needs no very profound knowledge of meteorology to discover an analogy between these characteristics of an Indian climate and those of our present summer; but, abandoning this point, may it not be reasonably surmised that the poisonous effluvia of the churchyards and sewers of large cities, like London, contaminate the air and produce cholera, not merely by admixture, but by a chemical union with its important element—oxygen? Certainly, the air, like any other gaseous mixture, is subject to such chemical deterioration; and, perhaps, the wide diffusion of the disease is thus more readily accounted for.

I regret having troubled you with so long a letter; but in order that my question might not appear trivial, I have been obliged to explain, in some measure, my reasons for asking it. I am in daily anticipation of having some cases of cholera to deal with, and I should really feel extremely obliged for your opinion as to the propriety of using nitrous oxide in a dilute state, if collapse should ensue.

Yours respectfully, F.

CHOLERA TREATED BY SALINE INJECTION.

[To the Editor of the Medical Times.]

SIR,—The intense interest which all must feel in that fearful malady, the cholera, will, I trust, be a sufficient apology for my requesting the insertion of the following remarks in your valuable Journal.

I was sent for on Tuesday, the 21st instant, at 12 p.m., to visit Benjamin Jolly, aged 15 years, of spare habit, and residing at 13, Stanley-street, Great Western Railway. I found him suffering from true Asiatic cholera. The symptoms had run a rapid course: he was quite pulseless, the purging, vomiting, and cramps had been of a most severe character; the rice-coloured evacuations extremely profuse, thirst intense, the corrugated and blue skin strongly marked, and when I arrived he was in a state of collapse. Having the Sunday previous witnessed the marvellous effects produced by saline injection into the veins, I determined, without a moment's hesitation, to employ this remedy, feeling sure that no means ordinarily adopted, (and I witnessed every mode of treatment in four or five hundred cases at Yarmouth in 1832,) would prove of the least avail. Not being aware, till I arrived, that it was a case of cholera, some valuable time was lost in procuring assistance and the necessary apparatus. I called up my friend, Mr. Girdwood, who immediately accompanied me, and, on reaching the patient, found the icy coldness of the body more decided, and the collapse more complete, and, in my opinion, he was decidedly moribund. We immediately opened a vein in the arm, and injected a quart of water at 98° Fahr.: in which 1 dr. of common salt, and ½ dr. of sulphate of potash were dissolved. In less than ten minutes our patient showed symptoms of resuscitation; the pulse returned, the skin became warm, the blue and corrugated skin resumed its natural appearance, and as soon as the warmth became more general, and the pulse was fully re-established, we enveloped him in a sheet wrung out in cold water, and covered it with several layers of blankets; hot bottles were applied to the pit of the stomach, and the calves of the legs and feet; a profuse perspiration was the speedy result. Allowing this to continue for upwards of an hour, we removed the sheet, and placed our patient in bed, enveloped in hot blankets; his pulse was then 120, quite firm; his skin warm and moist; his reason completely restored, and on his expressing a wish to sleep we left him. On my visit in the morning, I was delighted to find him much better. Some sickness and fever existed; but were speedily arrested by small doses of calomel and opium. Each day since he has gone on improving, and is now convalescent.

This case but confirms me in the opinion I have long entertained, that saline injection into the veins, if adopted before the patient becomes in too collapsed a state, is the most rational treatment, and one which I feel assured, if a fair trial were given it, would be crowned with abundant success. It narrows itself, in my opinion, into a very small compass, demand, and supply. The blood is generally deprived with intense rapidity of its serum, so as to leave it in such an inspissated state, as to be in a case I saw lately, thicker than treacle. What, then, so rational, as to supply it with its fluid properties again, and that immediately? Not by the slow process of absorption, which must, of course, be the more tardy the greater the collapse, but by introducing it at once into the circulation. I would urge my medical brethren to try the usual mode of treatment, particularly that of Dr. Ayre, in the first stages of the disease; should they fail, however, in arresting its progress, and collapse set in, not to lose a moment in employing venous injection; and the result, I am fully persuaded, will be the rapid diminution of deaths from that so fearful scourge—the cholera.

I am, sir, your obedient servant,

HENRY HOWLETT.

18, Cambridge-terrace, Hyde-park,
Aug. 30, 1849.

ASTRINGENT INJECTIONS INTO SUPPURATING CAVITIES.—Dr. Brainard, of Chicago, has made some practical remarks in reference to the treatment of extensive suppuration by astringent and stimulant injections into the suppurating cavity. In these cases, free openings, and washing the surface within with a solution of ℥ij of alum, and ℥i of sulphate of copper to the pint of water, will check its progress, diminish the quantity, and improve the quality of the pus. He is inclined also to think, that the practice prevents purulent absorption, and, by exciting inflammation, limits the spread of pus among the tissues. The same application he has found useful on the surface of large stumps, where the pus is abundant and offensive.

BANGOR AUXILIARY BRANCH OF THE PROVINCIAL MEDICAL AND SURGICAL ASSOCIATION OF ENGLAND.

A meeting of medical men was held at the Liverpool Arms Hotel, Bangor, on Wednesday, Aug. 29, for the purpose of forming an Association of the Profession in North Wales, in connexion with the Provincial Medical and Surgical Association.

There were present, John Roberts, Esq., M.D., of Bangor; Thomas Taylor Griffith, F.R.C.S., Wrexham; John Lloyd, of Llangefni, Esq.; John W. Pring, of Bangor, Esq.; D. Kent Jones, Esq., of Llangefni; D. Williams, Esq., Surgeon to the Anglesey district of Bangor and Beaumaris Union; D. Hughes, Esq., Surgeon to the Carnarvonshire district of Bangor and Beaumaris Union; Thomas Charles, Esq., Bangor.

Letters approbationary of and promising support to the meeting having been received from many other medical practitioners, were laid on the table.

Mr. Taylor Griffith, Wrexham, was by acclamation elected President of the "North Wales Branch" of the Provincial Medical and Surgical Association of England.

The following gentlemen were nominated as a Council, viz.:—John Roberts, M.D.; John Lloyd and J. W. Pring, Surgeons.

Secretaries:—D. Kent Jones, D. Hughes, and D. Williams, Surgeons.

The President having taken the Chair,

Dr. John Roberts rose, to move a resolution. With regard to Union officers, it was felt that their situations are not certain, that they are not properly remunerated; but the great grievance seemed to be that they are placed under the control of Boards of Guardians. To obtaining a remedy for those grievances their efforts should be directed. The College of Physicians and the Apothecaries Company had promised to assist; but the Royal College of Surgeons have all but refused to petition. He thought best to petition on their own account; a strong application from all the Unions in the kingdom, concisely and graphically putting their case, would be attended to, he thought.

Mr. Kent Jones seconded the resolution. Union officers, he said, had many grievances to complain of; but he hoped that better times were coming; trusting that Government would see the necessity for making some change in their position, he agreed with Dr. Roberts, that petitions from each Union would be attended with good results, as having greater weight.

The case of the Union Medical Officers had been received very kindly by some of the Medical Boards; not so, however, by the College of Surgeons. It would, therefore, be for the Union Surgeons, assisted by other medical gentlemen, to press their case on the consideration of the Government in such a way as to be effectual.

The President, in putting the resolution, suggested a Committee to prepare a petition, to be signed by the Chairman on behalf of the meeting; then to have as many separate petitions as possible independently.

Mr. J. W. Pring, moving a resolution, spoke in favour of organized combination, as the best means for obtaining their object.

Mr. D. Hughes, of Bangor, seconded the resolution, expressing his concurrence with the proceedings, which he regarded as an important step towards establishing the independence of the Medical Profession.

Mr. J. Lloyd enforced the necessity for looking after the interest of the Medical Profession.

After some further conversation, leading to the

appointment of the officers, Mr. Pring moved the marked thanks of the meeting to Dr. Griffith, for his kindness in coming so far to meet his juniors, he having one of the largest practices in Wales to attend to.

Dr. John Roberts seconded the resolution.

The President returned cordial thanks. The Society would have his best wishes, and, he hoped, his best exertions. The step they had taken he considered very necessary to the Profession.

Mr. Griffith then retired, and there being some letters to read, Dr. John Roberts was moved to the chair.

Letters apologising and accounting for absence, were read from Dr. Lloyd Williams and Dr. Cumming, of Denbigh; Mr. Price Roberts, of Ruthin; Mr. Richards, Bala; Dr. O. Roberts, St. Asaph; Mr. Walthew, of Holyhead, and others, highly approving of the objects of the meeting, and communicating valuable suggestions. Some of the letters covered subscriptions.

The subject of a fund for the temporary relief of medical men, in case of sickness or poverty, of which Mr. Newnham, of Farnham, Kent, is the founder, and another fund for giving annuities to the widows and orphans of medical men, got up by Mr. Daniell, of Newport-Pagnell, were introduced and discussed. It was considered by the meeting that the amalgamation of the two would be highly beneficial.

Dr. John Roberts strongly advocated the Medical Annuity Fund.

Thanks were voted to Mr. Lloyd, with whom the proposition originated, for his exertions in the cause.

The meeting then broke up.

The major portion of the medical practitioners dined together at the Hotel when the proceedings had closed.

MEDICAL NEWS.

Apothecaries' Hall.—Names of gentlemen who passed their examination in the science and practice of medicine, and received Certificates to practise, on Thursday, August 30, 1849:—Henry Swift, Farnsfield, Nottinghamshire; Theodore Henry Stratten Royle, Stanfield, Norfolk.

Guy's Hospital.—Mr. Hilton has been elected Surgeon to this Hospital, vacant by the death of Mr. Aston Key.

Cholera.—This disease has rapidly increased during the past week in various parts of the country and in the Metropolis. The mortality has been frightfully great. The *New York Herald* gives an account of the disease appearing on board the ship Sheridan at sea. She lost thirty-one of her steerage passengers and seamen. The cholera broke out among the crew on the 7th of August. For the first eight days there were from eight to ten new cases, and from three to five deaths daily for eight days in succession. Out of twenty-two seamen, only four could be mustered in a watch. Eighty cases and thirty-one deaths occurred from the time the ship sailed. All that could be done was done by Captain Cornish and his officers for the sick. Several were ill when the vessel reached Staten Island; they were taken to the hospital.

The deaths registered in London in the week ending September 1 were 2796, of which 1663 were by cholera, 234 by diarrhœa. The mortality exceeds that of any previous week. The greatest number ever registered before in any week since 1840 was 2454 deaths, in the week ending December 4, 1847, when the last epidemic of influenza prevailed. In the cholera epidemic of 1832, parish clerks, in the old bills of mortality, returned 1021 burials for the week ending August 28: which, allowing for the defects in their returns, and for increase of population, are equivalent to 2450 deaths at the present time. The burials after that week in 1832 declined. The mortality is nearly three times the average of the season, and is sensibly felt all over the metropolis; but the inhabitants of the north and west districts, and people in the distance, can yet scarcely form a notion of the suffering on the south side the Thames, and since the middle of August, in the east districts. "The 12th, 13th, and 14th of August," says one of the registrars of Bethnal-green, "will long be remembered in this neighbourhood, the outbreak of this fatal disease being without any adequate preparation; surgeons were wanted in many places at once; the hurried passing and repassing of messengers, and the wailing of relatives, filled the streets with confusion and woe, and impressed on all a deep sense of an awful calamity."

Cholera has already destroyed, in this epidemic, 9129 lives in London.

As it is one of the purposes of the Registration Act to ascertain the "causes of death," and of the weekly tables not to gratify idle curiosity, but to point these out to the public, the registrars have been requested to give all the information they can respecting the state of every part of their districts. This many of them have taken considerable pains to do, and their notes will, it is hoped, be found serviceable to the Guardians and Medical Inspectors, now and at future times. For it is important to bear in mind, that cholera only brings into a strong light the localities which elaborate calculations in the Annual Reports prove are at all times fatal to the health and life of the inhabitants.

After the perils of this terrible week we seem to see land; but as many thousands of lives may be lost in an epidemic by negligence, so many thousands may be saved by skill, vigilance, and energy—by more ample supplies of water—by the rapid removal of nuisances from the houses and streets—by the prompt administration of medical appliances and other comforts, by the active co-operation of the Medical Profession, of the Boards of Guardians, of employers, of every householder, of every individual, with the Board of Health, and health officers."

The New Queen's Colleges.—The General Assembly of the Presbyterian Church in Ireland is to be convened "to consider whether the Queen's College at Belfast is now so constituted as to justify the attendance of their students."

Devon and Exeter Hospital.—A fancy fair was held last week at Exeter, the receipts of which for the benefit of the Devon and Exeter Hospital, amounted to 1,519*l.*; and donations have since been received raising the amount of the proceeds of 1,644*l.*

Oxford.—A site has been chosen, at Oxford for the erection of a new University Museum, which is expected to cost more than 50,000*l.*; of which part will be raised by subscription, and the remainder will be supplied from the University chest.

Six Professors of the University of Heidelberg have been suspended, for having taken part in the late insurrection in Baden, and thirty students have been expelled for the same reason.

Illegal Medical Practitioners.—A case was on Wednesday last tried at Hungerford before the County Court of Berkshire, in which a person named Bishop, who resides at Ramsbury, in Wiltshire, was charged by the Apothecaries' Company with practising as an apothecary without being legally qualified. Mr. W. H. Rowland, who appeared for the plaintiffs, stated the nature of the case, and explained that the action was brought under the 55th of George III. c. 194, commonly called the Apothecaries' Act, by which it is provided that it shall not be lawful for any person or persons (except persons then in practice as such) to practise as an apothecary in any part of England or Wales, unless he has passed his examination and received a certificate of his being duly qualified. He then adduced evidence to prove that Bishop, who possessed no certificate, had acted as an apothecary, and furnished medicines for the use of a man named Henry Bagman, who subsequently died. Mr. Astley, for the defence, endeavoured to show that the evidence had failed in proving the charge, and raised some technical objections, which were overruled by the Court. He denied that there was any proof of his client, who was a very respectable man, practising at Ramsbury as a physician and chemist, having compounded the medicine. The jury, however, brought in a verdict for the plaintiffs for 20*l.*, the amount claimed. This is said to be the first case of the kind which has been tried on the merits.

Hydropathy.—Here is Hood's illustration of hydropathy:—It has been our good fortune since reading Claridge on Hydropathy, to see a sick drake avail itself of the "cold water cure," at the dispensary in St. James'-park. First wading in, he took a "Fuss bad;" then he took a "Sits bad," and then, turning his curly tail up in the air, he took a "Kopf bad." Lastly, he rose almost upright on his latter end, and made such a triumphant flapping with his wings that we really expected he was going to shout, "*Priessnitz for ever!*" But no such thing: he only said, "*Quack! quack! quack!*"—*County Paper.*

Anatomy of Suicides.—A writer in the *Annales d'Hygiene*, who has examined about 9,000 judicial inquests of Paris, from 1796 to 1830, thinks himself warranted in assuming—1. That philosophical or premeditated suicide takes place in the night, or a little before daybreak. 2. That accidental or unpremeditated suicide takes place during the day; because it is then that the occasional causes occur, such as quarrels, bad news, losses at play, intemperance, &c. At every age man chooses a particular mode of committing suicide. In youth, he has recourse to hanging, which he soon abandons for fire-arms; in proportion as his vigour declines, he returns to his former mode; and it is most commonly by hanging, that the old man perishes, who puts an end to his existence.

Horrible Specimens of Humanity.—African travellers have spoken of a tribe of negroes who possess that ornamental appendage so much admired by Lord Monboddo, *a tail;* but their statements have never received credence. It appears, however, that a race of men with tails really does exist in the interior of Africa. In a recent sitting of the Academie des Sciences, M. de Couret related that in 1842 he found in the service of a friend at Mecca one of these wretches, the lowest assuredly of mankind. The creature had an exterior prolongation of the vertebral column to the extent of three or four inches. He stated that he belonged to the tribe of the Ghilanes, whose territory is situated far beyond the Sennar, who are thirty or forty thousand in number, worship the sun, the moon, the stars, the serpent, and the sources of a great river, (supposed to be the Nile,) to which last they immolate victims. They eat plants, roots, fruits, and raw flesh, and like it bleeding. Are very partial to human flesh, and eat the bodies of their enemies, of all ages and both sexes, whom they may slay in battle! They, however, prefer the flesh of women and children as more succulent. They rarely exceed five feet in height, are ill-proportioned, with long, thin bodies, long arms, longer and flatter hand and feet than the rest of human kind, have the lower jaw large and long, the forehead narrow and excessively retreating, the ears long and deformed, the eyes small, black, brilliant, the nose large and flat, the mouth large, the lips thick, the teeth strong and sharp, the hair woolly, but not abundant. The man examined by M. du Couret had been so long in slavery as to have forgotten his native language; but he stated that, notwithstanding he had done all in his power to subdue the savage appetite, he was twice a week seized with a rage for raw flesh, which his master satisfied by giving him an enormous lump of mutton, and that if this were not done, he felt that he could not refrain from slaying and eating a woman or child. M. du Couret says that the natural dispositions of this animal were good; that his fidelity to his master was striking; and that he was not without intelligence; but in the slave-markets of the East, where the race is not unknown, they are considered detestable.—*Literary Gazette.*

A Memorial from the inhabitants of Lambeth has been presented to the Central Board of Health, which bears the signatures of His Grace the Archbishop of Canterbury, five surgeons of the neighbourhood, and other inhabitants, against the frightfully-increasing nuisances therein set forth.

MORTALITY TABLE,
(Metropolis)
For the Week ending Saturday, Sept. 1, 1849.

Causes of Death.	Total	Average of Five Summers.
All Causes	2796	1608
Specified Causes	2794	1606
Zymotic (or Epidemic, Endemic, and Contagious) Diseases	2069	802
Sporadic Diseases		
Dropsy, Cancer and other Diseases of uncertain or variable seat	52	54
Tubercular Diseases	166	170
Diseases of the brain, Spinal Marrow, Nerves, and Senses	185	179
Diseases of the Heart and Blood vessels	33	29
Diseases of the Lungs, and of the other Organs of Respiration	94	81
Diseases of the Stomach, Liver, and other Organs of Digestion	72	70
Diseases of the Kidneys, &c.	5	11

TO CORRESPONDENTS.

Many thanks to "Justus" for his communication. We regret, however, to be obliged to decline his kind offer, since we cannot use it in the manner he suggests.

"Cod Liver Oil."—A valued friend at St. Andrew's informs us, he has found, from extensive experience, the mode of administering Cod Liver Oil most successful in removing all unpleasant after effects as two drops of medicinal prussic acid in the water in which the oil is given.

"A Correspondent" inquires the best mode of inspissating the fresh juices of medicinal plants, and of concentrating fluids generally. We strongly advise him not to make the attempt. It is time thrown away, labour lost, and disappointment gained; and, without any undue preference, we have great pleasure in referring our Correspondent to Mr. Hooper, of Pall-mall East, in whose laboratory he will find most efficient arrangements for inspissating juices, concentrating fluids, and drying plants, which, by means of a current of dry air, produces evaporation more speedily than by the ordinary agent of high temperature.

"Curiosity."—There is no law to prevent a member of the College retailing drugs.

"Pharmacien."—Scientific individuals differ as to the various species of Cinchona which correspond with the different kinds of bark.

"A Country Medical Pupil."—Parisian Hospitals are recognised by the College of Surgeons.

"An Old Surgeon."—It possesses the same virtues as the sulphate.

"F.L.S., Southampton."—1 The Prussian Apothecaries receive a liberal education, and are protected by Royal Charter 2 The business of a druggist is carried on separately from that of the apothecary

"Auctor."—The disease more frequently attacks individuals of the sanguine temperament, with light or red hair and next to these, the melancholic but it attacks in its more unmanageable forms persons of a strumous habit, with dark hair and eyes, and a fair skin It is less frequent in women than in men

"M D, Edinburgh."—It would be necessary to obtain the license of the London College of Physicians

"M R C S."—Quinine was discovered by Pelletier and Caventou

"Medicus."—A coroner's inquest should have been held, as there is no doubt the quack treated the case improperly.

"Young Physic."—1 Oxalate of lime is generally diffused through the urine mechanically suspended with lithate of ammonia 2 Dr Venables recommends the following process:—Heat in a flask a portion—an ounce or two—of the turbid urine so that all the lithate shall be dissolved; throw the whole upon a filter, and let the urine pass through while hot The oxalate of lime will remain upon the filter, and may be washed all the sides to the apex by a fine stream of pure water from a pipette If crystalised lithic acid be suspected, it may be washed by a warm diluted solution of potass, or a warm solution of the carbonate The oxalate will be accumulated in the apex of the filter This is to be opened out, and if a feather or camel's hair pencil be applied to the filter, a number of the crystals of oxalate of lime will adhere and may be transferred, by mere contact to the glass slide for microscopic examination On the urine having passed through, if the apex of the filter be perforated, the oxalate may be washed into a clean glass, by means of a stream of pure water as before and the oxalate will then be seen in the water This is a very expeditious and satisfactory process

"Galen Secundus."—Ægophony is a sound peculiar only to the presence of a small portion of effused lymph between the surfaces of the costal and pulmonary pleura, the result of pleuritis It is not heard when the effusion is copious but it is again observable when the effusion is in the course of absorption.

"Chirurgus, Boston."—Gastric irritation will excite uterine contractions after parturition but during pregnancy there may be great sickness without disturbing the fœtus

"A Obscenus."—Matriculation is necessary before entering with any Professor in the University

"On [illegible] to Commence Medical [illegible]."—The Royal Infirmary Edinburgh contains about 500 beds the fee for a year's attendance on the surgical practice is between £ and £

"Hom Medicus."—The several Boards mentioned require the Apothecaries' certificate

"G. B. L."—Malacosteon is another term for mollities ossium

"Quærens."—Since the Report made by the Metropolitan Commissioners in Lunacy to the Chancellor in 1844 two Acts of Parliament have passed, and are now in force,—the one for regulating the care and treatment of lunatics generally, and the other for the provision and regulation of lunatic asylums for counties and boroughs, and the maintenance and care of pauper lunatics therein.

"Oupper."—The formula for chloral is $C_4\ Cl_3\ O + HO$; for chloroform, $C_2\ H\ Cl_3$.

"Phis."—According to Liebig, the increased heat depends on an unnaturally rapid tranformation and oxidation of the animal tissues

"An Old Friend."—The best plan is to take some matter and inoculate Pus taken from a bubo, however, when first opened, may not cause chancre by inoculation

"F. G."—Marshe's test is one of great delicacy. Metallic deposits have been said to have been procured with only a 200,000,000th part of arsenic in the liquid.

"A Medical Practitioner" need not fear an examination at the College of Physicians. Some preparation, of course, will be necessary, though a candidate may have had "long experience in the profession."

"Senex."—A kilogramme is rather more than 2lbs. 3½oz. avoirdupois.

"Philo-Dennan."—Galvanism has been found successful.

"Gregory."—The soap used in medicine is made by boiling to dryness in a gentle heat, 1 part of soda ley, sp. g. 1 33, and two parts of olive or almond oil It is a mixture of margarate and oleate of soda, with free soda and glycerine.

"Dr. Cronin, Leicester place," writes, in reference to Mr. Blanch's paper on dry cupping :—"I wish to correct his misnomer of 'dry cupping.' This confounding the operation of Anaspasia or Traction with one totally different in both its nature and effects, is only calculated to mislead and disappoint Many who read of 'dry cupping' producing such wonderful effects, regard the whole tale as an idle fabrication, and Mr Blanch knows well that he could not have adopted a more effectual plan for disparaging and depreciating a most valuable therapeutic agent, than by designating it 'dry cupping,' a plan adopted invariably by those jealous or envious of its success."

"A Young Student, South Molton street."—Lallemand's Work translated by Mr M'Dougall.

"Studens."—The apprenticeship must be for five years,—not less Our correspondent should endeavour to make some arrangement with his master, without this there will be great difficulties in the way of being admitted as a candidate for the License.

"M.D., St Andrew's," says :—"Few persons are aware of the nature of the examination, or by whom conducted at St Andrew's. When I was in Edinburgh, preparing for it, I mixed with men, who were studying for other Universities, and had ample opportunities of ascertaining their capabilities and I feel assured that some of those who got through at Edinburgh would have been rejected at St Andrew's I do not, of course wish to disparage the former, as I think most highly of the School in all respects but to vindicate the latter as a place of examination

"An M D and Subscriber."—A degree from the University of Glasgow is a sufficient qualification for an assistant-surgeon in the East India Company's service The candidate is also required to undergo an examination by the Company's examining physician (2) The assistant's pay is equal to that of a lieutenant. (3) On applications at the East India House

"Mr C Smith, R N, Sheerness."—A letter had better be addressed to the Secretary of the Society

"Mr I H Leighton, Llandilo," says :—"In cholera, the alkaline principle, which should combine the watery and fatty matters in the system together seems to be destroyed to renew this, I beg to suggest the following mode of treatment :—The patient to be sponged all over, except the head and face, with a solution of muriate of ammonia, the body to be then dusted with pure lime, and closely covered up, to confine the ammonia, disengaged, to act upon it Oatmeal gruel, with plenty of salt in it, to be given copiously to drink." Our correspondent's proposition has certainly the merit of originality We fear however, that what with lime and ammonia, the patient would get into a pickle

"A Young Practitioner." It would be difficult to say.

"Mr Thos Pryer, Artillery place," writes us, in reference to the trial of Griffiths v Walford published in this Journal, that the plaintiff did not expressly apply for a dose of the fluid magnesia and that the defendant did not administer him a dose of Epsom salts In the report, two points are omitted the first is, the particulars of the plaintiff's demand showing the sum he sought to recover; and secondly, the amount of the verdict which he actually obtained The plaintiff endeavoured to obtain £15 [illegible] the jury gave him 5s., which entitled him to 3s 4d costs

"Mr Muggeridge" should not have given a certificate of cause of death if he wished an inquest to be held on the body

"A General Practitioner" writes, in reference to the treatment of Cholera, as follows :—"The chief characteristic of my plan consists in the exhibition of saline purgatives combined with the calomel and opium usually given and I proceed as follows :—℞ Hyd. Chlorid gr v (ad viij) Pil Sapon c Opio, gr vj (ad x) M ft. Pil ij statim sumendæ ℞ Magnes Sulphat ℥j, Magnes Carbon, ʒj, Aq Menth Piper, (fort.) ℥viss Tinct. Opii, ʒj, (ad ʒij) M Sumat Coch. ij Mag. 4tis horis, vel frequentior The rationale of this plan is, that, supposing the profuse serous discharge or hæmorrhage, as it has been termed from the bowels, to be produced by a pathological condition of the exhalents, diametrically opposite to that which obtains under the stimulating influence of a purgative salt, I consider such to be the remedy obviously pointed out as the one best calculated to remove the condition upon which this most fatal symptom depends. Moreover, practice confirms this, for we almost invariably find, that where purgative salts, especially when combined as above are given in English cholera, with a view to the removal of offending matter from the bowels, the opposite effect is produced, the vomiting and purging generally ceasing after the first dose."

"G. W. Balfour."—Received.

"Dr J Pearson."—Received.

PRACTICAL TOXICOLOGY.
SHOWING THE APPLICATIONS OF CHEMISTRY TO THE DISCOVERY OF CRIME.

By H. LETHEBY, M.B., Lond:
Lecturer on Chemistry at the Medical College of the London Hospital.

LECTURE VII.

Mode of detecting sulphuric acid in the fluids and secretions of the body, as of the blood, peritoneal fluid, urine.—Amount of sulphuric acid in normal urine.—Increased quantity of acid passed by the kidneys in a case of poisoning.—Detection of sulphuric acid on wood and articles of clothing.—Effects of the acid on coloured garments.—Care requisite for the examination of the stain.—Illustrative cases.—Sulphuric acid a normal constituent of certain fabrics.—Experiments and cases showing the time that the acid will remain on cloth.—Mode of proceeding when the substance has been washed.—Sources of fallacy.—How they may be avoided.—Dependence that may be placed on well-conducted chemical experiments.

GENTLEMEN,—During the last lecture, we were occupied in considering the modes in which sulphuric acid is to be recognized in organic mixtures; we will, if you please, continue our inquiries into this subject.

(c.) *Method of detecting Sulphuric Acid in the fluids and secretions of the body.*—In cases of rapid death from the effects of oil of vitriol the acid may generally be detected in the fluids of the peritoneal cavity; for, as Dr. Christison first remarked, the poison quickly transudes through the walls of the stomach and intestines. So, again, it may often be discovered, in the blood of the mesenteric and portal veins, and in the small coagula which block up the vessels of the stomach. Dr. Christison lays great stress on this fact; for he says, that "an important appearance in the abdomen, to which less attention has been hitherto paid than it deserves, is gorging of the vessels beneath the peritoneal membrane of the stomach and adjoining organs with dark, firmly coagulated blood, arising from the acid having transuded through the membranes and acted on the blood chemically. My attention was first turned to this appearance by an interesting case which I saw in 1840 in the Royal Infirmary of this city, and of which an able account is published by Dr. Craigie. The whole vessels of the stomach were seen externally to be most minutely injected and gorged, and the blood in them was coagulated into firmly cohering cylindrical masses, as if the vessels had been successfully filled with the matter of an anatomical injection. This appearance was also observed in the superior mesenteric arteries, in the omental vessels, and over the greater part of the mesentery. It was occasioned by the chemical action of the acid coagulating the colouring matter and albumen; for the clotted blood was strongly acid to litmus paper. So, too, was the peritoneal surface of the stomach, omentum, and intestines. And the acid had transuded through the stomach and into the omentum and tissues of the intestines during life; for, in the first place, there was no perforation of the stomach; and, secondly, I ascertained, that there was no free acid either in the matter discharged from the stomach before death, after the free administration of antacids, or in the contents of the stomach obtained at the examination of the dead body." I would not, however, advise you to form any opinion upon the evidence which may be derived from the detection of sulphates in the blood removed from any other part of the body.

Again: an examination of the renal secretion may, perhaps, furnish you with very satisfactory proof of the administration of the poison; but you must remember, that, during the natural and healthy state of the body, the urine always contains a certain proportion of sulphuric acid in the form of alkaline sulphates. This acid is, in all probability, derived from the sulphur of the wasted and broken-up tissues, and its proportion in the urine varies from about 0·1 to 0·4 per cent. The following Table exhibits the amounts of sulphuric acid detected in the healthy renal secretion by different chemists:—

	Per cent. of sulphuric acid.
SIMON:—	
1. Normal urine	0·161
2. Morning urine on rising	0·128
3. Urine passed directly after active exercise	0·101
4. Urine passed half an hour after active exercise	0·23
BERZELIUS	0·348
LEHMANN:—	
1. Urine of 24 hours	0·37
2. " "	0·369
3. " "	0·37
DUMERIL	0·13
BECQUEREL, mean of 8 analyses ..	0·086
MARCHAND:—	
1st analysis	0·336
2nd "	0·317

And with the view of verifying these results, I have myself made a few examinations of healthy urine, and have found that the sulphuric acid contained in it varies from about 0·024 to 0·23 per cent., as the following Table shows:—

When passed.	Amount voided.	Total quantity of acid in it.	Per centage quantity of acid in it.
9, a.m.	℥vij.	7· 6 grs.	0·226
1, p.m.	℥ij. ʒvi.	0·48 "	0·036
9, a.m.	℥xx.	12· 3 "	0·128
1, p.m.	℥v.	1·88 "	0·078
3, p.m.	℥viij.	0·95 "	0·024
SECOND INDIVIDUAL.			
8, a.m.	℥x.	10· 2 grs.	0·212
From 8 p.m. to 8, a.m.	℥xxxj.	19·14 "	0·128

In cases of poisoning by oil of vitriol, however, the quantity of sulphuric acid contained in the urine is much greater. In fact, in one case of this description, which came under my notice, that of a little boy, nine years of age, who had, inadvertently, swallowed sulphuric acid, I found that the urine which was voided on the first day, after taking the poison, contained as much as 50·8 grs. of anhydrous acid; that on the second day contained 32·7 grs.; that on the third day, 14·9 grs.; and that on the fourth day, 10·4 grs.: so that, in all, I collected 108·8 grs. of anhydrous sulphuric acid,—a quantity equal to 133 grs. of the monohydrated acid, or to about one ounce and three quarters of the dilute acid of the London Pharmacopœia. I have noticed, moreover, that when sulphuric acid, or a sulphate, is administered medicinally, the remedy is eliminated, in great part, by the kidneys. In fact, I have, in this way, been enabled to raise the per centage amount of sulphuric acid voided in the urine, from 0·12 to 0·4, in the course of a few hours.

Having these facts before you, it is highly necessary that you should make an analysis of the renal secretion, in all cases where you suspect that oil of vitriol has been administered; but you are not to forget that while, on the one hand, the evidence derived from such an inquiry may be of considerable importance, so, on the other, apart from any collateral proofs of the action of sulphuric acid, it is not of much value; for, as I have before said, the exhibition of a sulphate will give rise to the very same series of results.

(d) *Detection of Sulphuric Acid on Wood and Clothing.*—In most cases of poisoning by oil of vitriol, a portion of the acid will be thrown about; and, falling upon the floor of the apartment, or upon the clothes of the individual poisoned, it will furnish very valuable evidence as to the nature of the case.

When this corrosive liquor drops upon wood, it discolours and carbonizes the ligneous tissue, and leaves a damp spot, from which the acid may be removed by simply digesting the organic substance in a little distilled water.

So, again, when strong oil of vitriol has been spilt upon linen cloth, it will char the fabric and rapidly corrode it. Even a weak acid, which has a density as low as 1140, will act upon these vegetable tissues, and, by converting their cellulose into sugar, will produce a damp, fragile, and very soluble compound.

Lastly, with regard to the action of sulphuric acid upon woollen fabrics. I have already shown you, that these articles of clothing are powerfully acted upon by the acid in question,—that they are, in fact, discoloured by it, and made damp and rotten.

Should any of these substances have been dyed, the acid will, in all probability, act upon the colouring matters, and produce effects which can be readily distinguished. Mr. Taylor has discussed this matter so clearly, that I shall quote his observations upon the subject:—"If the dress be dyed blue with indigo, the colour will be unchanged; if dyed with archil, and some other blues, the spot may be reddened, and red streaks will be found wherever the acid matters have passed over the dress. Logwood and madder, which are largely used in dying many of the common calicoes, are turned of a yellow colour by strong acids; and wherever an iron mordant has been employed in the pattern, there will be a rust-red spot. In a very diluted state the acid is slow in acting, and the stain, when recent, is red. I have found, by experiment, that whether the acid be used in a pure state, or darkened by organic matter, the effect is the same; and it would be impossible to say whether the colourless, or coloured, (carbonized,) acid has been employed for the purpose of producing it."

The stains, therefore, produced by sulphuric acid, are very important facts for your consideration; but you must not be guided by them alone, and you must also take great care that you do not confound them with discolourations produced by other causes, as the following instances will show:—

In a case alluded to by Mr. Taylor, a prisoner was charged with the murder of an infant, by thrusting some corrosive substance into its mouth. "The witnesses for the prosecution deposed, that they saw the prisoner put something, of a pink colour, into the child's mouth; that the child was then sick, and vomited over its own dress,—some of the liquid falling upon an apron which the prisoner wore. There was no proof of poisoning, but these spots were considered to bear strongly against the prisoner. On examining them, says Mr. Taylor, I found that the dress of the child had been dyed with cochineal pink; that the stains were of a crimson colour, and not corroded: the apron worn by the prisoner was died with madder-purple; the spots on it were small and circular, not lengthened, like those which would be produced by the act of vomiting; the dye was changed to a *yellow*, and the fibre corroded. It was, therefore, clear that the spots on the child's dress had been caused by *an alkali*,—those on the apron by *an acid*; consequently, they could not have been produced at the same time, and from the same cause.

A case of a like description, in which a careful inquiry into the nature of some spots found upon a man's coat tended to annul a criminal charge, occurred in my own practice in the summer of 1848. A gang of thieves had been committing numerous depredations in the neighbourhood of Ilford, and had for some time defied the vigilance of the police. One night, however, the plunderers were disturbed in their operations, and one of the thieves, in order to effect his escape, threw himself from a high window. By so doing he was cut and bruised very much, and it is believed that he was rendered insensible, for his comrades took him up, and effected their escape. Blood flowed freely from his wounds, and, upon instituting a search among the suspicious characters of the neighbourhood, a man was found whose coat appeared to be stained with a sanguineous fluid; but, on making a careful examination of the garment, I discovered that the red spots, supposed to be blood-spots, had not been produced by the fluid in question, but by a solution of sulphuric acid—a fact which was sufficient, there being no other proof of guilt, for an acquittal of the prisoner.

The process whereby you will succeed in detecting the presence of free acid in such organic substances, is the following:—Cut out the spot pro-

duced by the questionable matter, apply it to your tongue, and notice if it have a sharp acid taste. Then moisten the substance with water, press it upon a piece of litmus paper, and observe whether it stain the paper of a red colour. Lastly, digest the substance in about thirty drops of water, and test the solution so obtained with chloride of barium and nitric acid.

By proceeding in this manner, you will generally succeed in recognizing the presence of the free acid, notwithstanding that a considerable period may have elapsed since the tissue of the organic compound became impregnated with it. In the course of some experiments which I made last summer, I found that, when fifty grains of a liquor containing 10 per cent. of sulphuric acid, were dropped upon a piece of linen cloth, and then set aside for a period of six weeks, I could readily dissolve out about 4·5 grains of the original acid. Similar results were obtained when I used a stronger or a weaker acid; and I noticed, also, that, when fifty grains of this acid liquor were thrown upon a piece of woollen cloth, and allowed to act for the same period, I could, by washing the flannel so treated, recover about 3·9 grains of the acid first used. These experiments are confirmatory of results obtained by other toxicologists; for Dr. Christison, in referring to the case of Macmillan, which was tried in Edinburgh in the year 1828, says, that "Dr. Turner and I, who were employed by the Crown to examine the different injured articles of dress, found on the man's hat, stock, shirt-collar, and coat, many discoloured and corroded spots, which were sour to the taste fourteen days after the crime was committed. In the subsequent case of Mrs. Humphrey, I discovered six-tenths of a grain of free sulphuric acid in two small spots on a blanket seven weeks after the crime; and, from an express experiment on the same blanket with two drops of acid of known strength, it appeared that only one-half of the acid disappeared in seven weeks." And, says Mr. Taylor, "I have ascertained by experiment, that sulphuric acid may be easily detected on articles of clothing after many years' exposure (to the air). In January, 1831, a small quantity of this acid was spilled on a black cloth dress; it has been exposed in an open jar to the air for upwards of sixteen years. The cloth is changed to a deep brownish black colour; it is soft, and yields to water a brownish-coloured acid liquid, in which a large quantity of sulphuric acid may be still easily detected. In a case of poisoning, which occurred in 1832, the acid was partly spilled on a dress of printed cotton. This," continues Mr. Taylor, "has likewise been exposed for fifteen years; the organic fibre is completely corroded by the acid, and reduced to a kind of humid powder; from this substance, by the addition of water, a liquid is obtained, the acidity of which is proved by the barytic test to be due to the presence of sulphuric acid. These facts are of some interest, because it has been generally supposed, that the stains on clothing soon lose all traces of the acid, partly by decomposition in contact with organic matter, and partly by evaporation; but it is hereby evident, that such stains, if not removed by washing, may be, in some instances, detected for a period of time much longer than is ever likely to be required in any medico-legal investigation." I have quoted these remarks made by Mr. Taylor, because I consider them to be very applicable to our present inquiry.

In the conduct of these investigations, you must not, however, lose sight of the fact, that many articles of dress normally contain sulphuric acid in consequence of their having been treated, during their manufacture, with some sulphate, as alum or copperas. A case illustrative of this was referred to by Dr. R. D. Thompson, at the Glasgow meeting of the British Association in 1840. A woman had, in a fit of rage, thrown some oil of vitriol in the face of a cab-master. Some of the acid fell on his hat, and Dr. Thompson was requested to examine this article of dress. The results of his experiments showed that the injured hat, as well as an uninjured one, contained sulphuric acid; for the solutions derived from each of them reddened litmus, and gave a white precipitate with nitrate of baryta. Dr. Thompson concluded, therefore, that in prosecuting inquiries of this sort, it is necessary to make a quantitative examination of the sound fabric, in conjunction with that which has been stained by the questionable liquor, and then to compare the results obtained in the two cases. In his analyses he found that the uninjured part of the hat contained 0·356 per cent. of sulphuric acid, while the stained portions of it contained as much as 1·379 per cent. of the acid, showing that the injured parts had received 1·023 per cent. of free acid.

It may, happen, however, that the fabric or tissue upon which the acid has fallen, has been washed, and so deprived of the greater portion of the poison originally contained in it; but this you will also be enabled to determine; for, to say nothing of the fact, that both the colour and texture of the part will be considerably altered by the operation of the vitriol, a portion of the acid is almost sure to remain in the tissue in combination with its organic elements; consequently, if it be a vegetable substance, such as wood or linen cloth, upon which the vitriol has fallen, we have but to dry the suspected matters, and subject them to heat in a small test tube, in order to prove that they have been acted upon by the poison in question; for, if sulphuric be present in ever so small a quantity, it will be decomposed by the combined action of heat and organic matter, and the resulting empyreumatic vapour will have the property of rendering blue a piece of paper, moistened with starch and iodic acid, held over the mouth of the tube. This process, however, although it is extremely delicate, and particularly applicable to the detection of sulphuric acid in the commoner kinds of vegetable substances, is utterly valueless when we are operating upon matters which naturally contain sulphur, as, for example, bread, wool, hair, silk, leather, &c. Under these circumstances we cannot come to any positive conclusion as to the presence or absence of sulphuric acid, unless we make quantitative analyses both of the sound and injured parts of the substance, and compare the results; for, as I have already shown you, when oil of vitriol is brought into contact with any kind of protein compound, the acid enters so firmly into union with this organic principle, that it cannot be removed by any ordinary process of washing. Take, therefore, a given weight of the suspected tissue, wash it with water, and dissolve it by heating it in a little of the nitro-muriatic solution before-mentioned. Filter the liquid so obtained, and precipitate the sulphuric acid contained in it, by means of any soluble salt of baryta. Treat a like portion of the normal tissue in a similar manner, and, after separately igniting the two products, and then weighing them, you will be enabled to determine whether the suspected tissue contained an excess of sulphuric acid or not. I have ascertained, by experiment, that sound and clean flannel yields about 3 per cent. of sulphuric acid when it is treated in this manner, and that a woollen cloth which has been acted upon by oil of vitriol will yield from 4 to 10 per cent. of this acid.

By proceeding in this manner, you will be enabled to remove many doubts which might otherwise hang over your investigations, and perhaps solve many problems which the ordinary modes of medico-legal research, as regards this poison, are totally incapable of unriddling. Some authorities may, perhaps, regard these methods of inquiry as among the dangerous refinements of toxicological research, and say, that it would be perilous to found an opinion upon evidences deduced from such critical methods of investigation, seeing that, on the one hand, there are so many sources of fallacy, and, on the other, the serious consequences which may result from a wrong conclusion. Acting, therefore, upon a legal rather than a scientific dictum, they are ever for avoiding such dangers, and giving the prisoner the benefit of their doubts. But, Gentlemen, I regard these doubts and fears as false and unnecessary. I have, in fact, too much confidence in the results of a well-conducted chemical operation, to entertain them even for a simple moment. And you yourselves cannot too well remember, that chemistry is strictly an exact science, and that its results are always certain; that, in fact, you can only fail in your inquiries, and apparently fail in your results, when you despise that trouble and care which are registered among the most important of her rules; and you may believe me also, that no man is fitted for the performance of such momentous operations, or for the serious duties of a toxicologist, when he gets to think that a chemical process is too "operose," because it involves trouble, or "too refined," because it requires nicety and care.

It was my intention to have gone on to-day to the consideration of the impurities of oil of vitriol, and of the modes in which they are to be removed for medico-legal and other purposes; I intended also to have spoken of the fraudulent uses of sulphuric acid and its salts; but, as our time is nearly expired, we must leave these subjects for consideration in our next Lecture.

LECTURES
ON THE
PROCESSES OF REPAIR AND REPRODUCTION AFTER INJURIES.

DELIVERED AT THE

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

By JAMES PAGET, F.R.C.S.

Professor of Anatomy and Surgery to the College.

[Reported for the "Medical Times."]

LECTURE VI.

Repair of Muscles and Tendons, divided in open and subcutaneous sections.—Inflammatory effusion following the injury; effusion of reparative material; its organisation and gradual perfection.—Repair of divided nerves: the primary and secondary conjunction of their fibres.—Repair of skin: reproduction of its papillæ and epidermis.

Mr. President and Gentlemen,—My concluding lecture will be but fragmentary, consisting of the consideration of the modes of repair of fractures of the several tissues. In the former lectures I have enumerated the several parts which are capable of complete repair, and which may be divided into three classes. 1. Those in which the several elements are formed by a repetition of the first mode of formation; those which accord with the plan of nutritive repetition, in which the reproductive power is most distinct. 2. Including those which are of the lowest organic tissues—having all their bases of gelatinous matter. 3. Those which exist as parts of the tissues destined to connect it—nerves and bloodvessels. But, with these exceptions, all other parts can only be repaired; some other material is inserted in its place, and, among these, we shall only select those to which facts of interest attach.

And, first, as to the repair of cartilage. Perfect cartilage seems never to be reproduced, but is repaired with only fibrous tissue. Here is a specimen taken from a man who had cut his throat; the wound was made by a razor, and the microscope shows that there was not the smallest reproduction of cartilaginous matter. And one fact is observable here,—the very little change in the seat of the injury, after such a clear cut, for it showed characters which one could not discern from a section of perfectly healthy cartilage. Sometimes it happens, that injuries of the cartilages are repaired by osseous matter; this is seen with respect to fractures of ribs; but when this is the case, I think it should be taken that the cartilage rather degenerates into it. The repair of tendons is of peculiar interest. I have before quoted Hunter, where he says that wounds which are not exposed to the air seldom inflame. Now, here we have one of the few instances in which the discoveries of science have not been made use of in art. Hunter proved that subcutaneous operations were practicable with regard to the division of tendons. Experiments prove that the disadvantage of a section of external opening are, that the inflammatory process is of much longer duration and more acute; so that the lymph may be formed, or a process of suppuration may ensue. The permanent inconvenience is that one substance is formed for all the parts divided, and hence there is an absence of that

pliancy on the tendon which there was before. Besides, in open wounds of tendon, there is much greater liability to retraction of their ends. Now, these disadvantages are not commonly observed where the wound is speedily healed; for, if this does not take place, the process would go on as it does in a subcutaneous wound. Then it is necessary to do it merely under the skin; for, if it be done on the open wound in the tendon, the healing would ensue by the same process as that which follows in subcutaneous section. (Diagrams were here exhibited, illustrating the process of healing of subcutaneous section, 10 and 21 days after.) All these were made after instances of subcutaneous section; and are enough to prove that the repair of tendon does not depend on whether the section be made through the sheath or not; all these were made through it, and went on as well as if the tendon alone had been cut. One of the effects produced here is retraction of its end connected with the muscle. In healthy animals this retraction of the muscle extends to about one inch. The first effect of this is, that of infiltration of the inflammatory matter into the tissue between the retracted ends of the wound. This is simply inflammatory matter, and takes place through the whole extent; much collapse of the skin is not discernible. This, in ordinary cases, does not continue more than forty-eight hours. In the best specimens of repair it does not increase. Instead of increase, there ensues an infiltration of a different material—a material which has the character of simple fibrine of the blood, and in its solid state. This is formed so that it sheaths each end of the tendon, and is so deposited as to embody whatever remains of blood may be found there; and then a clot of blood may be enclosed. What is the definite design of this? The first inflammatory matter is diffused uniformly, but this is deposited no where but in the line where the repair is to be performed, just as in repair after fracture. Subsequently there is a deposit of new material; in its first production this is simple fibrinous matter, but ultimately acquires a more defined outline. Here (diagram) its margins are sometimes indefinite; in others there is a distinct cord; but within five or six days it will so far show a structure, having the characteristics of nucleated blastema, which will arrange and develope themselves so as to assist in the production of tendinous tissue. How much more energetic is the reparative process in the early stage of an injury! By the tenth day the material becomes paler, is apparently less vascular, and its tissue has a distinct filamentary character. Within three weeks it would form a perfect and continuous cord, very nearly resembling a cure. Then the parts which surround the new material are gradually more and more approaching recovery. And here it is strange to notice the distinct purpose manifested. While the new material is being developed, the other gradually degenerates. In like manner, one may notice the changes in the retracted ends of the tendon, or, rather, in the upper end. This is the reason why the reparative process is more perfect in the upper part; it is drawn far beneath the reach of the healthy tissues. There is one change to be noticed here,—a slight swelling, with softer contents, four or five days after the injury; and if this is examined by the microscope, it will be seen to depend on the effusion of filamentary matter between the filaments, so that it acquires a holdfast on the tendons. The same development ensues in the reparative materials, so that finally one gradually sees the substance of the tendon merging into the substance of the connecting cord. With regard to the reparative process in animals, there may be as much difference in the human subject and in animals, as in bones. But the difference is only slight, and in degree. But as it respects tendons the plan of repair is just the same. Here is a specimen which would warrant us in saying that the difference is very small—in a child seven years old, where the tendon Achillis was divided, and the repair here corresponds with that in rabbits. In the human subject the new material is formed upon a perfect imitation of the original structure. Mr. Tamplin has presented to the College three specimens, from a child five weeks old, of a cutting of the tendon, and which died nineteen months after the operation. On examination after death it was really impossible to discover the parts where the division was made, or to tell where the substance of the old tendon ended. When the new tendinous structure does not acquire the marks of the original structure, it is yet found to be capable of it; and I have made experiments to test this power in the new material. I took a specimen six days after the division of the tendon, and only four days of the six were occupied in the organism of the new substance, and yet it could then bear a weight of twenty-five pounds; and, in another case, by gradually increasing the weight, in twenty-one days the new material bore fifty-six pounds weight, and yet it was so organised and compacted, that after bearing a weight of forty-five pounds, it at last rent down under half a hundredweight. The repair of muscles corresponds with that of tendons. The muscles were divided at the tibialis longinus; the first efforts consisted in effusion of inflammatory matter between the ends; but a longer interval elapses before the existence of the reparative material; in muscles it is generally five, six, or even seven days. It is, in the first instance, always produced from the deepest part of the wound. The terminations of the muscular fasciculi are sunk down into the deep parts; these ends always become imbedded in the inflammatory material; and this accumulating, would pass through its several changes, gradually assuming, more and more, the character of perfect tissue. There are no instances in which transverse or muscular fibre has ever been produced in animals. I believe it is most certain that true striated fibre has never. There is a process which deserves remark, viz., its contraction; it may draw the ends of the muscle nearer to each other. In the case of cut throat the muscles had contracted, but they were drawn into perfect contact. A further step consists in the loosening of the bond of union which connects the parts, and sliding uniformly on the adjacent parts.

In the union of nerves, in most cases, repair moves by a series of changes corresponding to that in tendons. This has been demonstrated through specimens presented to the College and by drawings which display the exact manner in which they are fastened to the bone. But then there ensues in the new material, a further process of development, so that there may begin to be formed in it perfect new nerve filaments; and thus, after a long period from division of nerves, there takes place a connexion between them. Mr. Hunter obtained a view of this process, where he took a nerve from a stump, dissected it, and carefully traced into it filaments of nerves, passing for some distance into it; and also in a horse's foot, in which the sensation of the foot was restored, by the formation of a new connecting substance. Here, in the human subject, is a specimen, where, in three or four months, sensation was restored to the leg. But we need hardly now dwell more on this process, as it has been so fully described by others. We had a case in Bartholomew's Hospital, of a boy, who had a wound extending transversely across the wrist, dividing the radial artery, and cutting into the radius. That the Median nerve was divided was certain; and the question was discussed as to amputation. This was decided negatively. The parts were placed in contact; and within ten days the boy manifested distinct evidences of sensation about the fingers, and in three weeks very distinct general sensation. The remaining loss of this faculty was just enough to prove the imperfection of the union which had been made; in parts between the fore-finger and thumb he made mistakes. Without doubt, in this case, the ends of some filaments had become connected with the ends of others. When this happened, another occurred to me, in a boy who had cut right across the wrist, and where the radius was divided, together with the extensor and ulna arteries and nerves. It was decided not to amputate; it was neatly adjusted, it united, and in a fortnight the boy had distinct sensation, while that which had been imperfect went on improving till it was perfect. These cases are quite enough to justify one in the belief, that this process is more rapid than that accomplished by new fibres. We have no example in which the nerve or ganglia corpuscles have been reproduced.

I might here pass on to the consideration of other substances; but I will only now notice some general considerations; and first, with regard to the relation between the reparative process and other processes. In the process of repair, we may trace the manner in which diseased parts gradually return to their previous perfection. The reparative process is so long that it takes two years for the healing of a nerve; but this is not more than the changes common scars undergo. You do not find the common scar perfect under twelve months old; I have examined scars twelve months old, in which there was no elastic tissue; but within this period we seldom fail to observe some remnants, some cells which hang about the scar. The perfection of repair, then, is accomplished by gradual improvement of parts which replace each other, more after the type which belongs to the perfect individual. As to the relation which exists between the processes of repair and inflammation, we refer to it more out of deference to the opinion which prevails, that there is something like an inflammatory act in the repair of an injury. Now, there are several modes of repair, in which we conclude that the inflammatory process forms no part, as in the repair by immediate union, where, if inflammation does exist, it is hindered. For the repair of subcutaneous injuries, the inflammatory matter is no help; rather, if the inflammation be acute, it is a bar; while we know that that process is produced by a material of a non-inflammatory character. In primary adhesions, and by granulations, we have no inflammation, for this developes itself in the same way as the lymph does. Inflammation is only necessary for the first product; the material, once produced, acquires its characters, in the absence of all inflammation; and the healing of wounds is constantly prevented by accidental inflammation. But then we must inquire whether inflammation is not to be looked upon as a subordinate agent; and here must not overlook the fact, that it is the existence of the power which determines the development of the germ. In all the processes, we can see exact imitations. We recognise this in the lower animals. We must distinguish and mark several points: that, first, all reparative material is organized according to no model or derived from any germ. In any case of repair of tendon, the whole length of the new bond is more developed in the central parts than in the ends; nor is it to be imagined that the succession of germs is to be developed in substance like themselves. Bone is often formed in detached portions, which cut off all exercise of assimilative force. Witness the instances of two modes of development of fibrinous cellular tissue—both like the development of the fœtus—both exact repetitions of the mode in which the bone is first formed. And, again, in the formation of blood-vessels in lips, which is no new thing. Now, where there is a large mass of substance for repair, there are concurrent developments in all its parts. In a layer of granulation cells nothing is more homogeneous. One finds that it is constructed into fibrous tissue; and then, as its last characteristic, notice the limit it observes as to extent, and the mode it pursues. Reconstruction is bound down by the same laws as the construction. One marvels that the hydra multiplies itself fifty fold; but in no case could that have been turned into another species, or grown into an hydra fifty times its bulk. And so we find a perfect nerve, bone, and tendon produced, and none developed into one of a higher form. So, then, whether we watch the method or end of the reparative process, we recognise the identity between the process of repair and of our own production, and, watching this, we gain some idea from it of the essentiality of their living characters; for, when we watch the living being, in these chances of accidents, and see how it is made to deviate from a specific form, we thus have an assurance that the specific characteristics of individuals is determined by properties under the influence of

which these materials develope themselves, according to the same law which ruled in the construction of the species; and we here see that matter is not cast into the world according to its specific characters, but endowed with certain properties which might, by their constancy, bear the very image of their Creator.

ORIGINAL CONTRIBUTIONS.

CHOLERA IN CRAMOND PARISH.

By G. W. BALFOUR, M.D.

During the past year this parish has twice suffered from an outbreak of cholera. Throughout the whole of the autumn of 1848, diarrhœa, dysentery, and British cholera prevailed in the parish. On the 11th October a case of the latter, of a most severe character, occurred. The tongue was cold, cramps severe, and the urine was suppressed and remained very scanty for several days, but the evacuations were bilious from the first; there was no collapse, and the case yielded at once to treatment. The first case of true Asiatic cholera occurred on the 11th of November, and the last of the first outbreak on the 20th of December, between which dates inclusive, 23 cases occurred, of whom 8 died; 10 of these were under 14 years of age, of whom 6 died; 14 of the entire number were under my care, 3 of whom died; 6 of them were under 14, 2 died; the youngest aged 2 years, and the oldest aged 70, both recovered. Only 2 males above the age of 14 were affected, both of them recovered. Two of the women were pregnant; one in the ninth month was delivered of a putrid child, about ten days after her recovery from cholera; the other was in her sixth month, and was subsequently delivered at the full time of a healthy, but small and ill-nourished female child, now strong and healthy enough. At this period the disease was characterised by copious vomiting and purging of rice water, collapse, and suppression of urine; the cramps, through pretty general, were not severe.

The second outbreak of this disease occurred on the 17th of May, and lasted till the 31st, during which period 10 cases occurred and 7 deaths, most of whom were old people, with one or two children. Most of them were under the care of my brother, John Balfour, Surgeon, H.E.I.C.S, who was appointed for the purpose by the Parochial Board.

The disease at this time was characterised by severe cramps. Vomiting and purging not generally severe, and easily checked. The patient, in several instances, apparently recovered, the heat of skin returning, but the tongue and breath continued cold; the pulse did not rally, and the breathing became more and more oppressed till death occurred, which was generally by coma.

THE QUESTION OF CONTAGION.

The first case of the first outbreak occurred at a village connected with the iron-works, on the banks of the Almond, a few feet above the level of the sea, and nearly five miles from Edinburgh, in which city the disease was then raging. No authentic case had occurred in the intervening district, and neither the victim nor her family had had communication with the city for weeks previously; she was a dissipated woman, mother of a family, nursing at the time, and living in a dirty, damp cellar, with but scanty clothing. The second case was the young son of a woman living on the second floor of a house opposite, who, from motives of compassion, had suckled the child of the first victim, yet neither it, nor its foster-mother, nor her own nursing child took the disease. The third case was a younger brother of the second. The next four cases occurred in the same village, one of them being an old woman of 70, who had recovered from an attack in 1832, and was fortunate enough to recover from this one also; she had nursed cases Nos. 2 and 3. The 8th case occurred at Davidson's Mains, forming the solitary one there at that time. The man was a great drunkard, but had no communication with the infected locality. On the same day with him three others were seized at the mills, and another isolated case at Cramond, in the person of a young boy, living in a damp, over-crowded house, and with bowels habitually irregular. The next day, a daughter of the first victim was seized at the mills, and another, a pauper, a little further up the river, in a small hamlet, termed Dowie's Mill, where it proved an isolated case. No case occurred now for four days, when it broke out in a different part of the parish,—at a cottage on the farm of Silverknowes, in the person of a woman, who bore an indifferent character, and had just returned from a drunken ramble of several days' duration. The day after this a woman was attacked at the Burnside, a cottage about ten minutes' walk from Silverknowes. Two new cases likewise occurred this day at the mills, and another isolated one in a cottage standing alone in a field in West Pilton. The disease now ceased for twelve days, when it again broke out in a cottage at Silverknowes, away from the one first attacked—indeed, standing alone. Four days afterwards a child was seized in the same house, and three days after that a woman was seized in a cottage on the neighbouring farm of Lauriston; and four days afterwards the last case in the parish at this time, occurred in a cottage standing alone on the sea-shore, a full mile from any other habitation. This case occurred on the 20th December, 1848; and for nearly five months no case had occurred in the parish; indeed, so far as I am aware, there was not a case in Scotland when, on the 17th May, 1849, two cases occurred in Davidson's Mains. The first was a woman who had not been from home, nor had any stranger near her. She had been engaged in washing the previous day, but only the ordinary clothes of the family. Went to bed in perfect health, and was attacked about one a.m. with profuse diarrhœa. The second case—a boy—was seized within a few hours of the first, there having been no communication. The third case was a woman at Lauriston farm, about half a mile from the village. There had been no communication, but she had been in bad health all winter. The fourth case was a man who assisted the husband of the first victim to carry out the coffin; (a) but he was a dissipated man, had been drinking all the Saturday night, and followed up the funeral with a debauch; he took ill on the Monday morning, and died that afternoon. The next case was a daughter of the woman formerly ill at Burnside, a quarter of a mile from Davidson's-mains, through which she had, the day previous, passed and re-passed, on her way to and from Corstorphine, where she had eaten several apples. She had also just recovered from measles. For five days there were no cases. Then two more occurred in Davidson's-Mains; and, on the following day, other two. It ceased again for three days, when the last case occurred, which, I trust, may be indeed the last in this parish.

My brother, in his Report to the Parochial Board, states, that, "in the village of Davidson's-Mains, with one exception, and that but a slight case, the disease was confined to the north side, and chiefly to the centre of the village, where the houses are crowded by smaller ones behind; a dirty drain, or, rather, gutter, runs in front; while dung-heaps, offensive privies, and other nuisances, were, in too many instances, close to the doors. Some of the houses—perhaps all—were overcrowded, and some possessed no means of making a thorough draft even during the day, while, during the night, the foul air and effluvia from the bodies of the inmates must have rendered the atmosphere sufficiently pestilential." He also adds, with respect to the house at Burnside, which has been attacked by cholera every time it has been in the parish,—viz., in 1832, in 1848, and again in 1849,—that "the well there is very bad, level with the burn which carries down all the filth of the village,—Davidson's-Mains,—and only separated from it (if so at all) by a single row of stones." This said burn also flows past the cottage at West Pilton, in which the solitary case of cholera appeared. The cottage by the sea-shore at Lauriston has also a bad drain in front, and a bad well.

In conclusion, I may add, that the breaking out of the disease in this parish could, at neither period, be ascribed to contagion; that it attacked individuals living widely separate, sparing those in constant communication, except when they were otherwise susceptible, as from bad nourishment, recent dissipation, previous illness, or fatigue from watching, &c. Even in the iron works, where the most of the cases occurred, it jumped from house to house, attacking those who scrupulously avoided all communication with the sick just as freely as those who did not do so. Consequently, its spread could not be ascribed to contagion; and, even in those cases which looked most suspicious, the *varying periods which elapsed between contact and seizure* seemed to point to the agency of other causes than mere contagion. Almost all the inhabitants of the village where it first broke out, are dissipated. The village itself was very dirty, and the houses, especially those in which the disease first occurred, very damp. I may call all very much over-crowded, and, although the existence of local morbific agency could, in most instances, be only vaguely pointed out, still, in others, we had, in the pre-existence or post-occurrence of other zymotic diseases, more conclusive evidence. As in the cottage by the sea-shore at Lauriston, (a mile from any other habitation), the old couple residing in it had both suffered from typhus two months before, and a girl staying with them was only convalescent from small-pox. The old woman had not been out of her own house for three weeks previous to her death from cholera in December, 1848; and, when the disease returned in May, 1849, the old man was seized with premonitory diarrhœa, in which stage it was checked. The cottage in West Pilton, in which a solitary case occurred in December last, has scarce been free of disease since; a case of confluent small-pox having begun the round. Again, the cottage at Burnside, which has been thrice attacked is far from being healthy; all the diseases occurring in it present an erisypelatous tendency. Each time that cholera occurred in it, the other inmates had all more or less of diarrhœa,—and the last time a case of erisypelas of the face occurred three days after the death of the cholera patient. This house also shows the part played by foul air in localizing the epidemic. It consists of two dwellings, the westernmost of which suffered most severely in 1832; but now, being inhabited by a young couple with but two children, it has wholly escaped,—while the eastmost one, being inhabited by a large family,—neither house possessing means of ventilation,—has suffered severely.

A striking example of local morbific agency, assuming the appearance of contagion, occurred in a house forming part of one of the old-fashioned circular steadings, with a dunghill in the middle, in a policy in this neighbourhood. Last autumn, first one case of dysentery and then another occurred, till all the inhabitants—three in number—were seized; two of them died. Almost every one who entered the house had more or less of diarrhœa, and all who stayed a night in it took dysentery. Two women, who had been engaged as nurses, were, to the no small horror of the inhabitants, removed to their houses in the village, where one of them subsequently died of a most virulent form of the disease, in a small ill-ventilated house, where the stench was horrible; and, though well watched and cared for night and day, not another case occurred; while the *origo mali*, the bad dunghill, having been cleaned out, its bed washed with lime, and not suffered to re-accumulate, the house primarily attacked has since then remained healthy. As a contrast, I may mention, the cholera nurses in Manchester, in 1832, who were, at first, worked six hours and allowed to go home other six, the mortality was so bad amongst them that there were fears of the supply failing, it was found that they spent their leisure hours in rather too jovial a manner; they were, consequently, afterwards confined to the Hospital, and not a fresh case occurred amongst them, and

(a) The corpse had been kept from a Thursday till a Saturday, in defiance of the authorities. The husband locked the door in the face of the County Police officer, alleging, as his reason for refusing compliance, that he had issued cards of invitation, and did not like to disappoint his friends. He was tried before the J. P. Court, convicted, and fined.

only two relapses. The whole question of contagion, therefore, appears to require a careful consideration of all the collateral circumstances; and very great caution should be exercised in giving any opinion involving even a consideration of its possibility, the very occurrence of the disease being productive enough of panic without that.

Treatment.—In the premonitory diarrhœa, pills containing three grains acetate of lead, and one of opium, were given. Two at first, if the case were severe; if not, one only, and repeated in three or four hours, according to urgency. This continued for a-day was generally sufficient, any remaining looseness being easily checked, by a drachm of electuary of catechu (made with sugar instead of treacle) thrice a day.

When vomiting or collapse had already occurred, the following mixture was prescribed for an adult:

℞ Tinct. op., ℥ss.; tinct. zinzib., ʒij.; aq. carui q. s. ut ft. M. ℥iij.

A table-spoonful every half hour till vomiting cease or sleep occur.

For children a similar mixture, containing only a drachm to the ounce was prescribed—a teaspoonful for the dose. One or two doses were generally sufficient to stop the vomiting, and bring about re-action. One man, a confirmed drunkard, took ʒvi. laudanum before it took effect. In him, its use was followed by severe headache; in one or two cases, when even the above mixture seemed too stimulating or irritating to the stomach, a mixture of the laudanum with plain water was used with the best effects; in cases where the collapse seemed confirmed, a dose or two was generally given by way of trial; the chief reliance was placed in the powers of Nature, aided by hot turpentine fomentations, and almost total abstinence from all ingesta, a little cold water being occasionally allowed to wash the mouth with, or more rarely an effervescing draught. This abstinence seemed, more than anything, to relieve the constant and fatiguing retching. So soon as the fluid vomiting became tinged with bile, creasote acted as a specific, and calmed the stomach at once, in doses of two drops, with a little vinegar in cinnamon water, repeated every half hour, if necessary.

After cholera had fairly set in, no treatment was used to check the diarrhœa; and, perhaps, partly to that, and partly to the omission of stimulants, was owing the fact, that only in one case was any special treatment required for re-actionary fever, and in that case its excess was due to the abuse of stimulants by the patient after her recovery from a smart attack of cholera, and cost her her life. No diuretics seemed productive of any benefit, time and mild diluents being by far the most beneficial. A case of partial anasarca coming on after cholera, and remaining some time, was removed, like a charm, by an alkaline bath.

The best mode of applying heat was found to be turpentine fomentation and hot bottles. The sheet dipped in hot water was tried, but did not answer so well, one of my patients being nearly carried off by a secondary bronchitis. Stimulants I have found to be worse than useless, positively injurious, except at the first. Opium, I conceive, acts by virtue of its narcotic power. Every case in which I could produce the physiological action of opium recovered at once. One case seemed to me to show plainly, that it was not only *post*, but also *propter*. This was a little fellow of about two years of age, who was partially collapsed. He had got about fifteen minims of laudanum, in two doses, when the vomiting ceased, and he fell asleep. All the symptoms of collapse disappeared; the pulse became full; the cheeks became rosy; the blue lips and dark circles round the eyes gradually recovered the hues of health; but, after an hour or two, he woke up, and back came the collapse. A single dose set him asleep again, and from that time he progressed steadily.

I lost, in the first epidemic, but three out of fourteen. Only two of the second were under my charge, of whom one recovered. The only other two that did recover were cured by this treatment,—a large dose of laudanum early enough. The great error is in temporizing. It is only at first that absorption takes place; after that ceases,—which varies with the severity of the epidemic,—the less done the better. All hope of *cure* is past; and the milder the remedy, the more chance of success, as interfering less with nature. Hence the great success of lime-water and milk, weak saline solutions and *homœopathy!*

ON THE SECTION OF STRICTURE BY THE PERINÆUM, WITH CASES ILLUSTRATIVE OF ITS ADVANTAGES.

By HENRY SMITH, Esq.

In the following observations which I shall have to make, I do not pretend to bring forward anything new, or to propose a remedy which has not been hitherto employed for the cure of certain forms of stricture and its complications; at the same time, it is my wish to call attention to an operation, respecting which there is at present much difference of opinion, and I may also say, great misapprehension.

I am fully aware, that the method of treating impermeable strictures of the urethra by the perineal section is resorted to by some surgeons, both in this metropolis and in the provinces; yet, from consulting the works of those who have written upon stricture, and conversing with my professional brethren, I am led to believe, that the advantages accruing from this proceeding are not generally known; that its difficulties and dangers are much over-rated; consequently, that other measures of treatment are not unfrequently resorted to, which certainly have the semblance of safety and efficacy, but are more tardy and less decisive; therefore, in such cases which really require the quick and bold interference of the surgeon, more dangerous. It must be confessed that it is much more satisfactory, and it redounds more to the credit of the surgeon, if, by the patient and skilful employment of the catheter, he can overcome and treat with success an apparently insuperable stricture, than if, by a well adapted cutting operation, he may bring about the same result; and there is little doubt that the majority of the most severe forms of stricture may be thus successfully cured; so far is this true, indeed, that one, judging hastily, would naturally express wonder on reading the various works which have been written on the subject, and seeing the ingenious instruments which have been devised by surgeons—French, English, and American—for cutting through strictures of the urethra. But that surgeon who has seen this disease on an extensive scale, and particularly in that large class of poor, neglectful, and neglected people, who are the inmates of, and the attendants upon, our large hospitals and Dispensaries, will be obliged to confess that, every now and then, he meets with instances in which his ordinary resources will fail him, and where he will be obliged to lay aside the catheter for a more formidable instrument, and call into action his greatest self-command, skill, and ingenuity.

It is true, that one of the greatest surgeons that ever adorned the Profession in this country, and who has only lately departed from amongst us, used to make a boast that he was never foiled with the catheter, in the worst stricture, and that he considered all other measures but the use of the catheter as barbarous; yet, granting this, it is no reason why the use of the catheter should always be the least dangerous, or the least barbarous mode of practice; for we know that by force an obstruction may always be overcome in some way or other with this instrument, and that it may be pushed anywhere; but the mere getting a passage through such obstruction, or into the bladder, does not necessarily constitute either a successful or safe practice. There can be no doubt that cases are constantly occurring where a surgeon may overcome an apparently insuperable obstruction by the catheter alone, and, as he thinks, with success; but, unfortunately, a *post mortem* examination will show him that it would have been better for his patient had he resorted to a different mode of proceeding, although it may have *appeared* more dangerous and cruel.

It should be recollected that Mayern, the surgeon of Henry IV. of France, finding all other means fail, forcibly perforated a stricture, on the person of his illustrious master, with complete success; nevertheless, this bold surgeon was considered worthy of censure by the Faculty of Medicine of Paris, "propter temeritatem et ignorantiam."

The operation of opening the urethra from the perinæum is applicable to various conditions of disease of that canal; but it ought not to be undertaken until all other measures have been tried which are free from the difficulties and dangers which surround this proceeding; for although these are much overrated, yet they are not to be thought lightly of, and it may be well just to take a glance at them. In the first place, let us call to mind what is the condition of the parts we have to operate upon, and how far different they are from their normal condition. Usually, it is only in those instances where no instrument can be passed into the bladder that the surgeon employs this proceeding; and what obtains here? The continuity of the canal is destroyed, a portion of the urethra is one firm mass; in fact, a mere fibro-cartilaginous degeneration; the soft parts around are completely changed in their texture, indurated and thickened from the continual irritation of the urine which has deviated from its natural course, and made other and more convenient passages for itself. In such a state of things, it is difficult to discover the continuity of the urethra; and unless the surgeon possess patience and skill, he may carry his knife anywhere but in the right direction, and serious and even fatal mischief may be produced.

This, however, is the dark side of the picture; for the beneficial results of this proceeding when properly employed are incalculable, and every surgeon who has watched half a dozen cases will admit it. As far as my own limited observations have led me to judge, there are few operations which, when judiciously put in force, give such striking relief, both temporary and permanent, as the one under notice. I have seen the timely performance of this operation snatch the patient from the most dangerous condition, when other measures have been of no use. I have also seen those who have suffered for years, and have been brought into a wretched condition from the existence of impermeable stricture and its consequences, rendered strong and happy people in a few weeks after it has been put in force; and, moreover, I have seen in more than one instance the fatal effects of neglecting this measure.

There are three forms of disease in which this operation will be found to be necessary. The first and most common is where stricture of the entire substance of a portion of the urethra exists, has existed for perhaps ten, fifteen, or twenty years; has been neglected until at last no instrument can be got through, unless by forcing; and in consequence of which, ulceration has taken place behind the diseased part, and confirmed perinæal fistulæ have been formed. In this state, the patient is brought into a wretched condition; he suffers excruciating pain whenever he attempts to pass any urine, which only comes away in a few drops by the natural passage, or perhaps entirely passes away through the false openings in the perinæum and scrotum. He is in a constant state of filth and annoyance from the dribbling of the water, and ultimately his frame becomes shattered by the continual irritation which it is sustaining night and day. This picture is not overdrawn; any one who has paid much attention to this class of disorders will recognize it.

If the patient applies in time, and even the smallest instrument can be passed, a cure may be brought about, after a shorter or longer period, without the employment of the knife, except so far as to lay open the fistulous openings; but where no instrument can be insinuated through the obstruction, the mere division of the sinuses will be of no use; the cause still remains untouched, and the patient's condition becomes daily worse, until he is glad to resort to any measure for relief. The following quotation from the celebrated Le Dran gives a much better picture of such a case than any description of my own can give. "Let us suppose now, that the urethra is become so

callous and contorted, that it is absolutely impo sible to introduce a bougie. In this case very litt urine passes through the penis, and the callositie and fistulæ are numerous. I have sometimes see the scrotum so loaded with callosities, that, togeth with the perinæum, it appeared but one lump o them intermixed with fistulous holes. The mor callosities there are, the more the passage of th urine is obstructed, and the patient, probably, wil soon die under such circumstances;" then he goe on to say, "The means of removing this disorde is by one or more operations;" after which he de scribes a case in which he operated with success.

The results of the proceeding in such a case a this are extremely gratifying, if due care be taken to secure proper attention to the after-treatment. The immediate relief is striking; in consequence o a direct opening being made; the urine come readily away, and the patient is freed, almost a once, from the miserable symptoms he has been labouring under; in a short time, his health improves, the wound gradually heals, and the urethra canal is perfectly re-established. The following case illustrates the benefit of this operation in such circumstances:—

J. L., aged 43, a native of Devonshire. Twenty-five years since he had gonorrhœa; five years after this had symptoms of stricture, which, however, he neglected for a time. Seven years ago, he applied to a surgeon, who attempted to pass a catheter, but did not succeed. Several others tried, but with the same success. Since then he has suffered from occasional attacks of retention of urine, and endeavours have been made to pass an instrument; but none could be passed until the beginning of the present year, when a small catheter was with difficulty introduced. He at this time suffered dreadfully from pain and irritation. Soon after this an abscess formed in the perinæum, which became a fistulous opening, through which all the urine escaped. His surgeon attempted to pass the catheter, but vainly. The symptoms then increased; he was unable to sleep, from the constant irritability of bladder; to use his own expression, "he was so bad as to wish himself in the grave." He had continual rigors and night-sweats; and his health was so far reduced, that he could scarcely walk. In this condition he was sent to King's College Hospital, under Mr. Fergusson, in the early part of June.

On his admission, he was found to be in an extremely weak condition, and undergoing severe suffering. A stricture was discovered at the bulb, through which it was found impossible to pass any instrument; no urine came through the natural passage, but the whole of it passed through the opening in the perinæum, which was in an inflamed and thickened condition.

The patient was placed under a proper regimen, and attempts to pass a catheter were made, but they were useless; seeing, then, the condition of the patient, Mr. Fergusson determined to cut through the stricture, and to lay open the fistulous tract freely.

The operation was performed, June 16th, in the following manner:—a catheter was passed down to the stricture, the fistula was laid open, the knife was then carried down to the urethra upon the catheter, and the stricture was divided from before backwards; the catheter was then gradually carried onwards until it reached the bladder. Considerable difficulty was experienced during the proceeding, in consequence of the length and firmness of the stricture.

The patient suffered very little uneasiness afterwards; the instrument was allowed to remain in for five or six days, and another of gum-elastic was introduced and changed from time to time, a larger one being gradually substituted. At the end of a month the incision had greatly contracted, and a full-sized instrument could be introduced. His health had much improved, and in another fortnight the urine all passed by the urethra, and he left the hospital, telling me that he should be ever grateful to Mr. Fergusson for the great relief he had obtained, and stating that his health was better than it had been for several years.

I relate this case, as it is most fresh in my memory. It is an instance of a man who had bee suffering for many years from stricture, which ha arrived to such a degree, that no instrument coul be passed, and when the patient was reduced to miserable condition; yet, by the performance o this operation, was speedily restored to a state o health such as he had not enjoyed for years. Thi was, however, not nearly so severe an instance a I have before seen, where fistula in perinæo ha existed, and where the same proceeding has been attended with great success. I could relate such cases if it were necessary to do so; but, I shall no proceed to consider the operation as applicable to another form of disease, and shall relate a case illustrative of it.

We sometimes meet with cases of stricture o long standing, and which have become impassable to any instrument, where, instead of ulceration o the urethra, and infiltration of urine occurring gradually, a more sudden and more dangerous condition obtains—no fistula, no abscesses have existed before, but the canal behind the stricture gives way; infiltration takes place, abscess forms, and the patient is placed in great danger from the constitutional symptoms. I am not here speaking of those cases, where the whole of the scrotum and inguino-lumbar regions be come involved, and where rapid disorganisation occurs; but, where the accident is more limited, and the suppuration more circumscribed; yet serious consequences will ensue, if proper treatment is not quickly applied. In such an instance, a free incision being made in the perinæum to permit the exit of urine and pus will give relief, but only for a time; for the stricture being impermeable, the urine will come away into the perinæum, and fresh inflammation and suppuration be excited within a short period. The only treatment which will be quickly and efficiently productive of relief consists in cutting through the stricture; by this means a twofold object is gained, the present mischief is relieved, and the origin of it also removed. The following case admirably illustrates this.

Joseph P—— has had gonorrhœa eight times. Twelve years ago, whilst sailing with the late Admiral D'Urville on his voyage of discovery, he first had symptoms of stricture, for which he was treated by the surgeon of the vessel. After his arrival in England he was also treated by various surgeons, but unsuccessfully. His stricture became very bad, and about a year and a half ago he was seized with retention of urine, when Mr. Fergusson saw him, and with great difficulty introduced a very small catheter. Subsequently to this he suffered much, having occasional attacks of retention, and ordinarily his water only passed in drops. In the beginning of last winter he was seized with what was thought to be fever; a few days after, however, it was discovered that he had matter in the perinæum and groins. This was let out by incisions, and the patient rallied from an almost fatal attack of irritative fever.

After this he went to his work again, and remained tolerably well for about a month, when he was again seized with a retention of urine, accompanied with great pain in the perinæum. He was brought into King's College Hospital, when a catheter was attempted to be passed, but vainly; he was relieved by the urine coming away drop by drop. On Mr. Fergusson's visit, he attempted to pass a catheter, but he was unable to do so; the patient was much depressed; he had a dry tongue and quick pulse; it was evident that there was matter in the perinæum, and that something effectual should be done in order to relieve the present condition of the patient and prevent future danger. Mr. Fergusson, therefore, cut through the perinæum and divided the stricture, which was long and tough, almost cartilaginous. The contents of an abscess were evacuated by this incision; a good sized catheter was introduced into the bladder. This took place December 31.

Jan. 2.—The presence of the catheter caused so much irritation that it was surreptitiously extracted by a patient in the next bed; it was allowed to remain out.

Jan. 8.—The patient has suffered some pain about the loins and lower part of belly, but the wound is looking well. A No. 8 catheter was introduced with some difficulty.

Jan. 11.—Wound closing, a great deal of urine comes by urethra. No. 7 catheter passed with ease, and retained 1-4th of an hour. From this date the case went on well; the catheter was every now and then passed, until a full-sized one could be introduced with ease; on the 27th the large wound had healed up, and on the 31st, exactly one month from the operation, this man was sent out cured.

I questioned this man particularly more than six months after the operation, and he tells me that he is perfectly well; that he has not had a catheter passed since he left the Hospital, and that he can make water in as good a stream, and with as little impediment, as he ever did at any time before.

This was, without exception, the most satisfactory case, as regards its ultimate termination, that I have ever witnessed, and it is a striking instance of the benefit of this operation, for, in fact, there was nothing else which could have availed him. If the surgeon had waited some days, for the purpose of endeavouring to get a catheter through, the patient would, in all probability, have died under the irritative fever, which had very nearly killed him a few weeks previously. The advocates of caustic might say, that nitrate of silver, or potassa fusa, would have been as effectual or more safe than the knife; but, I apprehend, it would have taken many applications to get through such an extensive and tough stricture as this, and the patient might equally have died in the meantime. Those who use the concealed blade may say, internal section would have been sufficed; but to that I answer, it would not have been possible to get through it at one sitting, and the presence of the matter required that a free external opening should be made.

There is yet another condition of the disease, in which this operation may bring about the very best results. It is generally recommended, and very properly too, that a cutting instrument should only be employed in those cases of stricture where there is an impossibility of passing any instrument through without force. However, this advice should be taken with some reservation; for there are certain cases every now and then to be met with where a small catheter can be introduced; but at the same time, from the circumstance of the entire calibre of a portion of the urethra being affected,—a condition of things which Cruveilhier deems incurable, conjoined with an excess of irritability of the parts, no dilatation can be effected. In such an instance, a dreadful amount of suffering is undergone by the patient, and this is by no means lessened by the useless attempts of the surgeon to dilate the stricture; the consequence is, that he gets frightened, neglects himself, and all the bad effects of his disease, one by one, ensue, chronic inflammation of the bladder, abscess, perineal fistulæ, and general constitutional disturbance, which reduces him to a pitiable state.

If the surgeon attempts to pass an instrument it cannot be borne; and, should he reach the stricture, no dilatation beyond a certain point can be effected; and the question is, what can be done to relieve the patient, and bring about a cure.

The most satisfactory and least dangerous method to pursue, is to put the patient under chloroform, open up any sinuses that may be found in the perinæum, introduce as large a catheter as will enter without force, and there leave it for several days, if it can be borne; a great amount of benefit is to be excited, the irritability will be overcome, and the stricture be materially lessened by the constant pressure of the instrument; and if great care be taken to prevent any urine from coming through the perinæum, all fistulous openings will heal up. One or two striking instances of the practicability and benefit of this mode of treatment have been under my observation very lately.

In some cases of this kind, however, it will be found, that, even if a catheter be introduced, its presence creates such an amount of irritation, that

it cannot be endured; moreover, the excessive sensitiveness of the parts whenever any attempt is made to pass an instrument, combined with the undilatability of the stricture, renders it necessary to resort to some other measure to relieve the dreadful sufferings the patient generally undergoes. The nitrate of silver, or potassa fusa may be used, in some instances, with safety and success, if the stricture is only of limited extent; if, however, the obstruction involves any considerable length of the canal, and the parts around are much indurated, cutting through it by the perinæum will be found a most effectual and permanent remedy.

The following case, well illustrating the method of treatment in this particular condition, occurred in the private practice of Mr. Fergusson, whom I assisted at the operation, and to whom I am indebted for the particulars:—

Mr. B——, an officer in the Navy, aged 50 first applied to Mr. Fergusson in October, 1848. He was then suffering from irritable stricture in the situation of the bulb and the urethra in front of it of many years' standing. Five years previously, whilst in Greece, he suffered from an attack of ague, and ever since that period he has had occasional paroxysms. Three years since he was under the late Mr. Liston, who opened an abscess in the perinæum. He suffered so much from ague, that he attributed the greater part of his condition to this circumstance. On examination, it was found that the stricture only admitted, with difficulty, a No. 2 catheter. The patient suffered excessively from irritability of the urethra, whenever it was interfered with.

After repeated attempts by dilatation, and the use of caustic as well, chloroform was had recourse to, when a somewhat larger instrument was introduced; but the irritability of the parts returned, and the patient had continual shivering fits, and his health was reduced. After giving a month's trial to the catheter, Mr. Fergusson determined to lay open the stricture by the perinæum; and he performed this operation with the concurrence of Sir John Liddle, Inspector of Hospitals, who had had the patient under his observation for some time. A month after the operation he left town; his urethra admitted a full sized instrument, and he had no return of the rigors. Several months after the proceeding, he informed Mr. Fergusson that he was as well as ever, and had no difficulty with his water.

I need not comment on this case; suffice it to say that the operation was eminently successful, after a fair trial had been given both to dilatation by the catheter, and to the caustic.

It is not my intention to enter into a discussion respecting the different merits and advantages of this operation and that of operating with the lancetted stilette. Neither is it my wish to decry this latter proceeding, which is, doubtless, of great service in those unyielding cases of stricture which are met with in the spongy portion of the canal. I have related the preceding cases merely to show with what success this operation may be resorted to when well timed, and carefully conducted.

I need not describe the particular stages of the proceeding, for I presume that all my readers, if they have had no experience of it, are sufficiently acquainted with the directions laid down in surgical works.

The after-treatment is very important, for much of the eventual success of the operation depends upon the manner in which it may be followed up. A case which may promise to do well at first, will turn out badly if great care be not taken in attending to this part of the treatment. It should be recollected, that the canal has been laid open to some extent, and that the re-formation of this canal is absolutely necessary for a perfect cure. In order to effect this, as large a catheter as can be introduced at the time of the operation is fixed in the urethra and there kept, as long as the patient can bear it. In this time the parts will have made a rapid progress towards the healing up of the divided urethra; and the fistulous tracts which may have been opened, will gradually contract. But, for a speedy accomplishment of this beneficial result, it is necessary that the instrument should not be disturbed for several days; and that as little urine as possible should escape by the perinæum. I am aware that some surgeons consider that the urethra will become too irritable to retain the catheter so long. And if they find that much pain is caused by its introduction, they will delay using it, and the consequence will be, that the canal will again contract and the operation will of necessity have to be repeated.

But, in the majority of cases, there need be no fear about retaining the catheter for five, six, or seven days; it is surprising for how long a time even the most irritable urethra can bear it, if the patient will only have the fortitude to suffer the inconvenience for the first few hours. I lately saw an instance where there were perinæal fistulæ dependent upon the most irritable condition of the urethra I almost ever witnessed. It was necessary to lay the parts freely open, and keep a catheter in the urethra; at first the patient suffered terribly, begged and implored us to take the instrument out; but this suffering ceased, and he retained it for a week with great benefit. In another case of an old gentleman with inflamed prostate gland and most irritable bladder, I introduced a catheter, and did not take it out until the sixth day, and then it caused not the slightest inconvenience. Some time ago I was in attendance with an older and more experienced surgeon, upon a case where it was necessary to open the urethra; the catheter was retained for five or six days, and the patient went on admirably; but it was considered that it was irritating him too much, and it was removed, quite contrary to my own wish. The urine no longer found a free passage, irritative fever, of the worst description, set in, and the patient, to my great regret, died before many days.

A gum-elastic catheter should always be used for the first week or two; it should be every now and then changed, until the parts have lost their irritability, and then a silver instrument may be employed until the urethra is fully dilated, and all external openings have closed up. The general health will require continual attending to, and the condition of the urine must be watched and corrected by suitable measures. It will also be necessary, in order to insure permanent and perfect success, to pass an instrument occasionally through the urethra, as there is always a tendency to contract.

In conclusion, it may be stated, that the difficulties and dangers of this operation, are not so great as they are asserted to be by some. It is true that this proceeding, like all other equally severe measures, may be followed by unsatisfactory, and even fatal results; but I can hardly understand the possibility of three or four successive cases being lost from hæmorrhage, as I have been told was the case in one of our hospitals not long ago. A well-known surgeon, during conversation with me on this subject, stated, that the hæmorrhage from this operation was fearful, and made this the cause of objection to it; but I suspect that his experience of this proceeding must be limited chiefly to something he has read of it, or something ideal he has heard from others; for, out of the many cases which have fallen under my own observation, and which I have assiduously watched, no hæmorrhage to cause the least alarm has occurred, and hardly a bad symptom has shown itself subsequent to the operation. In one instance death ensued several weeks afterwards; but here the patient, from neglect on his part, and from previous insufficient treatment, got serious disease of his bladder, from which he sank, he having obtained great temporary relief from the division of an old stricture, which had existed for many years.

13, Caroline-street, Bedford-square,
September 1, 1849.

Metropolitan Burial-grounds.—We are glad to learn, that the Churchyards of St. Ann's Blackfriars, Spafields, St. Botolph Bishopsgate, and St. Thomas, Golden-lane, are to be closed. We hope the order will be speedily extended to other cemeteries situated in populous neighbourhoods.

HOSPITAL REPORTS.

ST. VINCENT'S HOSPITAL, DUBLIN.

[From our Dublin Correspondent.]

CYSTIC TUMOUR OF RIGHT LABIUM.

Mary M'Cerum, aged 40, nine years a widow. Thirteen years ago, which was shortly after marriage, she perceived a very small tumour in this situation. For two years it gradually increased in size until it became as large as a goose's egg, and was very troublesome in walking, and even in the sitting posture. On admission, the tumour of the present size occupied the entire of the right labium, becoming narrower as it ascended towards the vagina, and passing into that cavity; it felt elastic and fluctuating throughout; it appeared to be moveable in the cellular tissue when handled; its coverings, towards the lower and depending part, were palpably thicker than elsewhere, and recalled to the recollection the sensations produced by an old hydrocele. When she coughed a distinct impulse was conveyed through the tumour, to the hand; this impulse was perceptible in every part of the tumour, as well as in the portion of the sac which extended into the vagina. The nature of this tumour was doubtful to some who examined it, and the probability of its being a hernial tumour was even suggested. Dr. O'Ferrall was, however, satisfied that this was not the case: 1st., because the inequality of the tumour consisted evidently in an inequality in the sac itself, while the fluctuation was clearly owing to a liquid of uniform consistence; 2ndly, no pressure could effect a change in the volume of the tumour, or diminish its contents; 3rdly, on passing the finger high up along the tube of the vagina, a boundary could be detected; the tumour, at this point, could be made to swell or enlarge by pressure made below, but it could not be made to proceed further into the pelvis. On these grounds, he felt convinced that the tumour contained, not intestines, but a liquid of uniform consistence. The diagnosis then lay between chronic abscess and a tumour of cystic formation. The mobility of the tumour in the cellular tissue, the absence of adhesion to the integuments, or any process indicating a tendency to point, led him to believe the tumour was a cyst originally, whatever might be the nature of its present contents.

The tumour was punctured, and half a pint of fluid drawn off. This liquid was a brownish fawn colour, turbid, and gluey in consistence. Dr. Aldridge examined a portion of it under the microscope, and found it to contain pus globules, epithelium, and oil-drops. On introducing the finger, Dr. O. Ferrall found the interior of the cyst as smooth as a serous membrane. At the upper part of the labium, and before the sac entered the vagina, there was a distinct constriction of the sac, barely large enough to allow the finger to pass; beyond this point the sac dilated again, and ascended about two inches along the vagina, where it distinctly terminated. This bilocular cyst had no lymph or flocculent coating on its internal surface. It was treated, by laying it open to the bottom by a bistoury, by the application of solid nitrate of silver to the whole lining membrane, and by dressing with lint from the bottom. At the period of this report it is filling up with granulations, and the patient appears to be doing very well, and has suffered little or no pain or inconvenience.

ANÆMIA FOLLOWING RHEUMATISM.

There have been several cases of rheumatic fever lately in the hospital. In commenting on these in the wards, Dr. O'Ferrall stated, that he was induced to believe that this disease had a tendency, in its latter stages, to produce phenomena connected with a diminution of the globules of the blood. Some modifications in the constitution of the blood, during rheumatic fever, had been already observed; it had been ascertained that, at an early period of the disease the fibrine is increased; but it would appear that, subsequently, there is, in many instances, a diminution of the colouring matter. The attention of Dr. O'Ferrall was first called to the subject by observing that, in cases with endo-

cardiac complications, after the employment of depletion and mercury, a cardiac bruit of a different character from that which originally presented itself, continued to persist, notwithstanding the steady employment of the usual means for subduing inflammatory action. By-and-bye, cases terminating fatally came under his observation, in which, although this bruit was present to the last, no morbid appearances could be detected in the heart upon *post-mortem* examination. Afterwards, he found that a râle musicale in the cervical vessels very constantly accompanied this peculiar cardiac bruit; and he was led to suspect, that after the subjection of the inflammation by bleeding and mercury, an anemic condition followed the use of these remedies, which would require a very different treatment for its subdual. He accordingly ordered chalybeates, as in an ordinary case of chlorosis, and found the cervical and cardiac bruits to disappear under the use of this remedy. As yet, he imagined the anæmia to be due to the effects of the antiphlogistic treatment employed in combating inflammation; but during the last few years he has had repeated opportunities of observing, that a râle musicale in the neck, and a bruit accompanying the first sound over the aortic valves, very frequently coincide with the decline of rheumatic fever, in cases where no active and weakening remedies have been employed; and he has been thus led to the conclusion, that the natural tendency of the disease in its advanced stages is to produce a diminution of the hæmatosin of the blood, evincing itself by its ordinary physical phenomena. This observation is one of very great practical importance, teaching us the necessity of discriminating between those cardiac sounds produced by the participation of the heart in the general rheumatic disease, and those arising from deterioration of the blood. The treatment in the two cases must obviously be of a totally different nature.

PROGRESS OF MEDICAL SCIENCE.

FRANCE.

[From our own Correspondent.]

CHOLERA.

The weekly report of the cholera continues to present the same steadiness that it has done for the last few weeks. The number of deaths in the capital for the past week amounts to about 250; but the last day or two has shown a considerable improvement. In the provinces the epidemic is making rapid progress, and there is hardly a Department in France which has not suffered, more or less, from the ravages of the disease. Medical assistance of every kind is forwarded from Paris to those localities which suffer most; but the experience gained in the "centre of science" does not seem to profit much the circumference. The mortality varies from 40 to 50 per cent.; and this has been pretty nearly the proportion everywhere since the commencement of the epidemic. The boasted progress of medicine has not produced any good fruit here. The causes you have clearly explained, in some excellent remarks in a recent leading article; and your observations are just as applicable to the "expectant" school of France as to the polypharmic humbug of English practice. In England, everybody tries everything, and, to increase the chances of a "hit," we have innumerable compounds, administered without principle or science. The sportsman increases the number of his projectiles, to increase the chances of bringing down the bird. The English practitioner seems to act on the same theory, heaping draughts upon pills, like Pelion upon Ossa, in the hope that the mass may contain the sought-for ingredient.

In France an opposite system is pursued. Convinced that medicine has little or no effect on cholera, and not compelled by his position to poison his patients with useless compounds, the French Medical man leaves nearly the whole work to Nature, and appears to have renounced all attempts at arriving at a system of treatment by any series of experiments.

The one error is, perhaps, as great as the other; yet the results are nearly the same. Dame Nature cures as many as the apothecary.

En attendant, there are some who do not despair of finding a *cure* for the malady, led away by the vulgar error, that medicine cures disease, just as an alkali saturates an acid. M. de Rennes, a Hamburgh banker, has left 100,000 francs to any one who shall attain this desirable consummation. The Academy of Medicine at Paris is constituted judge. Indeed, we have not far to go for a successful candidate, if we are to believe his assertions; but, unfortunately, no one can get at him in the dungeons of Vincennes. M. Raspail assures the world, that he can cure cholera, and in the following manner. I extract literally from his last manual:—

'To preserve yourself from an attack of cholera, you must follow the camphor and aloetic regimen; employ a nourishing diet, well seasoned with garlic, pepper, and ginger; you must employ frequent lotions with the camphorated alcohol, or with eau de cologne, and frictions with the camphor pomatum.

"Should the disease attack you, you must continue the above, and a cure will be obtained by the following treatment:—A vermifuge poultice to the abdomen, repeated every quarter of an hour, with strong frictions of the camphorated alcohol, while the poultices are being prepared. Aloes and the vegetable broth are then to be taken, and followed by the tobacco lavement or vermifuge. Every hour fifteen centigrammes of camphor in a glass of tar water; lotions of camphor water on the head, neck, back, and wrists; frictions with the camphor pomade from the neck to the anus; frequent gargling of the mouth with salt and water. When you have pursued this treatment for a few hours, take fifteen grains of crystallized calomel, and some castor oil half an hour afterwards.

"When the crisis has passed over, sedative and alkalino-ferruginous bath, with frictions on coming out. Strong aromatized nourishment as soon as your appetite returns. Salt and water for drink."

I send you the above as one of the curiosities of medical literature; yet the unhappy maniac who produced it is regarded as a martyr by the people, and many a sturdy patriot will assert to you "that Raspail could banish the cholera, if the re-actionists would permit him."

CHEMISTRY OF RESPIRATION.

MM. Regnault and Reiset have published in the last Number of the *Annales de Chimie*, a most elaborate paper on the above subject. The following are the principal conclusions at which they arrive:—Warm-blooded animals, submitted to their usual diet, always disengage a small quantity of nitrogen, varying from 2-100th to 1-100th of the oxygen consumed. When deprived of food they often absorb nitrogen in the same proportion; and this chiefly holds good with regard to birds.

When the diet of an animal is changed, or when it suffers in health from change of its ordinary diet, then it absorbs nitrogen as before.

The relation between the quantity of oxygen contained in the carbonic acid, and the total quantity of oxygen consumed, seems to depend rather on the nature of the food than the class of the animal.

The relation is nearly constant for all animals of the same species, where the diet is perfectly uniform. When the animals are kept fasting, the relation between the oxygen of the carbonic acid and the sum total of oxygen consumed, is nearly the same as when the animal is fed on flesh. The reason evidently is that, in the former case, the animal furnishes for the purposes of respiration its own flesh, which is nearly the same as the flesh eaten in the second case.

The relation between the two sums of oxygen varies for the same animal between 0·62 and 1·04, a fact which overthrows the theory of Brunner and Valentin.

The experiments of our authors also seem to prove, that though the chemical changes that take place during respiration are the cause of animal heat, they are too complex to permit of calculating the heat from the quantity of oxygen consumed, as Lavoisier has done, and as many philosophers of the present day believe.

It is not true, besides, that the excess of oxygen, which is not found in the carbonic acid, serves to convert hydrogen into water.

When the quantity of oxygen is increased in the air breathed, the results are not changed in any notable manner, and the same remark applies to cases where the nitrogen was replaced by hydrogen.

Finally, the authors demonstrate this curious fact, that some hybernating animals (the *marmotte*) increase sensibly in weight during their hybernation, from the mere effect of respiration; but the augmentation is not indefinite, for the animal urinates occasionally.

M. Regnault and his colleague propose completing their observations by a series of experiments on man. M. Valenciennes is engaged on cold-blooded animals. It would appear, however, that want of funds to purchase the necessary apparatus prevents M. Regnault from following up his design for the present, and money is too scarce in France just now, to permit any hope of his obtaining assistance from Government. The truth is, that the affairs of the country are in the hands of a set of adventurers, who think of nothing but "making their hay while the sun shines."

DEVIATION OF THE MAGNETIC NEEDLE.

The Meeting of the Academy of Science, which is ordinarily dull to a most orthodox degree, was yesterday enlivened by a happy reply from Despretz to the note of Professor Pouillet, noticed in a former letter. The subjects in dispute, if you remember, were certain electrical phenomena, which M. Despretz attributed to heat; the Professor to the action of "certain currents of air, whose existence had not been suspected before his time."

M. Despretz, in a few words, exposed the incorrectness of this assertion. Our own countryman, Cavendish, in his learned dissertation on the earth's density, described minutely these currents and their effects; nay more, he employed the very same means as Professor Pouillet for demonstrating their existence and action.

M MATTEUCCI ON THE VOLTAIC ARC.

M. Matteucci, from whom so many important observations concerning electricity have already emanated, has addressed to the Academy of Sciences a long memoir on the transport of heat and light from one extremity of the voltaic arc to the other. A brief analysis of this interesting paper may be acceptable.

The machine employed by M. Matteucci was the common electro-magnetic apparatus employed in medicine. It acts without interruption for two days, with a few elements of Bunsen or Grove, and furnishes a constant series of electric sparks, corresponding to the rapid interruptions of the circuit.

In all his experiments M. Matteucci employed two similar points of the same metal, as the extremities between which the electric spark was to be developed. As soon as the apparatus is set in action, the positive extremity becomes incandescent; on its surface are formed a number of globules of red and melted metal, which fly off, leaving small cavities behind them, and become attached to the negative extremity, where they form little balls.

On bringing the two points of iron into contact, a very beautiful and interesting phenomenon presents itself: a double cone of incandescent lava, giving out a very brilliant light from its centre, is formed with the base of each cone resting on the point of iron, and the discharge of lava continues from the positive to the negative pole.

A diffuse light envelopes the two metallic points, varying in colour with the nature of the metal used, and in every respect similar to the electric light produced by metals.

The light, or flame, is constantly traversed by bright sparks, similar to those produced by hammering hot iron, and the sparks burst outside the electric flame. Finally, a number of very brilliant and moveable sparks appear on the negative extremity. When the direction of the current is changed, this light leaps instantaneously from one pole to the other.

Our author also examines the transport of matter by means of the spark between the two metallic extremities. For this purpose, he employs a point

and a blade of similar or different metals,—making the blade occasionally positive or negative. The results were then carefully examined under the microscope.

In every case there was transport of metallic substance, from the positive to the negative side. The round spot formed on the blade, and is composed of a central part, formed of melted metal transported from the opposite pole. Round the centre we find a circle of a more or less deep colour, according to the metal used. When the blade is positive, the signs of fusion are most manifest, the stains hardly perceptible, and the circle is of a very deep colour; when the blade is negative, the contrary occurs. If a drop of gum-water or spirits of turpentine be interposed between the point and blade, then the drop is soon saturated with a black cloud of the metal in a state of extreme division, and the spot on the blade does not appear.

As to the production of light by the negative pole, M. Matteucci has found that it never occurs without the presence of a platinum point at the positive extremity; the nature of the metal at the negative pole is then a matter of indifference. On the contrary, if the negative extremity be in platinum and the positive in iron, zinc, copper, &c., the fixed light is no longer observed on the negative pole, or very confusedly. As to the cause of the phenomenon, M. Matteucci is inclined to attribute it to the heating of the positive pole, whence a number of incandescent particles are thrown off from the negative.

But it remains to determine the cause of the great inequality of heat between the two poles.

After a series of ingenious experiments, which it is unnecessary to describe here, the Author concludes, that the difference of heat depends, in part, at least, on the alteration of the surfaces,—that of the negative pole being infinitely the greatest.

In concluding his memoir, the Author expresses a hope that he has demonstrated the dependence of the phenomena of the voltaic arc on the transport of matter from the negative to the positive pole. We already know, from the experiments of Porret, that this interchange does not depend on the heat developed by the electric current.

SCOTLAND.

[From our Edinburgh Correspondent.]

We observe, in last Saturday's *Medical Times*, a notice from the Scotch Newspapers, announcing a death from chloroform in Glasgow. Were the subject one in which the interest of the public is less concerned, we would willingly let this newspaper paragraph pass unnoticed; but, as it assumes the character of a proof of the dangerous nature of chloroform, to let it pass would be a sacrifice of truth. The friends of the young man have so penned the notice as to extort a pointed reference to the unfortunate case. We have received assurances from Glasgow that the death was not an accident. The young man was found dead, with the door of the apartment locked, and nothing more is known of the quantity of chloroform inhaled, or of the purpose for which it was used, except what may be inferred from that circumstance.

It was announced in the correspondence from Scotland last Saturday, that the election of an assistant surgeon to the Edinburgh Infirmary was appointed to take place on the 1st of October, the vacancy being created by the expiration of Professor Miller's period of duty as Acting Surgeon. It is competent for the Managers to prolong the Professor's period of service on sufficient reason being shown. Mr. Miller has accordingly applied to them to exercise this privilege in his favour; and if his request be granted, there will be no vacancy. On this point, it appears, that no decision will be given till the 1st of October, the day previously fixed for the election. There are five surgeons to the Edinburgh Infirmary; one of whom, the Professor of Clinical Surgery in the University, holds a permanent appointment; and the rule as respects the remaining four is, that each should serve four years as Assistant and four years as Acting Surgeon, and that after eight years he should be honourably placed on the shelf by being appointed one of the Consulting Surgeons. When this rule is allowed to go on undisturbed—a new Assistant Surgeon being appointed every second year—it works smoothly enough. The Surgeon passes two years in each of four positions; namely, Junior Assistant Surgeon, Senior Assistant Surgeon, Junior Acting Surgeon, and Senior Acting Surgeon. But as the Senior Acting Surgeon enjoys certain advantages over the Junior Acting Surgeon in regard to the number and choice of his patients, and the privilege of giving clinical lectures, it is thought a hardship if by any accident a Surgeon completes his term of eight years without having held the position of Senior Acting Surgeon for the full period of eight years. Accordingly, Professor Miller's plea for the extension of his service is, that, though he has been nearly five years Acting Surgeon, he has been less than a year Senior Acting Surgeon. It is not improbable that the Managers will grant Mr. Miller's request to the extent of another year's service, though such a course tends very much to perplex the rule on which they profess to act in general. To obviate the charge so apt to be made against the Governors of Hospitals of doing things capriciously in defiance of their own rules, it is right intending candidates should take the pains to learn how the matter stands. In 1840 two vacancies occurred at once, and Dr. James Duncan and Mr. Miller were then appointed both at the same time, Dr. Duncan being senior. Two years after a vacancy among the Acting Surgeons occurred, and Dr. Duncan became Junior Acting Surgeon. In consequence of his serving only as Assistant Surgeon, Dr. Duncan in no more than six years from his first appointment, had completed his four years as Acting Surgeon; so that the Managers were induced to continue him as Acting Surgeon a year ago, when he completed his entire term of eight years. Thus, though Mr. Miller has been already attached to the Infirmary one year longer than Dr. Duncan, whose first appointment bears the same date; yet he has served only five years as Acting Surgeon, while Dr. Duncan served six in that capacity, having been four out of these six years Senior Surgeon.

The rule laid down by the Managers is doubtless intended to raise up a succession of young surgeons, by affording, at an early age, to those who have a turn for operating, the opportunities which are only to be met with in an hospital. Still it is not without its disadvantages, as throwing the surgeon off just at the time when his skill has reached the height to reflect credit on the Institution. The extension of Dr. Duncan's appointment as Acting Surgeon to six years, was, perhaps, nothing more than what the strict observance of the rule of the house required for the purpose of enabling him to complete his eight years in office. The particular advantages he enjoyed were rather by accident than by the favour of the Managers. And, if Mr. Miller's present request be granted, it should be expressly stated, that this course is taken not so much for the sake of putting him on an equal footing with Dr. Duncan, as for the purpose of rewarding him for the skill and ability which he has displayed as a surgeon in the Infirmary. On this ground, and not on the plea of right, we believe Dr. Duncan's re-appointment was made.

At the last election there were four candidates, namely, Dr. Richard Mackenzie, who was elected, Professor Goodsir, who we understand declines to come forward again, Dr. Burn Murdoch, and Mr. Struthers. One new candidate is already announced, if the vacancy come to be filled up, namely, Dr. Cornwall.

Edinburgh Royal Infirmary.—A meeting of the inhabitants of Kinross was held there on the 29th ult.,—David Syme, Esq., brother of Professor Syme, of Edinburgh, in the chair,—for the purpose of raising subscriptions for the Royal Infirmary of Edinburgh, the funds of which are in a depressed state. The collection which has been made in Kinross, in consequence of this meeting, already, we understand, amounts to nearly 40*l*.

TABULAR RETURN OF CHOLERA CASES.

The Table of Treatment of Cholera cases, a specimen of which we gave last week, is now ready for delivery; and any Member of the Profession may obtain the same on application at our Office. We cannot engage, however, to send more than one copy gratuitously into the country. Should more be required by any Medical Gentleman, any number may be obtained by enclosing stamps sufficient to cover the expense of postage. The Blank Form is printed to contain numerous Cases on one Sheet.

Complaints having reached us of the irregular delivery of the Medical Times *in the country by the Booksellers and Newsmen, we state, for the information of our readers, that this Journal is always published early on Friday afternoon, so that it may reach the Provinces by post on Saturday morning. Perfect regularity of delivery may be insured by ordering the* Medical Times *direct from the Office, 147, Strand. The Yearly Subscription is paid in advance.*

Correspondents are requested to address their Communications to "The Editor of the Medical Times *147, Strand."*

TO SUBSCRIBERS.

Subscribers in want of any of the back Numbers are recommended to complete their sets. Cases for binding the volumes, price 2s. each, are now ready for delivery.

New Subscribers will oblige by forwarding their Names direct to the Office, 147, Strand, or to the News Agents or Booksellers. All Post-office Orders should be made payable to the Publishers, Wm. S. Orr and Co.

THE MEDICAL TIMES.

SATURDAY, SEPTEMBER 15, 1849.

The Cholera Committee of the College of Physicians have just issued another Circular to the Fellows and Licentiates of the College respecting the terrible disease from which we are at present suffering so severely. In this letter, the Committee bring before the attention of their correspondents the chief points concerning which it is desirable that information be collected. They enumerate the several modes of treatment which have been proposed, in order that each of them may, if possible, receive a fair trial, so that "with the co-operation of the members of the College, the Committee may, it is hoped, in some cases, be able to fix the kind and amount of benefit derivable from particular remedies or plans of treatment; they may establish the superiority of some remedies, and, with regard to others, may show that their use ought to be at once abandoned." At the end of their letter the Committee propose a series of very pertinent questions, to which we desire to give as wide a circulation as possible, and have, therefore, elsewhere printed them.

We are most happy to see the College of Physicians coming forward in this way, and we can assure them that in the furtherance of the object they have in view they shall have our most strenuous support. We have always been

of opinion that no other public body would, at the present time, be able, with any effect, to call for, and elicit the experience of the Profession; and we have been equally of opinion that, without such a combined inquiry, either in this or in some other country, Cholera would still remain unarrested and incurable,—the curse of the people, and the opprobrium of the Profession.

But there are still some points to which we should be glad to call the attention of the Committee. And first we would beg them to remember, that the greatest possible accuracy on the part of their correspondents is absolutely necessary. It will not do, that a man shall deal in vague platitudes of what his experience has taught. The first question to every man should be, What is your opinion on such a point? and the second, what are the facts on which you found such opinion? If the facts are not forthcoming, though a Sydenham enunciated the opinion, it would be received with doubt. If the Committee wish really to learn the effects of treatment in Cholera, let them demand the details of the cases; let them have the opportunity of considering these cases, and of determining whether they bear out the judgment rested upon them. Now is the moment for the use of an accurate method of inquiry; if this be not used, we have great doubts whether the forthcoming Report of the Cholera Committee will not merely add another to the long list of books which are read, disputed, laid aside, and forgotten. But an accurate method may elicit information of such value, that the subject of Cholera may be more fully elucidated than any other in the whole range of medicine.

But, secondly, we would ask the Cholera Committee this question, What is it you wish to do? Is it not to come to some fixed and settled decision regarding the nature and treatment of cholera? If so, why restrict yourselves within the narrow limits of your College Lists? Are there no observers except those who have passed through the dusty portals of Pall-mall; no Physicians, who are not Licentiates, whose opinions may yet be worth the asking; no General Practitioners, whose practical knowledge may repay the seeking for? Why should not the College constitute itself the legitimate head of the Profession, as it ought to be, and demand from the whole Profession that knowledge which is literally to be a saving and a healing knowledge? Let the Cholera Committee make known their intentions throughout the limits of the Empire; nay, let them, if they can, gather their subject matter from the whole of Europe, being certain that no pains and no labour will be too great if they can unravel this intricate problem, and indicate to the nation the mode in which it may save its sons and its daughters from this fearful plague.

Thirdly, we would beg the Committee seriously to consider what they have undertaken. They have now pledged themselves to a work of no ordinary kind. When an individual member of a Profession undertakes to elucidate any special point, and fails in his attempt to do so, we attribute the failure to his incompetence, or to his want of opportunity. But when a body, like the College of Physicians, enters upon any investigation, if its conclusions are abortive or erroneous, the reputation of the whole Profession suffers in this error of its leading Corporation. It is a public confession of incapability, and, did we anticipate such a result, we would say to the College, "stay in your course, and enter not on this inquiry, which you are unable to comprehend." But that such an untoward result may not arise, that we may not witness the spectacle of the greatest Physicians of the day baffled and perplexed, we would strongly urge the College of Physicians to enlarge their basis of inquiry, to call on every labourer, not only in our Profession, but in all the collateral sciences, for his contribution, to restrict themselves to no particular set of men for their respondents, but to accept knowledge from every quarter, in the belief that all things that can add to the accuracy and extent of investigation should be sought out and used by them.

"THE EVILS OF ENGLAND."

Some months have now elapsed since the publication of a little work having for its title "The Evils of England, Social and Economical." The Author's object, as told in his preface, was, "to enter a strong and earnest protest against mendicancy under all its disguises; against charities in many of their forms; against Poor-laws in every possible or conceivable shape; and, against all kinds of waste;" and his views were set forth in about forty epigrammatic little chapters, containing many acute observations, not the less striking for the brevity with which they are enunciated. The reputation of the London Physician, to whom the authorship of this work has been very generally attributed, and the high position he holds in the sanitary movement of the day, are such as at once to secure his acquittal from the charge of hard-heartedness, which some thoughtless and short-sighted persons would be very apt to fasten on him in his anonymous character. We are not prepared to yield our assent to all his dicta; but he is evidently in earnest, and we would willingly assist him in promoting discussion on the various important questions which are opened in almost every page of his book—many of the first importance in a professional and hygienic point of view, and hence the prominent place we assign to our remarks. With this aim we propose now to make a few general observations on some of the most prominent topics, reserving to ourselves the privilege of returning to the consideration of all or any of them whenever the press of other matter is sufficiently light to allow us to do so.

Against mendicancy we protest as heartily as the most rigid political economist could wish. We should be very much inclined to vote for a revival of the old law, which awarded an equal punishment to the beggar and to the person who gave him money. But there are too many persons who, while they resist the natural inclination to drop a coin into the hand of the street-mendicant, forget to ask themselves whether this desire to relieve distress cannot be indulged in an unobjectionable manner. Let not the man who has this world's good suppose that the feeling which Nature has implanted in almost every breast, was given only to be resisted. Rather let him seek out real distress and relieve it by the best means,—that is, by enabling the sufferers to learn and labour truly to get their own bread. Except in cases of destitution occasioned by sickness, the mere gift of money is rarely beneficial. In the most deserving cases it is apt to destroy self-respect and self-reliance; and where these qualities have already disappeared, it only makes matters worse. If the rich man will not trouble himself to seek for genuine distress, let him commit a portion of his wealth to those whose duty or inclination leads them to the places where industrious Poverty sits at home and weeps,—rarely, indeed, does she lift up her voice in the streets,—and let him not be solicitous that his name should appear in the columns of a Newspaper, or in the Report of some comfortable Society. This vicarious charity is certainly not of the highest order; but it is, at least, free from evils which result from a blind scattering of sixpences and shillings among the ragged vagabonds and smooth-spoken impostors who now throng our pavements.

We agree with the Author of the little work above-mentioned, that "the patron of beggars is, unconsciously, the friend of thieves;" and we also agree, that a sound flagellation would have a very wholesome effect on both classes: but we can scarcely accept flogging as "the proper punishment for nine-tenths of all our crimes," although we certainly think that it would be less mischievous than *short* imprisonments, and that it might occasionally be found a useful adjunct to the discipline of more prolonged confinement. There are, however, many cases in which it would be more likely to confirm the offender in his course of crime than to tend towards his reformation; and, in such cases, it would be worse than useless. Our Author is careful in stating, that he recommends flogging as a *punishment* only, and that *reformation* "is a very different thing;" we take leave, however, to say, that reformation ought first to be thought of. The expenses of a prison are, indisputably, irksome; but a thief, at large, costs more than a thief in prison,—and the best economy would be to prolong the confinement until there is a fair prospect of the criminal being able to contribute to the "labour-fund," instead of diminishing it. When the term of imprisonment is sufficiently long, the prisoners may, with good management, be made to pay the cost of their incarceration; and it is not impossible that our Author's honest wish, that the thief should also earn the means of repaying what he has stolen, may also be fulfilled. If the state of mind of most of our juvenile offenders be considered, it will be evident that our present system of sentencing them to a short term of imprisonment, increasing the period of confinement on a repetition of the offence, and so going on until the wretched criminal has earned the privilege of being transported, is a wretched mockery of justice. But it would be no less so, to take such an offender and flog him, and then again turn him loose on society. How to deal with such criminals, is a question replete with difficulties. We may re-

turn to it hereafter. In the meantime, we recommend those of our readers who are in the habit of giving their spare cash to beggars, to devote it to the Ragged schools.

And here we are naturally brought to the next subject in the Preface we have quoted, viz., Charitable Institutions;—but these and the Poor-laws—on which our Author pours out all the vials of his wrath—we must reserve for future consideration.

We may mention one kind of waste which the little book does not notice. We mean, waste of good feeling. We are not disposed to sing the praises of "the times of old," and we are most desirous of looking forward with hopefulness to the advent of the "true spirit of the coming era,"—whatever these words may mean; but we see with pain many of the things which are now passing around us in this our favoured isle. There is a fondness for excitement,—an unhealthy longing for sudden wealth, —a disregard of patient industry,—a disposition to neglect our own needy brethren, and to throw away our sympathies on far-off victims of tyranny or superstition, real or imagined;—and, at the same time, our children and our youth are allowed to grow up in a state of brutal ignorance, and the civil war of class against class—the most detestable of all wars—is secretly fomented or openly encouraged. Our industrious poor have too much reason to complain, that crime is a surer passport to public favour than innocence is found to be. It is not long since the paramour of a murderer levied larger contributions on the purses of her countrymen than would have sufficed to fill the dwellings of a hundred poor families with comfort, and her only claim to public gratitude was, that having assisted her wretched partner in his crimes so long as he kept out of the clutch of the law, she was ultimately the means of securing his conviction and execution. Even the excellent Lord Ashley told with some complacency, in the House of Commons last Session, how he was retained as counsel by "a hundred and fifty of the most notorious thieves in London," and how he advised not only these, but a hundred others, as to the best mode by which they might extricate themselves from their miserable way of life. It is true, that the opinion he gave, that in the competition for employment "it was unlikely that a person of tainted character would be preferred to three persons of untainted character" was not flattering to his clients; but did he think that the probability ought to have been the other way? If not, why publish the fact of his having been among the thieves at all? There is scarcely any agent of good which is not noiseless in its operation. Let each man quietly and determinedly labour in his own sphere, in the conscientious discharge of the duties which his station in life imposes on him, or, if he will not do so, let him bear the consequences of his own default. The shameful imputation, that the idle and profligate are better cared for than the industrious and innocent must then speedily cease from among us: the immunity which we have enjoyed amidst the crash of broken thrones and ruined dynasties will be strengthened, and the tongue of the revolutionary agitation will be silent in our land.

DR. JAMES ARNOTT'S TREATMENT OF CHOLERA BY INTENSE COLD.

Among the multifarious remedies suggested in the Medical Journals against Cholera, there is none that has surprised us so much as the proposal to swallow a frigorific mixture to reduce the temperature of the stomach to that of the zero of Fahrenheit. The hair positively bristles on our heads, like so many icicles, at the bare mention of such an idea. We remember the horror which ran through the public mind when the newspapers gave an account, some years ago, of a pedlar having caused several country people to lose their fingers, by advising them, in jest, to keep their hands for some minutes in a mixture of snow and salt to cure warts, or some such trifling inconvenience. The story may be apocryphal, but it sounds like truth. Unquestionably, the common rule of therapeutics has hitherto been, that nothing colder than melting ice or iced water should be applied to living parts. Our Medical works abound in cases of sloughing from the incautious, continued application of snow or pounded ice as a refrigerant to external parts; for example, to the scrotum;—and many of our most recent authorities on the use of cold think it necessary to remind us that snow or pounded ice, owing to the caloric absorbed in liquefaction, is a much more active refrigerant than iced water. Within moderate limits the internal use of ice is, probably, more universally safe than its external application, and the swallowing of ice, and also the enema of iced water are well-established and most beneficial remedies. But, here again we are met by a host of facts, showing that even cold spring water as well as ices in warm weather, particularly when the system is exhausted by fatigue, have often proved either almost instantly fatal, or have caused a fatal gastritis. How, then, on the face of such evidence, are we to believe, that in a disease so exhausting as Cholera, it is either safe or remedial to pour a frigorific mixture into the stomach so as to bring down its temperature to the zero of Fahrenheit, or even to ten or fifteen degrees below the freezing point of water? We have a great respect for the name of Arnott; and we believe the gentleman who makes this proposal is a near relative of the distinguished author of the "Elements of General and Medical Physics;" but even this name fails to carry sufficient weight with it in this matter. There can be little difference of opinion as to the necessity of warning our more sanguine brethren against rashly following Dr. Arnott's recommendation. It is at variance, *primâ facie*, with every received principle of physiology in regard to the relations of temperature to life. It is a proposal wholly new to the practice of medicine, at least from parties of any consideration in the Profession. We profess to believe anything on sufficient evidence—we have no unalterable opinions, unless those truths are called opinions which rest on intuitive proof. But when things are brought forward, in the character of facts, which contradict all our past experience, and all our received views in relation to living action, we require something more than common evidence, before we yield our assent. We must be satisfied, not only of the veracity and good faith of the witness, but that he is not *captus oculis*, and that he has not recently ceased to be *compos mentis;* and, moreover, that he has not only forsworn in intent, but that he practically and habitually abstains from the worship of those idols which, as Bacon shows, so often stand between men and the perception of truth. If our witness come through this ordeal we will believe what he affirms, and, instead of blaming us for our doubts, he will supply us with the means of judging what kind of witness he is, and commend us for being no more sceptical than the occasion demands.

THE OPERATIVE SURGERY OF JOHANN FRIEDRICH DIEFFENBACH.

Edited by

J. STEVENSON BUSHNAN, M.D.,
Fellow of the College of Physicians of Edinburgh;

And

ALEXANDER URE, Esq.,
Fellow of the College of Surgeons of England, and Surgeon to the Westminster General Dispensary, &c.

(Continued from page 206.)

CHAPTER VIII.
TRANSFUSION.

Transfusio—Transfusio sanguinis—Cura Medeana—Methæmochymia—Transplantatio medica nova.

Transfusion is the operation of transferring blood from one individual into the vascular system of another. It was first practised by me in the case of a man labouring under hydrophobia. He had burning thirst, great intolerance of water and of shining objects, the very sight of which produced the most violent spasms of the muscles of the throat and neck. The symptoms became progressively worse, in spite of the best-directed treatment. Venesection was performed in the arm, and three cupfuls of blood were transfused from the vein of a bystander to replace what had been abstracted. The condition of the patient was at first bettered; ere long, however, the most alarming fits returned. The next day, in consequence of the persistence of the symptoms, the operation was repeated, after which he could drink water without reluctance; an hour later, unfortunately, a severe paroxysm supervened, during which he died. On cadaveric inspection, nothing unusual could be perceived; no traces either of the hydrophobia, or of the transfusion. In some instances of cholera in which transfusion was tried, the patients were icy cold, blue, without pulse, and seemingly near death. It was resorted to in the belief that fresh, warm human blood might, perhaps, arouse the paralyzed action of the heart and its vessels, in conjunction with the exhibition of other stimulants. From the first cholera patient devoid of pulse, two ounces of thick black blood were drawn with great difficulty from an opening in the median vein, by the aid of chafing or rubbing the forearm with the hand; and immediately afterwards five ounces of fresh-drawn blood injected at three successive intervals. A few minutes after the first injection, slight clonic spasms came on. Six minutes later, on the second injection being made, a deeper breath was taken, the previously dilated pupils contracted, and the eyes acquired more lustre. After the third injection, the pulse was felt faintly vibratory; the axillary artery which beforehand was motionless, afforded regular pulsations, with a rhythm of from 55 to 58 beats in a minute.

In the course of half an hour the last agony commenced as is wont in cholera patients, nowise altered in character through the act of transfusion; cadaveric examination revealed the blood coagulated in the heart and great vascular trunks. In a woman, aged sixty-five years, assailed with cholera asphyxia, whose veins were empty, and whose opened brachial artery was bloodless, fresh human blood was transfused at two intervals and within twenty minutes. At first merely alternate dilatation

and contraction of the pupil could be perceived; next a return of pulse in the brachial, and, subsequently, in the radial artery. After the second injection, from fifty-five to sixty beats could be told in the minute, and, ere long, pulsation could be detected as far as the elbow of the left arm. In five or six minutes these equable pulsations ceased, and here and there, in some of the large arteries, solitary beats were alone observable. Two hours having elapsed, the patient died without any cramps. After death, dark grumous blood and gory fibrinous clots were found in the heart and principal vessels; in the pericardium some serous fluid, but no evidence of transfusion having been performed. In the third case, of a patient, aged sixty-one years, blue, and without pulse, suffering from dread of suffocation, I opened several vessels, but obtained no blood. I then incised the axillary artery; it was perfectly empty, and on both sides you could look into the open gap. From the axillary vein I then procured, by dint of rubbing, a few drachms of thick black blood. After the first injection into the median vein of blood directly drawn from an individual, alternate dilatation and contraction of the pupil were observed, as also a faint vibration in the radial artery. No change followed the second injection; but, after the third, the pulse was stronger in the right than in the left radial artery. About three ounces of blood in all had been introduced. The pulse presently ceased, and death ensued amid the usual phenomena. The pathological appearances were the same as in the preceding case.

As far as the operation was concerned, little more could have been expected, considering that the disease was in that advanced stage in which the blood was already coagulated in its vessels. On the other hand, it might possibly be resorted to with some prospect of advantage in cases of a less desperate character.

The importance of transfusion is to be estimated rather in a physiological than in a pathological point of view. When employed as a means of resuscitation in moribund subjects it proved of no avail; in healthy persons, afflicted with insanity, it wrought no change.

The results of numerous trials, instituted by me, differed from those of most other experimentalists, although coinciding, in many respects, with those of Prevost and Dumas. The following points merit attention:—

Mammals, exhausted by bleeding, could be directly restored by transfusion of the blood of another animal of the same class, provided the operation were executed in a skilful manner, and neither air nor clots allowed to enter. Arterial blood restored suspended animation rather sooner than venous blood. In no instance did the animal ail after the introduction of either kind of blood, especially when less was transfused than had been withdrawn. When, again, a surplus quantity was injected, the animal seemed inactive and uneasy during the operation, and occasionally voided urine and fæces.

The phenomena were the same after the immediate as after the mediate transfusion by means of a syringe. Blood exposed during several hours to the air, of which the fibrin was removed, or kept liquid with caustic soda, was equally efficient with blood recently drawn.

The usual appearances, during the procedure, were alternate dilatation and contraction of the pupils, then hurried breathing; the pulsations of the heart and arteries were at first slower, eventually quicker, than natural. Alvine discharge frequently occurred; rarely, bloody urine. In the case of disorder, even of a dangerous character, following the operation, health was speedily re-established with an attack of muco-sanguinolent diarrhœa, where either too much blood, or else blood of a different animal had been transfused.

The latter produced, likewise, a quickening effect, but the animal suffered always afterwards. Giddiness, troubled respiration, palpitation of the heart, beating at the sides, intermittent pulse, at first diminished, then augmented temperature of the body, pale, sometimes dotted tongue, swelling of the belly, and death were noticed. On cadaveric inspection, dropsical effusions were discovered upon all the serous membranes, flabbiness and paleness of the heart, and dark spotty coloration of the lungs.

Graminivorous animals were less affected with the blood of carnivorous animals than inversely. Dogs mostly perished when resuscitated with sheep's or other blood. A very little strange blood made them ill. Hæmaturia followed only artificial plethora; namely, when more blood had been introduced than withdrawn. Among the mammals, cats were by far the most susceptible to strange blood, and died from a few drachms with manifest torture. Young suckling animals, which are generally little sensible to injury, were killed with a few scruples of other blood. A whole litter of kittens died in this way through dropsical effusion of all the serous membranes.

Transfusion influences the innermost vital processes, and is for this reason very hazardous. A single ounce of bird's blood injected into a large sized mammal proves fatal; and a bird itself, as for example, a pigeon, is destroyed with a few drops of mammal's blood, amid the phenomena of poisoning with hydrocyanic acid, so soon as it gets into the circulation.

The blood drawn from animals poisoned by narcotic substances introduced into the stomach produces no peculiar effect. It rarely happened that diseases, such as those of an impetiginous nature, were communicated to healthy animals by sanguineous transfusion.

It would be out of place to enter into further details; but I would refer the reader to the writings of Burdach, Mueller, and Magendie, where the most recent information on this subject will be obtained. As a therapeutic measure, transfusion is to be recommended in hæmorrhage, as enjoined by Schœnbein and Marcinkowsky. It is also deserving of trial in the instance of apparent death, as suggested by Blasius; but, of course, only *mediate* transfusion. The *immediate*, which can only take place from an artery into a vein, ought never to be attempted in the human subject.

Mediate transfusion is to be performed precisely in the manner described under the head of infusion in the preceding chapter. The vein is to be exposed by an incision through the skin, the cellular texture removed, a couple of threads placed loosely round the vessel which is to be opened between them, a canula inserted, and the blood, as it flows from the arm of another person, received into a warm vessel, taken up with a warm syringe, and slowly injected. After one or two ounces of blood have been thus transferred, the operator must pause. The total amount should not exceed six ounces.

The English surgeons, after Dr. Blundell's example, employ the stomach-pump of Reed; but this offers no advantage over an ordinary syringe.

During the operation special precautions are requisite to prevent the entrance of air into the vein. Accordingly, before the short nozzle of the syringe is introduced into the canula within the vein, a little of the blood ought to be squirted out, and the contents of the syringe only partially discharged, lest a clot be transmitted.

After it is finished, the threads surrounding the vein are to be withdrawn, the arm laved with tepid water, then dried, and the edges of the wound kept together with adhesive strips, surmounted by a compress and roller.

REVIEWS.

First Principles of Medicine. By ARCHIBALD BILLING, M.D., A.M., F.R.S., &c. &c. The Fifth Edition. Revised and Improved. London: S. Highley, 32, Fleet-street; Maclachlan and Stewart, Edinburgh; Fannin and Co., Dublin. 1849.

Since the days of Cullen, we have made considerable progress in what may be called rational medicine. We apply the term Rational Medicine to the system or method of investigating disease in use at the present day, and which differs essentially from the plan followed by the older physicians.

We are not content with a mere acquaintance with the history of a disease, and the remedies that have been recommended for it; we carry our inquiries much further; we try to discover in what the departure from the healthy standard consists,—whether we have to deal with organic changes or functional derangement, and, in applying our remedies, we seek to explain the manner in which they act, and why they are useful; so that, in undertaking the duties of a physician, we require to be well grounded in, and thoroughly understand, what Dr. Billing very properly calls, "The First Principles of Medicine."

We are indebted to a want, experienced by the Author himself, for one of the most useful medical works that it has ever fallen to our lot to peruse,—a work which has been spoken of in the most flattering terms, and which, we may add, has not received greater praise than it justly deserves.

No one who, like Dr. Billing, has felt the want of a correct system on which to base his practice, will undervalue the great service he has rendered to the Profession, in publishing these principles, which, to the young practitioner, must prove, indeed already have often proved, of inestimable value, and which will enable the more advanced practitioner to understand many things that were before unintelligible, and by the aid of which the reasoning physician will often be able to comprehend and grasp ideas that flashed upon his mind, but which, like the visions of the night, were indistinct and transitory.

Dr. Billing commences his work by stating certain admitted physiological facts; or, where he differs with the generally received opinions, he explains his own views; on this basis he then proceeds to show the true nature of pathological changes and the action of remedies, and discusses the nature of inflammation, fevers, &c. &c. He does not enter at any length on the consideration of special diseases, as he merely proposes to treat of the principles of medicine; but we may say that, whoever thoroughly masters these principles, will have learned no small part of what pertains to the practice of medicine as taught in the more systematic works on the subject.

"Many persons of great experience practice moderately well, empirically, without much brains or reasoning; but he who begins upon principle, and then profits by experience, must become a much more skilful Practitioner."

Our Author's views on many physiological and practical points are so well and clearly expressed, that, instead of altering or compressing his words, we will, so far as our limits allow, prefer making such extracts as we think sufficient to explain his meaning, necessarily, however, omitting much that is interesting; for, were we to insert all that we thought valuable, we would transfer the entire work to our pages.

"Arteries are endowed with the power of contracting on their contents so as to continue full when a considerable quantity of blood has been lost, either by hæmorrhage or artificial means." "The contraction of the heart is *muscular*; of the arteries, *elastic*. The heart contracts and *relaxes* alternately. The arteries keep up a constant *contractile pressure* on their contents; not as has been commonly supposed, an alternate contraction and relaxation, but a continued contractile effort, both longitudinally and transversely, which is overcome by the action of the heart:" "owing to this contractibility the arteries are always full. The elastic contractile force of the arteries is merely to regulate the motion of the blood, whereas the propelling power is the contractile force of the heart."

"The nerves are whitish threads, which are distributed to every part of the frame, however minute;" "they impart sensation, and direct action, and supply to *all parts nervous influence*, which excites *action*." "A variety of circumstances lead us to the conclusion, that the nervous influence is analogous to, or depending upon, if not identical with, the electric principle or fluid, whatever that be."

"Heat is extricated all over the frame; in the capillaries, by the action of the nerves during the

change of the blood from scarlet arterial to purple venous; and also, while it is changing in the lungs from purple to scarlet," "there is a perpetual system of deposit and decomposition carried on by the capillary system; carbon is continually disengaged, which mixes with the blood." "This decomposition being effected by the agency of the nerves, produces constant extrication of caloric. Again, in the lungs that carbon is thrown off and united with oxygen, during which caloric is agree set free." Animal heat is thus kept up, "evaporation of perspiration keeps the surface cool; but, in inflammatory fevers, where this is *deficient*, the body gets too *hot*; and, in low fevers, when the nervous influence is not sufficient to keep up the full fire, the surface gets cooler than the natural standard. This is peculiarly evident in the beginning of eruptive fevers, as scarlatina, where there are strong heats, with the arterial colour of the skin; but, if the same becomes malignant and low, with deficient arterialization, the temperature sinks, and the diminution of charcoal combustion in the lungs is evinced by the dusky colour of the skin, showing that the carbon is not thrown off as it ought to be; and the same phenomenon takes place in typhoid cases, and still more so in malignant cholera."

"Nervous energy is indispensable for the carrying on of the system, as this power becomes deficient, remedies that produce a vital action, so to speak, lose their power and merely act as on dead matter; thus, a blister will often not act before the approach of death, and hot water merely acts as on dead matter; it may separate the cuticle, though it cannot raise a blister."

We quite agree with Dr. Billing, when he speaks of inflammation as being a decrease of arterial action, instead of an increase, as some think. "In inflamed parts the capillary arteries are weaker in their action; there is diminished arterial action, for the action of arteries is contraction. Now the arteries in inflamed parts are evidently larger than before,—less contracted, that is, acting less." The arteries give way, and are dilated by the injecting force of the heart. "The way to diminish the inflammation is, by increasing the action of the arteries, as by cold or astringents, which make the arteries contract, that is, increase their action." "The increased throbbing of the arteries shows that they yield more to the heart's action."

"An inflamed part, when cut, will bleed freely, owing to its containing an increased quantity of blood, the arteries being dilated."

"The difference between congestion and inflammation is, that in congestion there is merely distension of the vessels; in inflammation, there is, in addition, alteration of tissue,—actual deterioration, more or less, of the structure of the capillaries." Congestion may be caused by obstruction, which may continue a long time, and be speedily relieved by removal of the cause; "but the case is different with inflammation,—the fault commences in the tissues. As soon as a want of that harmony between the nerves and capillaries which is necessary to organisation takes place, their fine tissue begins to decompose, the particles which were held together by this inscrutable agency begin to be precipitated from one another; and this takes place in every shade and degree, from the slightest scorch of the fire, or blush from the wound of an insect, to mortification and putrefaction."

Dr. Billing is of opinion, that the progress of inflammation shows the dependence of the capillaries on the nerves; the pain precedes the redness. "The action of cantharides in producing inflammation is another proof that inflammation begins in the nerve; for cantharides have no effect on the tissue of the capillaries, do not corrode or act in any way on their substance after death, when the nerves have no influence; whereas any really corrosive agent would act even more on the dead than on the living capillaries." As nervous influence becomes diminished, the capillaries relax. Now, certain agents applied to wounds cause the capillaries to contract; they stimulate them to action. "But the same agents, applied too strong, exhaust the nervous influence, and relaxation (which has been erroneously called arterial action) takes place." There is evidently much truth in Dr. Billing's views connected with inflammation; but we think there is a want of sufficient data to justify his conclusions altogether. Perhaps these data may be supplied by discoveries made by the microscope; but, for the present, we do not give our entire assent to his views. We know, that in inflammation there is an increased afflux of blood to the part; independent of the dilated state of the capillaries which retains the blood; the circulation is more rapid towards and around the congested parts, as observed in the first stage of inflammation, which is active congestion. Now, Dr. Billing objects to the use of the expression determination of blood, as applied in a case like the present, and says, that the heart has no power to determine an increased flow of blood to any particular part, and to illustrate this, says, "When the water is sent through the main pipe of one of the waterworks, it cannot be determined to any house in particular, but whichever house has the largest cistern will receive most water. By this I wish merely to illustrate, that what is called determination is not active, but passive." Now here we encounter a difficulty, —how to account for the quickened circulation in the part. Perhaps, on irritating any particular spot, so as to produce congestion, followed by inflammation, the heart may at once sympathise, and act with greater vigour, so that, not merely in the inflamed part or its neighbourhood, but throughout the whole system, the circulation is quickened.

"Secretions are carried on by fine capillaries, which, by their great number and extreme minuteness, envelope, in the form of a vascular membrane, the ultimate or terminal ramifications of the excretory ducts of all glandular organs." "These capillaries are many times smaller than the cryptæ, follicles, tubuli seminiferi, tubuli uriniferi, &c., as they are called in different organs, and do not communicate with them by open or terminal extremities, as Ruysch and later anatomists have supposed; on the contrary, the finest capillaries are seen to join one another, so as to form again larger and larger trunks, then called veins. Secretions, therefore, are vital transudations from the capillaries into the excretory ducts of glands." "It does not follow, that where there is diminished secretion there is obstruction. On the contrary, there may be more space for the flow, but then in a slower stream." "Hence, to account for the diminished secretion, it is not necessary to suppose either any 'spasm' or '*error loci* of the red particles getting into the colourless capillaries:' it is enough to consider, that the fluids find an easier way, by the enlarged capillaries onwards into the veins, than into the ramifications or cœca of the excretory tubes, unfitted as the capillaries are for secretion, owing to the morbid alteration of their physical condition; and besides, and yet more particularly, through the alteration of their dynamic (galvanic or electrical) condition, consequent upon the alteration of the supply of nervous energy to the part, the original cause of all the disturbance. Local enlargement of the capillaries explains that kind of diminished secretion where the heart is not deficient in injecting power; the relaxation of the capillaries, from want of nervous energy, producing a deficiency in the current of the blood; as in a dry skin when inflamed or feverish, or kidneys inflamed, or their capillaries enlarged by cantharides, so as to diminish secretion, in the manner first explained."

"In some cases of disease, when the secretions of the skin and kidneys are deficient, we renew them by bleeding, digitalis, antimony, &c., which lower the force of the pulse, thereby diminishing the distension of the capillaries, in conformity with the above statement. On the other hand, in health, stimulants, such as diluted fermented liquors, by increasing the nervous energy in the kidneys, &c., and quickening the circulation, at the same time increase secretion; or medicines, such as *uva ursi*, digitalis, antimony, neutral salts, &c., have a local astringent effect when circulated, besides their influence on the pulse. Stimulants cannot increase secretion by quickening the circulation when the capillaries are in a state of debility and morbid congestion; and a still further proof that they are in a state of morbid congestion, is the effect of cold to the loins in such cases in renewing the secretion; and the constringing effect of cold water, even cool air, in promoting the secretion of insensible perspiration, and thereby softening the congested skin in scarlatina."

In speaking of certain diseased states, Dr. Billing objects to the use of the word "irritation," and prefers calling that peculiar condition "morbid sensibility." There is no doubt, that the word irritation is frequently used in an equivocal sense; and even though we perfectly understand what is implied, still it is certainly less confusing to beginners to give words their common meaning. We may refer to his explanation of the use of nitrate of silver as an application to ulcers, to show where he would use the expression "morbid sensibility." When nitrate of silver is applied to an ulcer, it causes smarting at first; the pain, however, soon subsides, "so that a patient will fall asleep shortly after the application of nitrate of silver to an ulcer which had banished rest for several days and nights by its morbid sensibility. The beneficial effect may be thus explained:—The nerves of the part having become inflamed, and their vessels partaking of the debility of those in the surrounding tissues, the astringent diminishes the inflammation in the nerves, and thus removes their morbid sensibility, bringing them to the state of nerves in a healthy granulating part, in which those below the granulations are sensitive, but not more so than natural. Oil of turpentine applied to a burn acts on the same principle of bringing the nerves to the state of those in a healthy part, not merely by astringency, but also by eliciting more nervous influence in a part whose vital power is depressed."

"Morbid sensibility arises either locally, or in the nervous centres, in consequence of the lesion of the nerve being communicated to them, whether the lesion be in the sensitive or organic filaments: in the latter case there can be no evidence of morbid sensibility until the lesion is propagated to the nervous centre; as in tetanus arising after a cut has healed almost by the first intention, without pain in the cicatrix; or convulsions from worms in the intestines which have caused no pain."

Dr. Billing arranges medicines under the heads of *stimulants*, *sedatives*, *narcotics*, and *tonics*. He denies the existence of such a thing as a specific. We greatly regret that our space compels us to pass over much that we would gladly refer to; his mode of accounting for the action of different medicines will be found full of interest. We may just quote one or two passages that will serve to convey an idea of his views:—"Substances applied to the primæ viæ, or skin, are absorbed, and carried into the circulation; and we judge that, in this way, these metallic salts, oxydes, &c., are carried to the capillaries of diseased parts, so as to act as astringents, and strengthen and cure. We know, too, that they are adapted to different cases. Antimony, which produces sickness and lowers the pulse, *besides its local effect on the capillaries, when it reaches them through the circulation*, is suited to, and resorted to in acute diseases, such as inflammatory fevers, whether idiopathic or from injuries. Thus we can account for the efficacy of antimony in such a case as scarlatina, by its diminishing inflammation in the superficial capillaries of the skin, fauces, &c., which have been relaxed by the morbid poison, and, at the same time, by reducing the power of the circulation when it is too strong, if administered so as to produce slight sickness or nausea; or, if there be a low state of fever not requiring reduction of the pulse, the antimony may be given in small repeated doses, so as to circulate to the capillaries without depressing the pulse. Mercury, which has not this nauseating property, acts less on the pulse than antimony, but, perhaps, even more upon the capillaries when circulated to them; hence it is oftener used in chronic cases, both syphilitic and others."

"Mercury and iodine remove morbid growths by starving them, which they effect by contracting the capillaries, and not by increasing absorption, as is a commonly received opinion." Spongy gums and swelling of the fauces, arise as secondary causes.

Mercury at first causes contraction, but its continued use leads to a loss of power from over-action, —there is relaxation,—the power of contraction is lost. Though there is much that seems to bear out Dr. Billing's opinion, that there is no such thing as a specific, we are still not altogether satisfied with his arguments. We know that we may administer the same class of remedies in certain diseases without producing any effect until we at last resort to the one that experience has proved will cause the disease to yield rapidly. We have been struck on reading the homœopathic arguments in fauour of their doctrine, that medicines known as specifics afforded the strongest evidence in favour of the law "Similia similibus curentur;" and were they to stop short with this, and not proceed to infinitesimals, contenting themselves with asserting that they had discovered the law of specifics, we would not be so much surprised at men of character and reputation taking up their ideas. In regard to the action of antimony, we believe it is very generally prescribed as a nauseant, with a view to cause a general depression, and lowering of the heart's action. It is well to bear in mind, that being carried in the circulation to the remote capillaries, we may, with Dr. Billing, suppose that on them it exerts a beneficial constringent effect. Taking into account this double action of antimony, we see why it is, that in cases of acute inflammation we may follow up the good effects produced by bleeding, by administering nauseant doses of tartar emetic.

Passing by Dr. Billing's opinion that fever is dependent on a diminution of the nervous power, we proceed to the treatment of fever, which is ably discussed, and the rules laid down for abstraction of blood of great practical value. If there is anything in them which we are disposed to object to, it is, that we think our Author is rather too great an advocate for bleeding, and that rather too much is said against the use of stimulants. We believe that no one will ever have to treat fever except at the bedside, and though we may object to Dr. Billing's condemning the use of stimulants, we question if this does not arise from his having witnessed the bad effects of stimulants when injudiciously administered, rather than from any want of confidence in remedies which, when properly used, will often sustain a person through fever when all other treatment is valueless. What the Physician has to learn is, when to deplete, and when to stimulate; this cannot be learned except by observation at the bedside. Cases arise where it is absolutely necessary to abstract blood, from the arm or with leeches; but we believe, as a general rule, the less blood that can be taken the better, ever bearing in mind that fever has a certain course to run, and that if the patient can be supported for the required time, and local affections that arise during its progress be kept in subjection, recovery may be fairly anticipated. Now it often happens, that when a patient is bled at the onset of fever, the system receives a shock from which it never rallies. Again, how many cases of fever are there that early call for the administration of stimulants. "As a general rule," says Dr. Elliotson, "in the fevers that I see in London, venesection is not demanded in one case out of thirty or forty." We make these remarks, because we think that Dr. Billing advocates the one system and condemns the other, more than we are disposed altogether to agree with, at the same time that we think the utmost care is requisite in the use of stimulants, and are sure that his observations on bleeding will never mislead, but, on the contrary, will prove most useful to the judicious, observant practitioner, who will know how to apply them; but the inexperienced may be disposed to take up the practice with too great zeal.

Most of our readers are probably familiar with Dr. Billing's opinion of cholera,—that it is a fever; and, we think, whoever studies the disease will be disposed to admit the strength of his argument, even if they do not yield full assent to it. Dr. Alison, who is one of the most accurate observers of disease that we know, says, "There is a form of fever, of rare occurrence, but of great pathological importance, which has lately been described under the title of congestive; and, although that term expresses what is probably a concomitant, rather than the cause of the peculiarity of the symptoms, yet it is, perhaps, better to endeavour to fix its meaning than to substitute another.

"In this variety of fever the symptoms of the earliest, or cold stage, assume their highest degree of intensity; and feebleness of pulse, coldness of surface, muscular debility, and depression of all the functions of the nervous system, approaching and sometimes amounting to complete coma, are the leading symptoms. Spasms attend some cases of this kind, and vomiting attends others. Such cases occur now and then in epidemics of common continued fever; but are more frequent in the most malignant epidemic diseases, plague, yellow fever, cynanche maligna; and many cases of epidemic cholera are closely analogous to them. In all these cases, if this first and very dangerous effect of the remote cause of the disease is recovered from, it is usually succeeded by a distinct, but generally feeble, febrile re-action."

We refer to Dr. Alison, to show that the evident connexion between fever and cholera excited his attention, and the extract we take from his valuable work on "Pathology and Practice of Medicine," is as strong evidence as Dr. Billing need adduce to strengthen his own opinion.

The treatment, Dr. Billing says, should be that of fever: his prescription is—

'Water, half a pint; tartar emetic, two grains; sulphate of magnesia, half an ounce; mixed.

"The dose is, for an adult, (from 15 years upwards,) a table-spoonful every half hour; for a child of a year and a half or two years, a teaspoonful; and for the intermediate years, a proportionate dose."

There are many subjects we would have gladly alluded to, but we have already extended this review to a considerable length.

We must, however, notice Dr. Billing's theory of the cause of the sounds of the heart. We can but make our readers acquainted with it by quoting the following from his advertisement to the second edition:—"In an Essay read at the anniversary meeting of the Hunterian Society, (Feb. 9, 1832, and reported in the *Lancet*, May 19, 1832,) I first stated publicly, 'that the push or beat felt at the side is caused by the ventricular muscles in their systole to expel the blood. The first sound is caused by the tension produced in the shutting of the auriculo-ventricular valves, and the second sound is caused by the tension produced in the shutting of the ventriculo-arterial valves,' " &c., &c. Again, in 1840, Dr. Billing published some further remarks to support his view of the sounds being caused by valvular tension; and to prove that the supposition, of the muscular action of the heart having anything to do with causing the first sound, is erroneous. In arguing against Dr. Hope's opinion, he says, "Now, I contend that the first sound, as well as the second, is entirely valvular, and deny that any part depends upon muscular noise (*bruit musculaire*); for when there is simple hypertrophy (increase of muscle and muscular action), there is diminution of sound, although more of the condition necessary to *bruit musculaire*. This contradicts his opinion, and confirms mine, inasmuch as it is the valves being encroached upon, and their having less blood to stretch them, which prevents their producing the usual sound." Our readers are, of course, aware, that physiologists are pretty generally agreed, that the second sound is caused by the sudden tightening of the semilunar valves; but the cause of the first sound seems to be still an unsettled question. The most recent writers on physiology still hold the opinion, that the sound is in a great measure muscular, but may, in part, be attributed to the sudden tightening of the auriculo-ventricular valves, and when on the stretch "they may vibrate, like sounding boards, with the vibrations communicated to them through the tense tendinous cords that attach them to the vibrating and sounding muscles."—(Kirkes, p. 89.) Dr. Billing's is certainly the more simple explanation, and we are disposed to consider it the true one; and we think Valentine's experiment, referred to by Kirkes, is strong evidence in support of it. "If a portion of a horse's intestine, tied at one end, be moderately filled with water without any admixture of air, and have a syringe containing water fitted to the other end, the first sound of the heart is exactly imitated by forcing in more water, and thus suddenly rendering the walls of the intestine more tense."

We now conclude our notice of this very instructive and practical work, and would strongly advise our readers not to rest content with what we have said about it, but to get the book for themselves and study it carefully; and, when they have done this, we have little doubt that their opinion will agree with ours, that every page abounds with useful matter, and that the Author is a pleasing writer, as well as an accomplished Physician.

THE NITRATE OF SILVER IN CHOLERA.

[To the Editor of the Medical Times.]

SIR,—There was a reference in one of your late Numbers, to my employment of the nitrate of silver in the treatment of cholera. It is now my desire to place before the Profession a few facts, exhibiting the results of this practice. This must be done briefly, if I can, if not, at such length as the case requires. I will, at a future time, record more at length my personal experience of the present epidemic.

Not many men, it will be conceded, have engaged in the treatment of this disease with a fuller knowledge of its literature; and few have had ampler opportunities of testing the principles laid down by theory in the field of practice. I began my operations against this epidemy by the employment of salines, with the fullest reliance on their efficacy; and exhibited chiefly common salt at short intervals, in the combination recommended by Dr. Stevens. I met with many difficulties in these attempts:—1st. My private patients refused to take the salt, on account of the nausea it occasioned, and perhaps, also, from the simplicity of the remedy, which they could, easily detect. 2ndly. I was compelled to defend myself before an ignorant "Coroner's Jury," against some observations that had been dropped, in reference to my employment of this agent. These difficulties constituted no valid argument against the remedy, and I, therefore, altered the composition of my mixture; and, after much trouble, devised a form which respectable persons could not refuse to take, and by which poor patients might be deceived into taking what was necessary for their relief. I mention these circumstances, because they were practical difficulties which I had to contend with at the very threshold of my professional ministrations.

Salines I continue to employ, but without any confidence in them as curative agents in the more rapid forms of the disease. I intend, at some future time, to explain my views of the extent of their efficacy, when and how they should be employed, and what may be expected from them. I shall confine myself to a few observations on that kind of practice which has pressed itself upon me for adoption, and in which alone, in severe forms of the epidemic, I have any confidence.

I had found, as I believe almost every man of experience had found before, that a full dose of opium and chalk mixture, given in the early stage of the diarrhœa, would effect a cure. This is the simple and established practice for diarrhœa, and there is none better. Sometimes, however, a case of diarrhœa—otherwise rice-water purging—would occur, where chalk mixture and opium were of no use in whatever quantities given. I quickly discovered that pushing these remedies was a waste of time, and giving death fatal opportunities; and my next point to solve was, What is the proper indication of practice to be pursued in this stage?—to act on the skin,—to encourage the diarrhœa,—to excite vomiting,—or suppress the evacuations? The vapour-bath will effect the first, saline aperients the second, emetics of all kinds the third; but a remedy was yet to be found for the fourth intention. I must not forget that the stimulating plan suggested itself, but my own Tables stood me in the face,—and now I may express my pleasure, *en passant*, that scarcely any Physician, or Practitioner, of repute, in this country, has employed this system of treatment. If my Tables have succeeded to this extent, I feel rewarded for the labour they cost.

To be brief:—My argument was, if the disease can be checked, in the first stages, by astringent re-

medies, and if these be the obvious and certain means of cure,—then, in the latter stages, when the purging becomes more abundant and severe, they are more imperatively necessary. This is the natural and *primâ facie* view of the matter, and is, in truth, acted on by every medical man in the first instance; and he only abandons his first correct ideas because the remedies he has been taught to use have utterly failed. He then lapses into the mysticism of minute doses of calomel, of whose action he is perfectly ignorant, or into the quackery of wet sheets and cold water; which are the refuge of the perplexed Practitioner. I admit that these agents are useful in their proper time; I have employed them with great success, but I hope with discrimination.

My experience of cholera has led me to this conclusion, *that any remedy will produce the same effect in cholera that it will in any other disease;* and that its effects in the ordinary dose are equally obvious. When any remedy, given in a full dose, will not produce the expected effect, the right indication has not been pursued, and the practitioner is wasting his drug, and trifling with his patient. There ought to be no mystery in the treatment of cholera; but the mystery is made by practitioners themselves, who, when they find that a particular drug does not produce its ordinary effects, prescribe some necromantic form of administering it, and gravely abide the issue. All the importance is thus ascribed to the form and quantity—to a single drop or single grain, less or more, given in so many minutes, and not to the drug upon its own merits.

With the view, Sir, of obtaining an astringent powerful enough for my purpose, I employed a variety of remedies; among others the acetate of lead as recommended by Dr. Graves, and found it more efficacious than any other medicament that I employed; but it failed in severe cases, and in one instance I gave 42 grains in about 36 hours without arresting the purging. Sulphate of copper had also a trial; and although it arrested attendant hæmorrhage in two or three cases, it appeared to me to irritate the mucus membrane, and increase the rice water evacuations.

Nitrate of silver was at last given in this form:—℞ Argent. nit. gr. j.; pulv. opii gr. ¼; Ft. pil. post sing. alvi deject. liquid. sum.

If the purging were very frequent, the pills were given regularly every hour to the extent of five or six doses, or even more if necessary. When the evacuations have been very profuse, two or three pills have been given at a dose, and repeated until the evacuations were partially or wholly arrested,—a result that invariably occurs. This remedy is as certain in its effect of restraining the rice-water purging as opium and chalk-mixture in checking the premonitory diarrhœa. I do not say that every case will recover in which the purging is checked;—this would be an assertion unbecoming scientific medicine. In some cases, do what you may, the patient will die; the dew-drops of the sepulchre are upon his brow, and death is a disease no medicine will cure.

Since I commenced the use of this remedy, my assistants and myself have treated 853 cases of diarrhœa in all its stages, and, of this number, seventy only have been placed under the nitrate of silver treatment, but these seventy were the worst cases, and in the rice-water stage. They were considered by myself and assistants, as they happened casually to come under the care of either, to be beyond the reach of other remedies, and were placed upon the plan recommended as a *dernier ressort*. I know that the reader will ask, But were the seventy cases true cases of cholera? Had they all the symptoms of collapse? Certainly not. I should be very sorry if they had. More than this, I have now attended 1600 cases, or more, of bowel complaints, in one of the most fatal districts of the metropolis—the West London Union; I have seen the disease in all its forms and stages, and have not yet acquired the assurance that would enable me to say that I have attended exactly 800 cases of cholera and 835 cases of premonitory symptoms, which is about the proportion assigned to these stages, respectively, by the abettors of particular plans of treatment.

When my assistants find that the purging is not restrainable by the opium, kino, and chalk in full doses, but that the dejections become more watery and copious, the pulse begins to fail, and the powers of the system to yield, they administer the nitrate of silver pills, and I am happy to say, that the effect is so decided that fully developed collapse rarely occurs. The same remedy has been given in profound collapse, and the patients have recovered. The first case in which it was administered was that of a youth of the name of Boak, who was blue and almost pulseless, and profusely purged; nevertheless, the purging was arrested, and the lad recovered. This was the first instance of recovery I had witnessed from state of collapse so deep.

Seventy cases of the severest kind have been placed upon this treatment from among *eight hundred and fifty three,* and, in that number, there have been only *five deaths.*

I state, again, that these seventy cases were not all cases of collapse, though these and many more of the aggregate number were cases of cholera so called; for I confess myself quite unable to draw the line of distinction, in practice, between cholera and diarrhœa.

They were not cases of collapse, because seeing them early they were not allowed to run into that stage. In the stage of actual and deep collapse, I believe that medical treatment is of little avail, but I am satisfied that the only chance for the patient is suppression of the evacuations.

Of the five cases ending in death, one died within twelve hours; she was one of four in a family attacked with the disease, and was in a hopeless state from the first. Another was a peculiar case; the girl was attacked with rice-water vomiting and purging at two o'clock, p.m., walked to my surgery, though in a state of great debility, received the pills, and the evacuations were completely arrested; at five o'clock she went down stairs, and, whilst washing in the kitchen, shrieked violently, had a kind of fit, was incoherent, fell into collapse, and died in twenty-one hours. A third case died through neglect; it was that of a man of good bodily vigour; he was in collapse, but his evacuations were arrested, and his pulse was becoming full and his face cheerful; so much so that a message was sent to me by a clerical visitor, "that, little judge as he was, he was sure this man would recover. I thought so too. I called to see him at twelve o'clock, p.m.; the door was closed, and I knocked; to my surprise my patient's voice vigorously responded, 'Come in.' I went in, and found the exhausted wife fast asleep with her children on another bed, and not a single person at hand to render aid to the poor man in case of need. They, no doubt, believed that he was safe; nevertheless, at about four o'clock that morning profuse purging came on again, there was no one awake to give the patient medicine, and when I called in the morning his case was hopeless.

This case induces me to remark here, that after the purging is stopped, it will often reappear at the end of twelve or twenty-four hours; and, in such circumstances, the treatment should be resumed.

The fourth case was that of a woman who had nursed the youth Boak already alluded to. I saw her but once, and she was then dying. I ordered the pills to be administered, but without any expectation of their being of use. She suffered twenty-one hours.

The fifth case was a combat of seven days' duration. The woman fell into collapse, and the pills were administered. For two days she had neither vomiting nor purging, and the dampness of the skin was removed; but at the end of that time she became comatose and died. This woman was of a very florid complexion, and had a tendency to apoplexy. This is a brief history of the five fatal cases; and it will be seen that, even in these cases, the specific effects of the remedy were produced. I apprehend that such cases as run their course within twenty-four hours were, from the first, beyond the aid of medicine.

Now, Sir, there is no mystery about this remedy: there is no room for speculation about its action on the liver or the kidneys, the blood or the bile,—it has its appointed work to do, and it does it or not,—of that every man is the judge, his own eyes are the witnesses.

I may remark, in conclusion, that I have never seen any evil results spring from its use. It may be employed, with judgment, in the secondary diarrhœa as well as in the primary,—and in any case, indeed, where an arrest of purging may seem necessary; but it must not be given rashly, and when simpler remedies will effect the same end. Vomiting sometimes succeeds an arrest of the purging, but, although troublesome, it does no harm; and, if a little fever should supervene upon the use of the silver it would, in some cases, be desirable, and assist re-action,—in other cases it can be readily assuaged by the usual saline remedies.

I am, Sir, your most obedient Servant,

GEORGE ROSS,

PHOSPHORUS IN CHOLERA.

[To the Editor of the Medical Times.]

SIR,—Having seen two cases of Asiatic cholera out of three recover from the stage of collapse during the use of a powerful remedy, scarcely ever employed medicinally by English practitioners, I beg to introduce it to the notice of your readers, thinking it worthy of their consideration, although I do not presume, at present, to attach much weight to the recovery of the two patients. The remedy I allude to is phosphorus, which was administered in the dose of one grain, combined with wax, in the form of pill, by Mr. Batten, surgeon, residing in Westbourne-street, Pimlico, with whom I visited the patients. The two persons who recovered resided in Queen-street, Pimlico; one having taken three pills during six hours, while the other took only one pill. The other patient, who lived in Westbourne-street, took two pills; she rallied for a short time, but eventually died, having been in a hopeless state when first seen. Medical men are aware that it is a powerful medicine, and should be used with great caution. Beck says, that two grains and a half, in solution, have destroyed life; and Taylor says, that less than half a grain has produced the same result. Gendrin also considers it to be a dangerous medicine. I would not venture to employ it unless the patient were in state of collapse, and then would it not act more quickly in the form of phosphoric ether—"æther phosphoratus"—dissolved in sugar? I have invariably checked every case of cholera which I have seen, prior to the blue stage, by calomel, combined with small doses of opium, sinapisms, warmth, absorbents, and stimulants. Mr. Batten published his mode of treating cholera by phosphorus in the solid form in 1833.

I am, Sir, your obedient Servant,

C. J. B. ALDIS, M.D.,

Lecturer on Medicine at the Hunterian School.

ON THE TREATMENT OF CHOLERA.

[To the Editor of the Medical Times.]

SIR,—As the different views and corresponding treatments of cholera which have been adopted by the Profession may favour the impression that medicine is an uncertain science, I will now enter briefly into the consideration of the circumstances which sanction the variety of views and practices just alluded to.

These chiefly depend on the different classes of cholera patients, the various kinds of cases, the stages of the disease, the remedies employed, the results of their employment, and the appearances on dissection; on the whole of which topics I will slightly touch.

And, first, with regard to the classes of patients. Those practitioners who are accustomed to private practice only, and, particularly, who attend the higher classes, and are called into the case at the very first onset of the disease, and during its first stage, that of *irritation*, before this state of the nerves have produced arterial re-action, are justified in viewing the disease as dependent simply on irritation affecting some portion of the internal surface of the alimentary canal. They are confirmed in this opinion from the result of their practice and experience, by being afforded an opportunity of removing the evil while it is yet in this primary stage, by anodynes and opiates, and thus preventing its further progress.

Amongst the middle classes, on the accession of the disease, and during the slight precursory diarrhœa, the patients frequently, before sending for their medical attendant, have recourse to some nostrums they have been accustomed to prescribe for themselves, or that are recommended by their friends or neighbours, and those failing after trial for a day or two, an alarm is excited, and the *doctor* is sent for.

He now finds the disease passed into its secondary, or reactionary stage, where the excitement of the arteries consequent on the irritation of the nerves supplying them, re-act back upon the nerves, and thus a mutual action and reaction is established between them, not easily to be allayed.

They now find their patient with the pulse slightly accelerated, with a dry skin, and a white feverish tongue. There is a dull, heavy, faintish pain in the umbilical region. This is sometimes relieved, but oftener increased after an evacuation. Steady extended pressure rather eases it, but continued pressure on one point increases the faint feeling, and developes the internal tenderness.

Besides this continued pain and uneasiness, there is, especially if the case be severe, a periodical pain, with gripings or tormina, coming on at intervals less or more regular, as the disease advances. The experienced practitioner can now discover traces of actual inflammation of the mucous tissue. These symptoms have led some, who practise no other method of removing inflammation than depletion, to the use of the lancet. In country places, and where the strength of the patient was such as to produce

subsequent reaction, this practice has been attended with much advantage in cases numerous enough to sanction its adoption.

This has also made these same practitioners condemn, in no measured terms, the use of stimulants in any form or case. On the contrary, in large towns, where the patients are weak, and as in such cases the symptoms of inflammatory action are not so well marked, and assume more an irritable and spasmodic character, practitioners are induced to use stimulants and antispasmodics. These remedies have a chance, when freely administered, to induce, in weak subjects, a similar re-action to what blood-letting produces in the strong. The last-mentioned medical men are justified by the result of their practice in considering the disease only nervous and spasmodic, and in believing their country brethren misled in principle and practice.

Both these methods of treatment may succeed according to the circumstances of the case; but unless the medical attendant can see into the principles to be acted upon, the success must depend upon chance. In medicine extremes meet, and very opposite means are productive of the same results. Thus in cholera itself, one man may equalize the balance of the nervous and circulating systems by inducing artificially a cold stage of fever, followed by a hot and sweating stage, and consequent general restoration to health, by enveloping the patient in a wet sheet—another may produce the hot and sweating stages, and the same results, by a hot bath; still, unless the practitioner can see into the principles on which he means to act, the success must be frequently accidental. The patient in the wet sheet, for example, may be so weak that the cold fails to excite the beneficial reaction; the blood may be driven by the cold on the internal organs, nay, never again be sent out upon the surface, and, by overpowering these organs, accelerate the death of the patient. One man, as a local rubefacient, may place over the seat of the pain a piece of ice; another, for the same purpose, may apply a sinapism, and a third may use hot fomentations; yet, though all the three applications are different in kind, they are the same in principle. As the inflammation attendant on cholera is of a low erythematic character, and the patients are generally in a state of debility, the blood-letting, from frequently failing to produce the re-action necessary for the equalisation of the energy and circulation, only tends to facilitate the destruction of the patient.

On the other hand, in this stage, the stimulating is equally destructive; for, if the remedies are not pushed so far as to remove, by equal distribution, any concentration of energy and blood, they also only increase the force of the circulation in the wrong direction it has assumed, and the fatal process is thereby accelerated. Here the benefit of the peculiar action of the port wine appears evident, by exercising a direct influence on the seat of the disease, soothing the irritation of the nerves, and equalising the arterial distribution, and affording general tone to the enfeebled vessels, and to the weakened system. Here also the local-alterative effect of the tartar emetic eruption, by producing a *metastasis* of the diseased action to the surface is particularly required,—a practice which never fails to effect this change, even in cases of the greatest debility, especially as the coming-out of the eruption is promoted by stimulants and strengthening medicines. But, to return, the last class of patients are those in whom little attention has been paid either to the primary stage of irritation, the re-actionary one of local arterial excitement; but who, when the invalids fall down in the *congestive*, or terminal stage, called *collapse*, are carried off to an hospital. The gentlemen, therefore, attending in public Institutions of this kind, seldom see their patients till they are actually in a state of *congestion*, and labouring under stagnation of the general circulation. Under such circumstances, we need not be surprised to find these Practitioners looking upon the disease as entirely congestive, and employing every possible means that can be suggested to bring their patients out of that deplorable state. If, however, this view were perfectly correct, a very great proportion of their patients would recover.

But this is by no means the case, as may be seen by the authenticated return of the number of cholera patients received into the civil hospitals of St. Petersburgh, where, out of 6,943 cases, 3,507 recovered, while 3,313 died, which, with what would also die of the 123 still remaining uncured, amounted to within a fraction of the one-half of the whole number admitted. As I have said in a former communication, death or recovery depends on what change in the internal organs may have taken place during the excitement preceding this terminal stage.

If, as some assert, the genuine cholera be the sudden accession of a cold congestive state from a poison in the blood, communicated by the atmosphere, or some unknown cause, and making its attack without any precursory symptoms, like the cold stage of an intermittent, then there is a presumption, that a very great number would recruit, from the use of powerful stimulants, since no fatal change, produced before the accession to this state, would prevent the possibility of their recovery.

Although the precursory stages are in some cases very slight, yet I have never seen a case of the above kind in cholera. Nevertheless, I do not deny the possibility of such attacks; for I once witnessed a woman of the name of M'Indow, at Edinburgh, in 1824, who died in the cold stage of infectious puerperal fever, the system being too weak to bring about the re-action necessary for the production of the hot stage.

R. K. Richmond.

10, Red Lion-square, Sept. 4, 1849.

THE CHOLERA IN AMERICA.

[To the Editor of the Medical Times.]

Sir,—Two or three weeks ago, I returned to England, from a tour through many of the States of America, where I had opportunities of studying the scourge which is now devastating the Western and Eastern World, and especially in the cities of New Orleans, St. Louis, and Cincinnati. I cannot hope to offer to your readers much that is new, but, since we are anxious to obtain the fullest information respecting this fearful malady, you may, perhaps, think this communication worthy a place in your columns.

I shall not enter upon a consideration of those circumstances attending upon cholera which are peculiar to the West, but shall confine my remarks to those which are common to the two countries, yet existing in an exaggerated form, in the Western World.

It is remarkable, that, of the deaths accruing from cholera in America, only about 12 per cent. occur amongst Americans. This may be accounted for by stating, that the Americans are usually very temperate, taking only three meals per day, and, then, eating and drinking moderately. They are usually in independent circumstances, and without the corroding anxiety which enfeebles the body and mind, and depresses the spirits of many in the old country; and, therefore, they have an energetic and vigorous mental and bodily system, and great exuberance of spirits, exciting them to enterprise and the performance of acts of daring. The remaining 88 per cent. of deaths from cholera occur amongst the recently arrived emigrants, and I would call the special attention of your readers to the reasons which may be adduced for this. The emigrants usually arrive from countries, where they have long submitted to poverty, with all its attendant evils, arising from mal-nutrition and mal-assimilation, want of cleanliness and pure air, excessive exertion and deficiency of moral courage. They received from their parents, frames feeble and disposed to the attacks of disease, and have increased these primitive evils. During a long sea voyage they have further suffered from sea sickness, impure air; from unclean linen, water-closets, crowded and uncleansed berths, the want of fresh nutritious food, food badly cooked and *ennui* which the continued monotony has induced. The mass of emigrants is composed of Germans and Irish. On their arrival in America, the former are remarked for their slothfulness, want of cleanliness, looseness of morals, and an intemperate use of new raw whiskey. If very poor, they continue to starve on a wretched *soupe maigre*; and, if in better circumstances, they stuff themselves to repletion with excellent food, to which, from its price, they had been unaccustomed. The latter class are also idle, dirty, and intemperate, and live on an excess of vegetable food. They cannot sleep if there be less than five persons in a bed; and they economize their means by covering a whole floor. The remaining emigrants are mostly poor English and Italians, whose habits are by no means covetable. During the first twelve months all classes of emigrants are noticed for their imprudence, as by exposing themselves to the deluge of a western thunder-storm, to be subsequently dried by the sun, scorching at 120° or 130°. The Irish and Germans saunter about in the burning sun, or in the shade, at 99° in summer; and the industrious Englishman believes that he ought to labour throughout the day, as he has been accustomed in his mother country.

The cholera has raged the most fearfully in those cities which are frequented and mainly inhabited by emigrants. In New Orleans, the floating population is not less than 60,000. The mortality, so far as it has been ascertained, was fearful; but thousands have died whose names, families, and destination were unknown, and have been hurried into the graveyard, with or without coffins, as soon as, and sometimes before, they were dead. If the authorities were at all aware of the amount of mortality, they did not divulge the secret, but endeavoured to re-assure the commercial world, by representing the evil to be diminutive; for, in May last, we were informed, by the New Orleans journals, that the city had never been so healthful as at that period, whilst every resident saw hundreds of victims carried to their graves. In St. Louis, the Germans and Irish constitute one-third of the entire population; and in Cincinnati there are 50,000 Germans alone. The mortality from cholera in June last in these two cities, was from 100 to 150 per diem. The Irish and German emigrants do not usually proceed up the country, and sit down on their own farms, but hire themselves as domestic and farm servants, and bricklayers' labourers, and remain in degradation, vice, and poverty.

In such cities there are also other circumstances which ought to be noticed. There is not a sufficient supply of gratuitous Medical assistance, and the ordinary charges of Medical Practitioners are exorbitant. There is no efficient system of drainage in any of the American cities, and many of them cannot be drained. New Orleans is situated on a level swamp, full six feet below the level of high water in the Mississippi, which river rolls along its side. There is, therefore, no fall for the water, and no underground drainage of value can be effected. The soil upon which it is built has been very recently deposited from the sea. Shells are found quite up to the surface, and every hole is filled with infiltrated water, loaded with matters which putrefy, and emit a horrible effluvium, under the influence of a burning sun. No stone, nor any other kind of soil, is met with at the bottom of the deepest foundations, and the deficiency of all materials for the formation of roads causes the streets to be ankle-deep in mud; and where the streets are paved the stones are so far apart that accumulations of stagnant, stinking water abound everywhere. The superficial drains lack a proper fall, and are ever filled with filth. One cannot walk through the city without being disgusted with the dirt and stench. These evils, only lessened in magnitude, exist in many parts of St. Louis, Cincinnati, and New York.

House-rent and lodgings are usually dear in these cities as compared with the more inland parts, so that people are induced to crowd themselves together quite as much as in the cellars of Liverpool, or the garrets of London. They thus live in impure air, retain their uncleanly habits, and add to the general filth. This crowding together of persons is a notorious cause of cholera. It was remarked, that the cholera was the most fatal amongst those slaves who live in small ill-contrived cabins, and without a sufficient space being allowed to them. In my journeyings in June, I called upon one of the largest planters in North-Western Louisiana, who informed me, that he had lost fourteen slaves, that four additional had died during the day, one was then dying, and he had many others suffering from the premonitory symptoms. I subsequently learnt, that he was notorious for crowding his slaves together. During the late inundation of New Orleans, a remarkable instance occurred of the evils resulting from high rentals. A large portion of the city was covered with water to the depth of the bed-room floor. The houses were vacated, and communication was carried on through the aid of boats. Many persons removed from other parts of the city to inhabit these chambers, so that they might live rent free.

In these cities poverty and want are as frequently met with as in the more unfortunate parts of our country, and, therefore, the like evils occur in both countries.

It is well known, that very many deaths occurred on the steamboats plying up the Western Waters, and we rarely travelled on a boat without a death occurring. Sometimes a cabin passenger dies, but usually it is the intemperate fireman, or the occupant of the steerage. There is no provision made for the comfort of the steerage passengers on these boats, and they are crowded amongst the merchandise and filth, without beds, or any convenience as to their food. They are surrounded by cattle and pigs, whose dung is allowed to remain upon the boat. It is the policy of the barkeeper to have his "bar" at the hinder part of the vessel, so that he may entice these poor people into his fangs. It was remarked that cholera did not occur on board boats which had the bar in front. A boat carried more than 300 emigrants to St. Louis in June last, and it was known

that not more than ninety were alive three days afterwards. From these facts we may affirm, that the usual predisposing causes of cholera in America are, want of cleanliness, impure air from crowded and uncleansed rooms, and accumulated putrefying filth in streets; the lack of proper food, intemperance, and poverty, with its attendant and consequent evils of feebleness of system and lack of moral courage, or an oppressive sense of fear; and this last is believed to be the most important. An Irish emigrant at Cincinnati, in June last, refused to leave his bed, stating, that he had the cholera. The Bishop saw him, and believing that he was well, ordered the people to compel him to rise. He soon returned to his bed, affirming that he had the cholera, and should die; and die he did. A farmer, residing twelve miles from Cincinnati, drove a load of fire-wood into the city early in the morning, and found his cousin dying of cholera. He stayed with him a short time, and after his death returned home. He felt unwell, and a doctor was summoned; but he died in three hours. The wife was well when the Physician left the house, and in one hour was a corpse.

There are other predisposing causes, such as the results of other diseases, grief, anxiety, and excessive mental or bodily exertion. A very common cause is simply too great repletion of the stomach and alimentary canal. The functions of these organs are deranged, the secretions become unhealthy, constipation is induced, and then removed by diarrhœa, which, under ordinary circumstances, would be regarded as healthful; but which arising from the presence of disordered secretion, induces irritation of the mucous membrane, and excitement of the nervous system. An unusual change of diet merely, will cause an untoward derangement of the digestive function. Fear will induce mal-assimilation of the food, and prostration of the system, or by the prostration alone, will bring on an attack of pure mucous diarrhœa.

Sudden changes in the condition of the capillary circulation were found to be most important, such as those induced by violent variation of temperature in the midday and evening, in the Western States especially, and the chilling effects upon the skin of the thunderstorms alternating with the burning of the southern sun.

These statements receive confirmation from the well-attested fact, that individuals in good health, of sound constitution, of rigidly temperate habits, who exercise prudence in the selection of food, and of sufficient moral courage, might fearlessly travel in steamboats in which cholera raged, or mingle with the tainted inhabitants of condemned cities. But it was essential for their safety that they should not expose themselves to the influence of the causes before mentioned, so long a period as to induce languor or debility of the system.

The treatment of cholera is a most important consideration, and I fear that we have regarded it too empirically. It is absurd to expect that any one plan of treatment shall be applicable to a majority of the cases, whether that be the stimulating, the opiate, the mercurial, the saline, or any other. No disease, having so great a variety of predisposing causes, will submit to one plan of treatment. The rule must be, to vary it according to the predisposing cause. I think that far too much attention has been given to the diarrhœa, and far too little to the cause of it; not that I would neglect the diarrhœa; but the one should be done, and the other not left undone. The diarrhœa is the immediate predisposing cause of cholera, but it is itself induced by circumstances acting previous to its occurrence. If the diarrhœa result from the presence of irritating matter in the alimentary canal, whether that be faecal matter, or only disordered secretions, the treatment ought to be that of ordinary diarrhœa; viz., the exhibition of aperients. In persons of feeble system I prefer the use of castor oil, rhubarb, and calcined magnesia; and in others the sulphate of magnesia or soda, coupled with an aromatic and an occasional dose of calomel. Where the diarrhœa appears to be of a purer character, as the result of fear, or other depressing influences, stimulating astringents should be freely employed, such as catechu and kino combined with cayenne pepper or ginger. Nitrate of silver and sulphate of copper are also useful, but they must be accompanied by stimulants. It is most important that the patient should not be suffered to take liquids, except in the smallest quantity This is the treatment in the early stage; but at a later period the matter assumes a more urgent and complex form. Whenever the symptoms are believed to depend upon the presence of irritating matters in the alimentary canal, the treatment just mentioned should be adopted, and opium will be injurious, except when given in one single full dose at an early period for the purpose of suspending the sensibility of the sensorium. In addition, I strongly advise the use of a rich stimulating soup by the mouth and rectum, made like to hare, ox-tail, or mock-turtle soup, and given in a very concentrated form. Other stimulants should not be exhibited until the aperient antacids have produced their effect, except as a *dernier ressort*. When the above-mentioned condition of the alimentary canal is not evident, I think the plan of treatment is more clear, and the results will be satisfactory. All the symptoms attest the existence of great exhaustion, and of unnatural sensibility of the nervous system. How relieve such a state? The effect of opium is to exhaust the system, and, unless it be administered in overpowering quantities, it will not relieve the suffering; but the proper exhibition of stimulants will effect both these *desiderata* speedily and safely in most instances. This is the case in which stimulants should be most freely administered, and it is somewhat analogous to the condition of things in the later stages of typhoid fever. When stimulants are administered, the doses are usually given with too little frequency, so that the stimulating effect of the one dose is succeeded by re-action before another dose advances to its assistance. The astringent principle in good port wine appears to render this wine a most desirable remedy under these circumstances; and one glassful of undiluted wine should be given to an adult every quarter of an hour until the urgency ceases. This direction should be faithfully observed. If opportunity offer, it is well to give small quantities of the concentrated soup before mentioned. If Cogniac be preferred to port wine, it should be given undiluted, in wine-glassfuls, so frequently that a bottle, or even two bottles, may be taken during the twenty-four hours.

Mustard poultices and friction should be incessantly employed in every case. It is needless to add, that whatever circumstance may have predisposed to the attack should be cut off, if possible; and the patient placed in those which usually conduce to health. Above all, it is essential to allay the fears, and to arouse the moral courage of the patient.

I am, Sir, your most obedient servant,

Ed. Smith, M.D., LL.B.

Fall House, Heanor, Derbyshire, Sept. 12, 1849.

CHLOROFORM IN CHOLERA.

[To the Editor of the Medical Times.]

Sir,—I beg particularly to call the attention of the Profession to the internal use of chloroform in the present epidemic. I, as well as some other medical friends in this town, have used it very extensively, both in the premonitory diarrhœa and in the collapsed stage, with very extraordinary benefit. It should be given, mixed with mucilage, in doses of from five to fifteen minims every hour or two. One dose will very frequently stop the diarrhœa and sickness. The patient should drink plentifully of milk and cold water, with a little sesqui-carbonate of soda in it. The warm-bath, with a large quantity of common salt in it, frequently repeated, is a valuable auxiliary; but chloroform is the remedy.

Your obedient servant,

John Davies, M.D.

Hertford, Sept. 12, 1849.

P.S.—I am quite aware that Mr. Brady, of Harrow, and others, have used the same remedy successfully in the course of last winter.

OZONE.

[To the Editor of the Medical Times.]

Sir,—During the past week, I have read accounts of the deficiency of a gas (called ozone) in the atmosphere as a cause of the cholera prevailing to such an alarming extent just now. This gas was discovered by Professor Schonbœin, and, as I can find no mention made of it by Fownes, you would oblige a reader of your Journal by stating what is the composition of it, and how produced.

I am, Sir, yours obediently,

Sept. 13, 1849. J. L. V. G.

[Ozone, to which influenza is ascribed by Schonbœin,—(see remarks by Dr. Bushnan, in our Journal for April 8, 1848, No. 445,)—and cholera by others, has been variously described and defined. It is said, by some, to be a combination of nitrogen and oxygen; by others, of oxygen and hydrogen in new proportions. Dr. Spengler, of Elville, in *Henle's Zeitschrift*, declares it to be formed in the air by the decomposition of its water through disturbances of its electrical equilibrium. Dunglison, after Schonbœin, defines it, "the powerfully odorous matter produced when a current of ordinary electricity passes from pointed bodies into the air." Every one who has been in the habit of experimenting with a large electrical machine, must have remarked this odour during the escape of positive electricity from a point. Schonbœin noticed, also, that it accompanies the electrolyzation of water; that it is only disengaged at the positive electrode; and that it can be preserved in well-closed glass vessels for any length of time. (*Noad's Lectures*.) Draper, of New York, regards it as the active state of oxygen, or oxygen rendered active by electricity. Thus, by passing a current of electric fluid through pure oxygen, ozone is obtained, having a sulphurous odour, setting fire to phosphorus and irritating the nostrils, as in catarrh. The test of its presence is a bit of paper dipped in a solution of iodide of potassium, and then in one of starch. The oxygen of common air acts slowly on it, and produces gradual change and coloration. Ozone and ozonised air will occasion them to act promptly on each other, producing a dark blue colour. See *New York Journal of Medicine* for July, 1849.—Ed. *Med. Times*.]

SMITHFIELD AND THE CHOLERA.

[To the Editor of the Medical Times.]

Sir,—I observe in your great contemporary the *Times* of this morning, an account of a meeting of the City authorities, wherein two of the members of the "body corporate" exultingly allude to the stand they have made for the preservation of Smithfield Market, which you, and the major part of the Press, have so justly termed, "The Great Nuisance." Quoting, as their justification, "that no case of cholera had occurred in Smithfield;" *ergo*, it must be the very seat of health. True, in the pens of Smithfield there has probably been no such case, for the best of reasons; but, if these gentlemen would take the trouble to inquire, they would find that in the courts around, and in Cloth-fair, there have been cases enough—nay, too many. Besides, had these gentlemen read the Lectures in your Journal, given by Mr. Ross, of Farringdon-street, (in the vicinity of Smithfield,) they might have been less confident, as he therein defines the locality of cholera, and endeavours to establish a law, whereby Smithfield, in virtue of its elevation, would enjoy comparative freedom from the scourge.

A Sanitary Reformer.

QUERIES

PROPOSED BY THE CHOLERA COMMITTEE OF THE COLLEGE OF PHYSICIANS, IN THEIR LATE CIRCULAR TO MEMBERS OF THE COLLEGE.

1. Can you communicate to the Committee any facts observed or investigated by yourself, which appear to you demonstrative of the contagious or infectious nature of Cholera, or of its communicability in any way?

2. Can you detail any facts illustrative of the influence of deficient ventilation, damp, and foul air, respectively, or of other external circumstances, in determining or favouring the production of Cholera?

3. What are the particular states of body or mind, which, according to your experience, have most frequently predisposed individuals to be attacked by the disease?

4. What are the groups of symptoms which have preceded the full development of the attack of Cholera?

5. Have you observed any distinctive marks, by which Diarrhœa, about to pass into developed Cholera, may be recognized?

6. Does it accord with your experience, that Cholera, in the stage of Serous Diarrhœa, may with certainty be checked? What means have you found most effectual in attaining this object?

7. Have any facts come under your notice, which, independently of theoretical views, would elucidate the question, Whether the affection of the intestinal mucous membrane in Cholera, is the primary disease, or one of its secondary effects?

8. Can you furnish the Committee with the particulars of cases in which the rapidity of the fatal collapse has borne no relation to the amount of fluid discharged from the blood-vessels, either through the intestinal mucous membrane, or through the skin?

9. What are the pathological conditions which you have observed in the "Consecutive Fever."?

10. What means have you found most successful in re-exciting the function of the kidney after the stage of collapse has passed?

MEDICAL NEWS.

Apothecaries' Hall.—Names of gentlemen who passed their examination in the science and practice of medicine, and received Certificates to practise, on Thursday, September 6, 1849:—Thos. Stokes Guppy, Sidbury, Devon; Philip Henry Tribe, Bristol; Richard Barwell, Norwich.

War-office, Sept. 11.—67th Foot.—Assist.-Surg. Thomas Patrick Matthew, from the Staff, to be Surg., vice Charltoe, deceased.—16th Foot.—Acting Assist.-Surg. Henry Martyn Fraser, M.D., to be Assist.-Surg., vice Kennedy, appointed to the Staff.—Royal Malta Fencible Regiment.—Carmelo Ellul, M.D., to be Assist.-Surg., vice Bernard, promoted.—Hospital Staff.—Assist.-Surg. Edward John Kennedy, M.D., from the 16th Foot, to be Assist.-Surg. to the Forces, vice Matthew, promoted in the 67th Foot.

St. Thomas's Hospital.—The vacancy in the office of Physician to St. Thomas's Hospital, occasioned by the death of Dr. Henry Burton, has been filled up by the appointment of Dr. J. Risdon Bennett, one of the assistant physicians.

Obituary.—On the 3rd inst., after a few hours' illness, Michael L. Mason, Esq., surgeon, 5, High-street, Newington; an old and much-respected practitioner.—On the 4th inst., John Morgan, surgeon, Ordnance Hospital, Dover, late of Royal Artillery, aged 71, sincerely beloved and lamented by his relatives and friends.—On the 1st inst., at Stockwell, Surrey, after a few hours' illness, Dr. James Leatham Clarke, surgeon, R.N., late of Her Majesty's ship Hydra, in his 41st year.—On the 26th ult., in Dublin, Cusach Roney, Esq., M.D., aged 69.—On the 7th inst., at Tipton, Staffordshire, from the effects of long foreign service, and the severe hardships he endured in the late campaign in South Africa, William John Power, surgeon, 91st Regiment, in the 37th year of his age.—On the 8th inst., in St. James's-square, Dr. Drever, M.D., aged 76.

The Cholera.—It is melancholy to contemplate the ravages which this disease has made during the past week. In nearly all the large provincial towns and cities it has been on the increase; and many villages, which in 1832 escaped from this fearful epidemic, have now been attacked. Even Birmingham, which, from some unknown cause, was exempt from cholera seventeen years ago, has had two cases occur within the last few days amongst its inhabitants. In Scotland the epidemic exhibits little appearance of declining; and both in England and Scotland the mortality, in proportion to the attacks, is as great as ever. Medical science has striven in vain to check the malady, and it still continues the *opprobrium medicorum*. The Registrars' Report for London during the past week is as follows:—

The bills of mortality were commenced in the reign of Queen Elizabeth, and ever since the year 1603 have been published by authority in London. In this respect the English metropolis stands alone; no weekly tables of the causes of the death of every inhabitant are published in the capital of any other European State. Various motives for the measure have been assigned; but the fact of continuous publication from a period anterior to the appearance of newspapers and gazettes is remarkable and characteristic. It may be fairly referred to the natural inclination of the English people when they are in trouble to know the truth, and to see in figures the precise extent of their losses, although at times the sight might well make the courage of the bravest quail. On the continent "precautions have been used" in publishing the mortality from cholera in 1849, and the deaths from all causes have not yet been made known. The parish clerks of London in the 17th century, when the plague was at its height, counted the deaths and recorded their supposed causes; and the citizen, when the death-cart traversed the streets, anxiously studied the bill, surrounded by its gloomy symbolical border, announcing 8,297 deaths in a week out of a population of 600,000. In the hands of Price, Heberden, Willis, Bateman, and other statists, these records have disclosed the laws of mortality, and the causes of the insalubrity of the present cities.

One of their immediate advantages, however, is the evidence which they furnish that the most fatal and threatening plagues go through, with some perturbations, certain prescribed orbits; and, after raging for a given number of weeks, disappear. Plague, influenza, and cholera have been vanquished before; and to despair now would be as unreasonable as it was in the beginning of the year to deny that the cholera epidemic was impending. Those officers who are struggling with the triumphant enemy under every disadvantage will yet be victors; for, if they have art, they have also nature on their side.

The mortality in the week ending Saturday, September 8th, declined in the west and east districts of London, and increased slightly in the north and central districts, the deaths registered (1,741) on the north side of the Thames being 19 less than in the previous week. It was otherwise on the south side of the river, where the deaths in the week were 1,442! The total deaths registered in London were 3,183: of males, 1,460; females, 1,723. The deaths of females exceeded the deaths of males by 263, the reverse of the usual proportions. The deaths from cholera were 2,026; the numbers decreased in the districts of Shoreditch, Bethnal-green, Whitechapel, Stepney, Westminster; increased in Bermondsey, St. George, Southwark; Newington, Lambeth, Wandsworth, Camberwell, and Rotherhithe. The epidemic, which had been partially subdued, broke out again with terrible violence in Lambeth, where 279 persons died of cholera in the week.

Mr. Dawes, one of the Registrars of Lambeth, who has made careful inquiries on the subject, says: "At least half the cases I have registered were allowed to proceed unchecked until the most alarming and dangerous symptoms had manifested themselves; but lately more circumspection seems to have been used. Nevertheless, the cases are still numerous in which persons seem (from the painless nature of the attack) to be unconscious how highly necessary it is that immediate attention should be paid to it." People are so much accustomed to associate danger exclusively with pain, that the most fatal symptom, unaccompanied by pain, is neglected. They must, however, be taught to look upon painless diarrhœa with the anxiety that people in the plague looked upon the swellings called "tokens,"—which were also painless,—but with less fear; for the premonitory symptom now seems to be sent, not so much to announce death, as to give timely warning, and to call attention to that stage of the malady in which medicine can heal.

As medical skill is of most avail at the beginning and end of a fever, as the effect of the engines is most conspicuous at the outbreak and end of a conflagration, and as most energy is demanded when the wreck nears the shore, so it is in an epidemic, which, if it has not been checked at first, may yet be cut short, and combated with effect, as it declines. None of the measures of relief in any district should therefore be discontinued, but be prosecuted with redoubled vigour, until it has been completely subdued; and the districts which have not yet suffered greatly should immediately complete their preparations, for the time is short, and the evils of delay irreparable.

The Sanitary Reform of London and other Cities.—Mr. Jasper Rogers's proposition is worthy the earnest attention of all sanitary reformers. He remarks, "That every process hitherto attempted to deodorise human excretiæ has been attended by a proportionate injury to health, if done by exposure to the atmosphere, and by great decrease in value, if acted upon by fire-heat. Deodorisers have been *liquids*, and drying by evaporation, under any circumstances, deprives excretia of the main principles of value, viz., *its ammonia and the other volatile gases*. That *peat-charcoal*, prepared for the purpose, possesses the power of absorbing and retaining all those products, is the greatest absorbent known; will take up and retain above 80 per cent. of water, and above 90 volumes of those gases. Hence its inestimable capability for effecting deodorisation. That two-thirds or equal parts of prepared peat charcoal to the remaining portions of excretia will totally absorb the whole matter, producing a manure of almost incalculable value. The proportion may be less, even to one-third in some instances; and immediately on intermixture the manure becomes fit for transport in sacks, or bags, by any public conveyance. That carbon, hydrogen, nitrogen, oxygen, gluten, phosphoric acid, silicate of potash, chloride of sodium, carbonate of lime, sulphate of lime, and ammonia are *interwoven* into every grain of the charcoal." He proposes also, "that a tank be placed under the flag-way, or in any convenient position, *between* the house and the main sewer, into which the soil-pipe of each house can be made to discharge. The overplus water would filter away in a pure state through the charcoal deposited at the bottom of the tank, leaving almost all nutritive properties behind. Thus *water* only would reach the main sewers. If the number of tanks be objectionable, one can be made to receive the matter from several houses, or streets. A space, 30 feet by 20, sunk under the street, sufficient for mixing the manure of several streets. The operation may go on, at all times, uninterruptedly, by means of *filtering tanks*, into which the pipes may alternately discharge; and these tanks being situated to command an *intermixing machine*, the matter would drop directly into it and run from thence, in an apparently dry and perfectly inodorous state, into sacks, to be carted away. The removal of the excretory matter from that class of houses using cesspools. A drawer, containing a small quantity of charcoal to absorb the matter, to be placed under each privy, and the entire periodically removed in the same manner as *the ashes*. The establishment of closets and urinals open to the public, in 300 positions through the metropolis, in order to do away with the use of privies in cellars. The buildings to be under the care of two superintendents each, to be free to males of all classes. He shows, by adopting these plans, there would be an aggregate profit per annum of 3,829,387*l.*; that "the sewers of London would become waterways only, and the contemplated outlay for reconstruction be saved; the Thames be made pure, for no excretory matter could reach it; cesspools would no longer exist, nor disease arise from them; poisonous matter would cease to be driven from the wealthy to the poor; and that which now produces death in cities would be made to yield life and sustenance to the community at large."

The Association of District Medical-officers of Liverpool on Wednesday presented Mr. Frederick Cripps, of Soho-street, with an elegant silver salver of the most exquisite workmanship, and bearing an inscription.

Propagation of Yellow Fever.—The mystery attached to the propagation of yellow fever by fomites, and its importation by ships, as recorded by so many writers, may, Dr. Mitchell thinks, be elucidated by the supposition, that a tropical fungus, carried off in dark, damp, animalized holds of ships, or in the offensive clothes of sick or dead seamen, may be introduced into the summer clime of unaccustomed places, and there, as it came from, may go to, the shore, and be sometimes reproductive. Through this theory, Dr. Mitchell says, we can easily see why the disease may be imported, why it is imported rarely, and why it makes so slow a progress from the spot to which originally brought. It will also explain its non-contagious character, and even its occasional but rare visit to a village or hamlet. It may also account for its apparently spontaneous appearance in such places as Charleston, Savannah, and New Orleans, in which the winter may not be severe enough to kill the germs, but yet may so affect them as to make their re-action difficult or partial. It is only thus that we can comprehend how a perfectly healthy crew may bring with them, in the closed hold of their ship, the germs of disease, which, after their dismissal, may pestilentially affect the "stevedores," who discharge her, or only the labourers who disturb her ballast. We can thus, too, explain the usual pause between the first set of cases caught by visiters to the ship or labourers on board, and the attack upon the inhabitants of the vicinity. This curious interval, noticed by almost every writer, occupies about ten to fifteen days, whilst the period of incubation, after exposure to

a known source of infection, is only five days. This interval is only to be explained by the supposition that germs of some kind have gained a footing on shore, and have germinated and grown more numerous. It is the crop in the hold which produces the first set of cases. It is the crop on the land which causes the second. It is only through the action of some organic cause that we can explain the tenacity of the attachment of yellow fever to certain ships, and these, too, among the cleanest and best aired vessels in the British service. The Sybille had three several epidemic attacks between the 23rd of June, 1829, and the middle of April 1830. Two of these occurred while at sea. In the West India service, certain ships have usually an outbreak on going into even a healthy harbour.

METEOROLOGY OF THE WEEK.

Day.	Mean of Barometer.	Mean of Thermometer. Dry.	Ditto. Dew Point.	Difference between the Mean Temperature of the day and the same day on an average of 7 years.	General Direction of Wind. A.M. MORTALITY TABLE,

(Metropolis.)

For the Week ending Saturday, Sept. 8, 1849.

CAUSES OF DEATH.	Total.	Average of Five Summers.
ALL CAUSES	3183	1008
SPECIFIED CAUSES	3181	1005
Zymotic (or Epidemic, Endemic, and Contagious) Diseases	2469	302
SPORADIC DISEASES:		
Dropsy, Cancer and other Diseases of uncertain or variable seat ...	40	44
Tubercular Diseases	162	190
Diseases of the brain, Spinal Marrow, Nerves, and Senses	120	119
Diseases of the Heart and Blood-vessels	30	
Diseases of the Lungs, and of the other Organs of Respiration	85	81
Diseases of the Stomach, Liver, and other Organs of Digestion	73	76
Diseases of the Kidneys, &c.	15	11
Childbirth, Diseases of the Uterus, &c.	14	7
Rheumatism, Diseases of the Bones, Joints, &c.		
Diseases of the Skin, Cellular Tissue, &c.		2
Malformations		3
Premature Birth and Debility		22
Atrophy		25
Age		43
Sudden		
Violence, Privation, Cold, and Intemperance		36
Causes not Specified		3

The following is the number of Deaths occurring from some of the more important special causes;—

Apoplexy	20	Heart	29	Phthisis	1
Bronchitis ...	27	Hooping-cough	23	Pneumonia ...	
Cholera.........	2026	Hydrocephalus	38	Scarlatina	
Childbirth	6	Influenza	...	Small-pox	
Convulsions...	46	Liver	12	Stomach	
Diarrhœa	272	Lungs	5	Teething	
Dropsy	14	Measles	14	Typhus	
Erysipelas ...	9	Paralysis	21	Uterus	

BIRTHS AND DEATHS.

	Births.	Deaths.	Deaths over Births.
Males ...	636	1460	724
Females	665	1723	1058
Total......	1301		1882

TO CORRESPONDENTS.

"Scriptor."—(1) The rate of mortality from Cholera in this country is considerably increased by the tendency to consecutive fever, which does not occur so frequently in India. (2) Dissections have thrown but little light on the proximate cause of the disease.

"A Bartholomew Student."—The University of Oxford has the power of granting medical degrees, and of licensing to practise in medicine; and a person may obtain a degree in physic without having the license to practise, for which he pays a special fee. The university, however, has not the power of licensing to practise in London, or within seven miles of it, and its graduates do not become members of the College of Physicians, except by undergoing a fresh examination.

"Coryceus."—We know of only two diseases which produce metallic tinkling—pneumo-thorax, with a fistulous communication between the pleura and the lung; and in large excavations of the pulmonary organ, empty, or nearly so, within the walls, freely communicating with the bronchial tubes, and near the surface examined. Of these the former is the much more frequent cause of metallic tinkling; in both diseases, however, it accompanies the inspiration only, and requires for its production a large cavity, in which a little fluid exists, with reverberating walls communicating freely with the bronchial tubes.

"J. B. L."—It is Dr. Baumgaertner who makes the statement. The caseous matter of tubercles consists of small granular bodies, which are not very dissimilar from the formative globules of the frog's ovum, such as they appear immediately after the formation of granules. If the caseous matter be in a more advanced stage of softening, it is found to consist almost entirely of globules, or cells containing a granule, their parietes being also somewhat granular. In proportion as the tubercular matter approaches the stage of suppuration, the granular bodies disappear, and the pus globules, having a cell contained in a cell, become more numerous and interspersed with transparent molecules.

"Westmonastrensis."—(1) Singultus, as a symptom, is little to be relied on, for in the same disease it may arise from a variety of causes. (2) It is said to be produced by a sudden contraction and depression of the entire diaphragm, and the peculiar and abrupt sound that accompanies it, by air suddenly and forcibly entering at the mouth or nostrils, to replenish the void caused by the sudden retraction of the root of the tongue.

"Truth seeker."—Post mortem contractility of the muscles is a phenomenon occasionally observed in persons who have died from cholera or yellow fever. A singular case is recorded of a man, who, after respiration had ceased, and the body had been quiescent in every part for a time, subsequently was agitated in the following manner.—The left hand was first carried by a regular motion to the throat, then to the crown of the head; the right arm followed the same course on the right side; the left hand was then carried back to the throat, then to the breast, reversing all its motions. The right hand and arm performed exactly the same movements,—in all, eight consecutive, identical, equable motions, in apparently equal times, and with a regularity indicative of volition, though before death the man was totally insensible.

"Senex."—The subject is worthy of close investigation. It has been thought by some, that the disposition to attacks of syphilis and gonorrhœa are influenced by season. Many surgeons have noticed that venereal cases occur more frequently at one period of the year than another; but further researches are required, in order to determine the degree in which the more frequent occurrence of syphilis is to be ascribed to the effect of season.

"Provincial."—The Queen's College at Birmingham was founded in 1828, was incorporated in the seventh year of the present Sovereign, and received a supplemental Charter three years afterwards.

"G. B., Gosport."—Lymph for vaccination is found to be most entirely efficacious when taken between the period of its production and the eighth day inclusive. It has been found, however, that even the dried crusts have frequently communicated the perfect disease, especially in hot climates.

"Scotus."—An assistant-surgeon having served six years in India is permitted to retire on the half-pay of an ensign if his constitution is so impaired as to prevent the possibility of his continuing in India. Medical officers who have served less than three years in India, and have lost their health there are entitled to an allowance from Lord Clive's fund.

"Cantab."—1. The patronage of the University of Edinburgh is vested, by the Charter, in the Lord Provost, magistrates, and councillors of the city. 2. The Chairs of Clinical Surgery, Military Surgery, Medical Jurisprudence, and Natural History, are in the patronage of the Crown.

"Q."—The law is imperative in such a case; and a prosecution can only be commenced with a prospect of a successful issue, by having proofs that the person has infringed the Apothecaries' Act.

"Omicron."—The Hospital was founded and endowed solely by Thomas Guy.

"A Medical Student, City."—In the ordnance medical department no applicant is received on the list of candidates before he is twenty-two, or retained on it after he is twenty-five years of age. He must also be unmarried.

"An Occasional Contributor."—The offer is declined with thanks.

"Medicus."—The examination for the degree of Doctor of Medicine in the University of London will take place on the fourth Monday in November.

"An Apprentice."—The rules can be obtained on application at the College.

"An Old Subscriber."—We cannot decide the point.

"J.R.S."—Certainly not.

"Candidatus."—Merit is not sufficient alone, it must be associated with influence to insure success.

"L.M."—Water in the lungs of the drowned is only occasionally met with; for the glottis in every case is not so firmly closed as to prevent the introduction of a portion of liquid into the pulmonary cells.

"Josephus."—The hand or foot uncovered is not considered a weapon in law.

A Young Chemist."—Yes; platinum when perfectly clean acts so rapidly on oxygen and hydrogen gases, mixed in the proportion of 1 to 2, and at common temperatures, that the metal often becomes red hot, and kindles the mixture. Handling the platinum, wiping it with a towel, or exposing it to the atmosphere for a few days, suffices to soil the surface of the metal, and diminishes or prevents its action.

"Zeta."—We cannot give the information sought.

"Sanitas."—There is no such officer attached to the University.

"Dr. Pearson," of Maryport, writes us in reference to the doings of the Coffinites in his neighbourhood, who are using their dangerous nostrum, Lobelia Inflata, in the treatment of cholera. He says —"Not many days ago, I was called to a poor man suffering from an attack of cholera; after prescribing, I left, but returned shortly after, and found these parties in attendance: the man died. On Saturday last, I was called at six a.m. to visit the wife of a mechanic. I found her labouring under the symptoms of cholera; after prescribing, and ordering her to be sent to the Cholera Hospital, I left. On my return I found that when the husband left my house with the medicine, he went to one of the agents of the 'Medico-Botanic Club,' (a shoemaker), who attended; I did not see the woman again; but the husband told me that he had not given any of my medicine. The woman lived about eleven hours after I first saw her. In both these cases I refused a certificate of the cause of death. How easy will it be, with such a state of things, for parties tired of maintaining their relatives to rid themselves of the burden, and then urge as the plea that they did it all for the best! And do we not every day hear of parties being poisoned for a paltry burial fee of a few shillings? Does the law afford no remedy for such a state of things? To me there appears to be none; for if the medical attendant, who alone can know these things, interfere, he is compelled to attend to give evidence in a Court of Justice, where he must silently listen to any insult or insinuation the counsel may think proper to put upon him; and this is said to be done for the ends of justice; and yet, if he silently permits these things to be perpetrated, he undoubtedly incurs a serious responsibility. I am informed, that these people, in order, as they think, to evade the law, do not give the medicine with their own hands, but visit the patient, prescribe, and then tell the friends that they may give it or not, as they think proper. It would be well that both they and the friends should remember, that if they undertake the treatment of a dangerous disease, and are guilty of gross ignorance or neglect, they are both guilty of manslaughter. But if, after calling in a qualified practioner, they withhold from the patient the medicine prescribed, and substitute for it that of an ignorant person, it would, I think, justly become a question whether they had not been guilty of a still more serious crime."—We fear there is no law that will touch these Coffinites. Their name is expressive of their deeds, and it is a matter of great regret that there are so many persons ready to fall into the snares which quacks set for them. The poor and ignorant need protection, and the Government ought to use every means to prevent human life being sacrificed by quacks. We hope the new Medical Reform Bill will have a stringent clause against unlicensed practitioners.

A Young Subscriber" will find all the information he seeks in Mr. Quekett's excellent work on the Microscope.

Mr. J. H. Cooke, Shrewsbury," is thanked for his obliging offer, but the pamphlet has already been received and noticed in the columns of the "Medical Times."

Dr. Burton, of Walsall," recommends the following formula for diarrhœa, which he says has been universally successful in his hands during the last sixteen years.—℞ Tinct. opii.; acid. acet. dilut. (P. L.) aa., ℨij.; aquæ. distill., ℥viiss; M. sum. coch. mag. omni 2 vel 3 horâ; repetand. si urgeat diarrhœa.

Mr. E. M. D., Aires, Galway."—The papers will be continued till completed.

Scalpel."—It is one of those tricks by which some endeavour to get themselves into practice.

We are obliged to Mr. O'Neill for his communication.

Dr. Balfour" has our thanks; we will write to him privately.

Seneca."—Received.

Dr. Townsend."—Communication received.

ST. GEORGE'S HOSPITAL MEDICAL SCHOOL, LONDON.

The Session 1849-50 will Commence

on MONDAY, OCTOBER 1st, with an INTRODUCTORY ADDRESS, by Dr. BENCE JONES F.R.S., at Half-past One o'Clock.

DESCRIPTIVE and SURGICAL ANATOMY — Mr. PRESCOTT HEWITT and Mr. POLLOCK.
PHYSIOLOGY and GENERAL ANATOMY — Mr. ATHOL JOHNSON.
PRACTICAL ANATOMY — Mr. POLLOCK and Mr. ATHOL JOHNSON.
CHEMISTRY—Mr. NOAD and Dr. BENCE JONES, F.R.S.
PRACTICAL CHEMISTRY—Mr. NOAD.
MATERIA MEDICA—Dr. PITMAN.
MEDICINE—Dr. NAIRNE and Dr. PAGE.
SURGERY—Mr. TATUM.
MIDWIFERY—Dr. ROBERT LEE, F.R.S.
MEDICAL JURISPRUDENCE—Dr. FULLER and Mr. H. C. JOHNSON.
BOTANY—Mr. HENFREY, F.L.S.

Clinical Lectures on Medicine and Surgery are given by the Physicians and Surgeons of the Hospital during the Winter and Summer Sessions.

Some lectures on the application of Chemistry to the Diagnosis and Treatment of Disease will be given by Dr. BENCE JONES, F.R.S.

Practical Chemistry is taught in the Laboratory of the School.

Practical Pharmacy, under the superintendence of the Apothecary of the Hospital.

A Course of Lectures on MIDWIFERY will be given by DR. ROBERT LEE, F.R.S., during the Winter Session of 1849-50.

The SUMMER SESSION will COMMENCE MAY 1st.

SCHOLARSHIPS, PRIZES, &c.

At the end of the Summer Session, Examinations will be held for two Scholarships, of the value respectively of £40 and £20 per annum, each tenable for two years.

Examinations of all the classes for Prizes and Certificates of Merit also take place, and Prizes given by Sir Benjamin Brodie, Dr. Chambers, and Dr. Seymour, are awarded.

Some of the Lecturers and other gentlemen connected with the Hospital receive students to reside with them.

Further information may be obtained from any of the Lecturers; or from the Apothecary of the Hospital, who is authorized to enter the names of students.

ST. THOMAS'S MEDICAL SESSION.

The Introductory Address will

be delivered by Mr. SOLLY, on MONDAY, 1st of OCTOBER, 1849, at Eight o'clock p.m.

Gentlemen have the option of paying £40 for the first year, a similar sum for the second, and £10 for each succeeding year; or of making special entries to Lectures, or to Hospital Practice.

SCHOLARSHIPS AND PRIZES FOR 1849-50.

A SCHOLARSHIP of £20 for the best Voluntary Classical and Mathematical Examination, at the commencement of the Student's Hospital attendance.

TWO SCHOLARSHIPS, for first year's men, each of the value of £20 a year, and tenable for three years.

The TWO HOUSE-SURGEONS, the DRESSERS, and the RESIDENT ACCOUCHEUR, will be selected according to merit, and provided with rooms and commons in the Hospital, free of expense.

The PRESIDENT'S PRIZES: The first, 10 guineas the second, 5 guineas.

TWO PRIZES for CLINICAL MEDICINE, and PRIZES and CERTIFICATES of HONOUR, in each of the different Classes.

DR. ROOTS'S PRIZE: 10 guineas. One of the GOVERNORS, a PRIZE of 5 guineas.

The TREASURER'S PRIZES: The first, a Gold Medal. The second, 5 guineas.

The TREASURER'S PRIZE, to be awarded in 1851 £100 for the best Essay, including Original Researches on Organic Chemistry, in its relation to Pathology and Practical Medicine. The special subject of the Essay is, "On the Chemical and Physiological Action of Mercurial Preparations."

MEDICAL OFFICERS AND LECTURERS.

Dr. Roots, Consulting Physician; Dr. Barker, Dr. Leeson; Mr. Green, Mr. South, Mr. Mackmurdo, Dr. Goolden, Dr Risdon Bennett, Dr. Cohen, Mr. Solly, Mr. Le Gros Clark, Mr. Dixon, Mr. Simon, Dr. Waller, Dr. Gregory, Dr. E Meryon, Mr. Grainger, Mr. Saunders, Mr. Rainey, Mr. G. Luxford, and Mr. Adams.

COLLEGIATE ESTABLISHMENT.

Under the direction of the Treasurer and Almoners of the Hospital, houses have been fitted up as residences for the Students, and a College Hall, where commons will be provided.

To enter, or to obtain further information, apply to Mr Whitfield, Resident Medical Officer, at St. Thomas's Hospital.

Middlesex Hospital School of

MEDICINE. SESSION 1849-50.

HOSPITAL.

PHYSICIANS—Francis Hawkins, M.D.; Mervyn A. N. Crawford, M.D.; Seth Thompson, M.D.

PHYSICIAN-ACCOUCHEUR—Charles West, M.D.

ASSISTANT-PHYSICIAN.

Robert Gordon Latham, M.D., F.R.S.

SURGEONS—Mr. Alex. Shaw; Mr. Campbell De Morgan Mr. C. H. Moore.

ASSISTANT-SURGEON—Mr. Mitchell Henry.

SURGEON-DENTIST—Mr. Tomes.

APOTHECARY—Mr. Corfe.

The Hospital has recently been much enlarged, and important alterations and improvements have been introduced in its internal arrangements. It now receives 285 in-patients, and contains wards specially appropriated to the admission of cases of syphilis and of cancer, in the male and female, and of uterine disease. Number of out-patients, 9,316.

Clinical Clerks and Dressers are selected by the Physicians and Surgeons of the Hospital from the most deserving pupils without additional fee.

A Senior and Junior House-Surgeon are elected half-yearly from the Dressers, and are provided with board and residence in the Hospital, free of expense.

Clinical Lectures will be given during the Winter and Summer Sessions, and Clinical Prizes will be awarded for reports of cases.

Students who are desirous of entering to the Medical and Surgical Practice of the Hospital, apart from the Lectures, for the periods required by the College of Surgeons and Apothecaries' Company,—viz., eighteen months of Medical, and three years of Surgical Practice,—may do so by making one payment of £30.

Instruction in Practical Pharmacy, with opportunities of Dispensing, is given by the Apothecary.

LECTURES.

WINTER SESSION, commencing MONDAY, OCT. 1.
PRINCIPLES and PRACTICE of MEDICINE—MERVYN A. N. CRAWFORD, M.D., and SETH THOMPSON, M.D.
PRINCIPLES and PRACTICE of SURGERY — Mr. ALEXANDER SHAW.
PHYSIOLOGY and GENERAL ANATOMY—Mr. CAMPBELL DE MORGAN.
DESCRIPTIVE and SURGICAL ANATOMY — Mr. CHARLES H. MOORE.
PRACTICAL ANATOMY and DEMONSTRATIONS—Mr. THOMAS WILLIAM NUNN.
MORBID ANATOMY—Mr. MITCHELL HENRY.
CHEMISTRY—Mr. THOMAS TAYLOR and Mr. CHAS. HEISCH.

The Dissecting room is open Daily from Eight o'clock a.m. to Five o'clock p.m., and attendance is given for six hours daily.

SUMMER SESSION, Commencing MAY 1, 1850.
MIDWIFERY and DISEASES of WOMEN and CHILDREN—Mr. C. METCALF BABINGTON.
MATERIA MEDICA and THERAPEUTICS — A. P. STEWART, M.D.
FORENSIC MEDICINE — ROBERT GORDON LATHAM, M.D., F.R.S.
BOTANY—ROBERT BENTLEY, F.L.S.
MORBID ANATOMY—Mr. MITCHELL HENRY.
DEMONSTRATIVE ANATOMY—Mr. THOMAS WILLIAM NUNN.
PRACTICAL CHEMISTRY—Mr. THOMAS TAYLOR and Mr. CHARLES HEISCH.

All Students attending this Course will be required to pay an additional fee.

General Fee for attendance on the Hospital Practice and Lectures required by the College of Surgeons and Apothecaries' Company, £75.

This sum may be paid by instalments of £30 at the beginning of the first Session; £30 at the beginning of the second Session; and £15 at the beginning of the third Session.

Prospectuses and further information may be obtained on application to Mr. De Morgan, at the Hospital daily, from Twelve to Two; to any of the Lecturers; or to Mr. Corfe, the Apothecary, at the Hospital.

To Druggists and the Medical

PROFESSION.—W. and S. GAINES, late Dickson, Anderson, and Simmons, Seedsmen and Herbalists, Covent Garden Market, beg respectfully to offer Leeches, and all other articles of the best quality at the lowest prices.

*** Importers of Carrageen Moss.

Dr. Stevens' Saline Treatment

of CHOLERA.—Dr. Stevens having distinctly shown, in the "Medical Times" for September 1, No. 518, that under the pure and unmixed saline treatment as proposed by himself, the mortality in Cholera has been but 6 per cent., Mr. HOOPER begs to announce, that he has prepared the SALTS as recommended by Dr. Stevens, and that they are to be obtained, with full directions for use, by post or otherwise, at 7, Pall-mall East, and at 55, Grosvenor-street, London.

UNIVERSITY COLLEGE, LONDON.

FACULTY OF MEDICINE.

SESSION 1849-50.

THE CLASSES will COMMENCE on the 1st of OCTOBER,

when Professor WALSHE will deliver an INTRODUCTORY LECTURE, at Three o'Clock.

Classes in the order in which Lectures are delivered during the day:—

ANATOMY—PROFESSOR QUAIN and PROFESSOR ELLIS.
ANATOMY and PHYSIOLOGY—PROFESSOR SHARPEY, M.D.
CHEMISTRY—PROFESSOR GRAHAM.
COMPARATIVE ANATOMY—PROFESSOR GRANT, M.D.
SURGERY—PROFESSOR ARNOTT.
MIDWIFERY—PROFESSOR MURPHY, M.D.
MEDICINE—PROFESSOR WALSHE, M.D.
PRACTICAL ANATOMY.—The Pupils will be directed in their studies during several hours daily by PROFESSOR ELLIS and Mr. CADGE, Demonstrator.
ANALYTICAL CHEMISTRY.—PROFESSOR A. W. WILLIAMSON, Ph.D., 9 a.m., 4 p.m.

SUMMER TERM.

The following subjects will be taught during the Summer Term:—

BOTANY—DR. LINDLEY.
MIDWIFERY—DR. MURPHY.
PATHOLOGICAL ANATOMY—DR. JENNER.
COMPARATIVE ANATOMY and ZOOLOGY—DR. GRANT.
FORENSIC MEDICINE—DR. CARPENTER.
PRACTICAL CHEMISTRY—MR. WILLIAMSON.
MATERIA MEDICA—PROFESSORSHIP VACANT.

Hospital Practice daily throughout the year:—

PHYSICIANS—DR. WALSHE, DR. PARKES.
ASSISTANT PHYSICIAN—DR. GARROD.
OBSTETRIC PHYSICIAN—DR MURPHY.
SURGEONS—MR. ARNOTT, MR. QUAIN, MR. MORTON.
ASSISTANT-SURGEONS—MR. ERICHSEN, MR. MARSHALL.
DENTAL SURGEON—MR. DURANCE GEORGE.

Medical Clinical Lectures by Dr. Walshe, also by Dr. Parkes, Professor of Clinical Medicine, whose special duty it is to train the pupils in the practical study of disease at the bedsides during the visits, and also by a series of lessons and examinations on the physical phenomena and diagnosis of disease to classes consisting of a limited number, and meeting at separate hours.

Surgical Clinical Lectures, by Mr. Arnott, and specially by Mr. Quain.

Prospectuses may be obtained at the Office of the College.

Residence of Students.—Several of the Professors receive students to reside with them; and in the office of the College there is kept a register of parties unconnected with the College who receive boarders into their families; among these are several medical gentlemen. The register will afford information as to terms and other particulars.

At University Hall, an institution in the neighbourhood of the College, collegiate residence, under the superintendence of a Principal, is provided for a limited number of students.

WALTER H. WALSHE, M.D., Dean of the Faculty.
CHAS. C. ATKINSON, Secretary to the Council.

August, 1848.

The Lectures to the Classes of the Faculty of Arts commence on the 16th of October.
The Junior School opens on the 25th of September.

British Medical Agency, 52,

Regent-street, London, adjoining the County Fire and Life office.

To Surgeons and Chemists.—Gentlemen requiring the disposal or purchase of good and established practices and businesses, can readily effect the same by partnership or otherwise, by furnishing full and necessary particulars.

That qualified Visiting and Dispensing Assistants may always be immediately procured, or selected for Gentlemen residing at a distance from the metropolis, possessing not only professional attainments and abilities, but also assiduity, good moral character, manners, and address, and whose references have been subjected to the strictest investigation previous to registering their names.

To insure the immediate services of efficient and suitable assistants, and will also prevent the loss of time, trouble, and disappointment which has hitherto been attended with great personal inconvenience and expense to many of the profession, all communications to be made to Mr. Wilson, from Eleven to Five.

ORIGINAL LECTURES.

LECTURES

ON

THE CHEMISTRY OF THE POISONS;

OR, ON

PRACTICAL TOXICOLOGY.

SHOWING THE APPLICATIONS OF CHEMISTRY TO THE DISCOVERY OF CRIME.

By H. LETHEBY, M.B., Lond:
Lecturer on Chemistry at the Medical College of the London Hospital.

LECTURE VIII.

Impurities in commercial sulphuric acid.—(a) Compounds of nitrogen and oxygen.—(b) Sulphurous acid.—(c) Arsenious and arsenic acids.—(d) Sulphate of lead.—(e) Other saline impurities.—(f) Carbonaceous matter.—(g) Selenious acid—Sources of these impurities.—Dangers and disadvantages dependent on their presence.—Modes of recognising them, &c., &c.

Common oil of vitriol of English commerce is a very impure preparation; for it always contains one or more of the following substances:—namely, sulphurous acid, nitric acid, hypo-nitrous acid, deutoxide of nitrogen, sulphate of lead, lime, potash, soda or iron, organic matter and arsenic. And as you cannot ever venture to make use of such an impure liquid either for chemical or medico-legal researches, without seriously endangering the evidence which may be deduced therefrom, it is necessary that you should be acquainted, not only with the means of recognising these impurities, but also with the modes to be employed for the purpose of removing them from the liquid in question. I shall, therefore, occupy your attention during the present Lecture, in discussing this most important part of our subject.

IMPURITIES IN COMMERCIAL SULPHURIC ACID.

(a) *Compounds of Nitrogen and Oxygen.*—These compounds are nearly always present in crude sulphuric acid; and they owe their origin to one of two sources; they are either derived from the nitric acid, nitrous acid, and binoxide of nitrogen, which are employed as oxydising agents in the manufacture of oil of vitriol; or they are deduced from the aqua fortis which is so commonly made use of for the purpose of destroying the dark colour occasioned by organic matter in the acid. In both cases, however, the impurities are easily recognised by the following characters. When oil of vitriol contains a large amount of nitrous or hyponitrous acid, it effervesces upon the addition of a little water, and evolves red fumes, which have an acid pungent odour. I have of late found that many of the commercial samples of oil of vitriol exhibit this character; and I am led to think that such acids have been used in the rectification of nitric acid for the manufacture of gun cotton. When the vitriol contains a smaller proportion of these azotic compounds, it produces a dark reddish tint on adding it to a solution of proto-sulphate of iron or green vitriol. This tint varies from a light rose red up to a deep olive brown or black, according to the amount of azotic compound present; and the discoloration may be produced either by nitric acid, nitrous acid, hyponitrous acid, or even the deutoxide of nitrogen. If it be dependent on the first-named compound, the oil of vitriol will not affect the colour of a solution of bichromate of potash; but if it be due to the presence of a lower oxide of nitrogen, this solution will, upon adding it to sulphuric acid, acquire an emerald green colour, in consequence of the reduction of chromic acid and the formation of a green sesqui-salt of chromium. In order to demonstrate this fact, we will take a weak solution of bichromate of potash, and add it drop by drop to the impure acid: as you will here observe the yellow colour of the solution is instantly changed into a green one. Other oxydising agents may likewise be made use of for the purpose of recognising the presence of the lower oxides of nitrogen: for example, permanganate of potash, and deutosulphate of manganese are each robbed of their oxygen, and, consequently, decolorised when they are brought into contact with any of these impurities; or we may take advantage of a suggestion which has been thrown out by Professor Schönbein, and employ a few grains of sulphur as a means of exhibiting the presence of free nitric acid for, as this chemist has remarked, when nitric and sulphuric acids are mixed, the resulting compound nitro-sulphuric acid, has the power of oxydising sulphur and many other substances, with considerable energy. He says, in fact, that the mixture behaves towards these bodies as a kind of *aqua regia*, in which chlorine has been replaced by peroxide of hydrogen. In the course of his investigations, he found that nitro-sulphuric acid acts rapidly upon sulphur even at ordinary temperatures; and he states, that when flowers of sulphur are stirred into a fluid which contains only one drop of nitric acid in two ounces of pure oil of vitriol, a perceptible quantity of sulphurous acid is evolved,—a gas which may be recognised either by means of the starch and iodic acid test before mentioned, or by its decolorizing a piece of paper which has been made blue by iodide of potassium, starch, and an atmosphere of chlorine. This re-action, however, is not manifested when the acid solution is diluted with water before the introduction of the sulphur, and it is, therefore, not always applicable to the discovery of nitric acid.

As regards the delicacy of the green vitriol test, it may be said, that a solution of protosulphate of iron will determine the presence of the one-millionth part of any oxide of nitrogen; and, in order to witness its reactions, you are to operate in the following manner:—Take about one drachm and a half of strong sulphuric acid, mix it with about ten or fifteen drops of water, and let it cool; then add, drop by drop, about half a drachm of a saturated solution of protosulphate of iron, taking care that the temperature of the mixture does not rise to any great extent, and, as you will here remark, the colour of the liquid will change from a rose or violet red up to an olive or deep brown, according to the quantity of azotic compound present. In performing this test it is well to notice the colour of the ferruginous solution as it floats upon the heavier stratum of sulphuric acid, and to remark whether the colour is deepened at the moment of mixing the liquids.

If you were to inquire of me concerning the disadvantages which result from the presence of these nitrogenous impurities, I should have to tell you, that when sulphuric acid contains a rather large proportion of any compound of nitrogen, it is unsuited for the development of arseniuretted and sulphuretted hydrogen, two gases which are frequently employed in analytical research, for the oxygen of the impurity appropriates the hydrogen of these gases, and so prevents them from being evolved; but I cannot say that the presence of a small quantity of nitric acid is a matter of any great moment; in fact, I have been led to think that it is rather advantageous than otherwise, as it insures the oxidation of any sulphurous acid which may have remained in the liquor at the time of its manufacture.

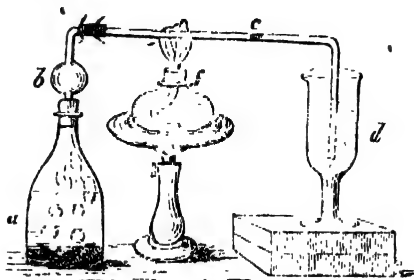
(b) *Sulphurous Acid* is another very common impurity in oil of vitriol; for, whether sulphuric acid be obtained by the combustion of sulphur, or by the distillation of green vitriol, this impurity is almost sure to be present in it, and, under such circumstances, the acid cannot be used in Marsh's apparatus without producing results which are very likely to baffle the skill of the unwary. In order to illustrate this I must anticipate our labours a little. When dilute sulphuric acid is poured upon granulated zinc, hydrogen gas is evolved, and, if arsenic be present in any of the materials used, the hydrogen so liberated will instantly seize on the elements of the poison and pass off as arseniuretted hydrogen, a compound which is usually recognised by the two following characters:—First, if it be passed through a solution of nitrate of silver, it renders the liquid dark and turbid; and, secondly, if it be heated as it traverses a tube of Berlin glass, it is decomposed, and deposits a bright ring of metallic arsenic. Now, these are the two characters which are commonly relied on as proofs of the existence of arsenic in one or other of the matters employed; but, as I will now proceed to show you, the presence of a little sulphurous acid in the oil of vitriol used in the experiments will give rise to somewhat similar looking results. I have here a dilute acid which contains a small quantity of the impurity in question, and although it is perfectly free from arsenic, yet, if I add it to a few pieces of granulated zinc, and transmit the gas so generated through a solution of nitrate of silver, it will instantly blacken the liquid, and produce an appearance which exactly resembles that witnessed in the former experiment. So, also, if it be heated as it traverses a glass tube, it will deposit a yellowish ring, which is very likely to perplex the judgment of the unskilful. The rationale of these actions is the following:—When hydrogen gas is liberated in a liquid containing sulphurous acid, the latter compound is decomposed, and its sulphur, by entering into union with the more powerful electro-positive element—hydrogen, forms sulphuretted hydrogen,—a gas which has the property of darkening the salts of silver, and of being decomposed when it is submitted to a red heat. Taking advantage of these re-actions, the chemist is enabled to discover with much certainty the existence of sulphurous acid in oil of vitriol; for if we add the impure liquid to a little zinc, and test the evolved gas by means of a piece of paper moistened with sugar of lead, we can instantly detect the merest trace of sulphuretted hydrogen, a compound which is never produced when both the acid and zinc are pure.

Again: the researches of Pelletier, Heintz, Girardin, Fordos, and Gelis, &c., have pointed out another mode whereby we may determine the presence of sulphurous acid in any acid mixture. Take about two or three drachms of the suspected liquid, add a few drops of water, and then about one drachm of an acid solution of proto-chloride of tin; immediately cover the glass containing the mixture with a piece of paper moistened at one spot with a solution of acetate of lead; allow the paper to remain in this state for ten or fifteen minutes, then examine it both by reflected and transmitted light, and observe if it be darkened at the spot where it was moistened with the lead solution,—if so, the liquid contains sulphurous acid. In order to explain the action of this test, I must refer to the investigations of Wackenroder; from which it appears, that an atom of sulphurous acid (SO^2), and one of chloride of tin ($Sn\ Cl$), are mutually decomposed, forming sulphuret of tin ($Sn\ S$), and an oxychloro-compound, which is of no importance to us. The sulphuret thus produced is not, however, a permanent compound; for it is rapidly decomposed by the free acid of the liquor, and converted into sulphuretted hydrogen, which escapes, and a salt of tin which remains in solution. In speaking of this test, Wackenroder says, that it is extremely delicate; and that by resorting to it, he has found that most of the better kinds of sulphuric acid exhibit traces of this impurity. It must be borne in mind, however, that all the other oxyacids of sulphur, excepting oil of vitriol, manifest the very same re-actions when they are treated in this manner.

(c). *Arsenious and Arsenic Acids.*—The presence of these acids in oil of vitriol is a matter of the most serious consequence to the medical jurist, inasmuch as he is accustomed to employ large portions of sulphuric acid in several of the processes now resorted to for the detection of arsenic in organic mixtures; and, as you will readily imagine, unless he can be quite certain that the acid made use of in the analysis is perfectly free from this poison, he can never place the slightest reliance upon the results of his operations, or even venture to deduce an opinion therefrom for the guidance of a magistrate or jury.

Now, as some of you may be questioned concerning the source of this poison, it is proper that I should direct your attention to the following facts.

Prior to the year 1838, manufacturers were accustomed to use Sicilian sulphur in the production of oil of vitriol, but during that year, in consequence of a monopoly, which was granted by the Sicilian Government to a French Company, for the preparation and sale of this article, foreign sulphur became



so dear that it could not be profitably employed for the purpose in question. Fortunately for all parties, the monopoly is now suppressed, but before this could be effected we were thrown, to a very great extent, upon the resources of our own country and iron pyrites, a mineral hitherto considered a an almost useless article, was suddenly called into requisition, and largely used for the manufacture of sulphuric acid. Since that period the employment of iron pyrites for this purpose has become almost universal, and the mineral is now largely obtained from the southern and south-eastern coasts of England, from the refuse heaps which have accumulated for centuries in the mining districts of Cornwall, and from the county of Wicklow and other places in Ireland. All these varieties of the mineral are more or less contaminated with arsenic; in fact, I have detected as much as 10 per cent. of metallic arsenic in many of the Cornish specimens, and, as this poison is volatilised, and undergoes combustion in the same way as sulphur during the manufacture of oil of vitriol, it is impossible to employ these minerals for such a purpose without having the acid highly charged with the poison in question. In one manufactory, which I had an opportunity of inspecting a few years since, I noticed that the bottom of the lead chamber was covered to a considerable depth with arsenical and orpimental mud, and I here show you a mass of crude arsenic, which was obtained from the chimney of a furnace in which copper and iron pyrites had been roasted. These, therefore, are the great sources of arsenic in oil of vitriol, and, as you may easily imagine, the proportion of the poison therein may often be very considerable. Mr. Scanlan asserted, at one of the meetings of the Pharmaceutical Society, held in the month of July, 1844, that he had procured as much as one grain and a half of sulphuret of arsenicum from 2,000 grains by measure of sulphuric acid. Dr. Rees has obtained between twenty-two and twenty-three grains of this poison from a pint of oil of vitriol; and Mr. Watts states, that the amount may even reach to thirty grains in the pint. M. Dupasquier, who has published a long paper in the *Journal de Pharmacie* on the contamination of oil of vitriol with arsenic, says, that although the amount of this impurity is subject to great variation, yet it may be estimated, on an average, at from one to one and a half parts in the 1000. In the course of some experiments which I have made from time to time on this subject, I have had an opportunity of verifying the results obtained by Dupasquier; for, at one period, viz., about five or six years ago, the sulphuric acid of commerce was generally highly charged with this impurity; in fact, it often contained as much as ·6 per cent of the metal. At the present time, however, it is rather an unusual occurrence to find even as much as ·2 per cent. of this poison in crude sulphuric acid; and this circumstance arises from the fact, that manufacturers are more careful in the choice of their pyrites. It is hoped, too, that they will, ere long, again resort to the practice of making the acid solely from Sicilian sulphur.

In directing your attention to the methods which must be employed for the purpose of recognising this very formidable impurity, I ought to mention, on the authority of Dupasquier, that the poison always exists in oil of vitriol in the state of arsenic acid. You may, therefore, proceed to recognise it in one of two ways.

1st. Neutralise the sulphuric acid with a solution of carbonate of potash, then slightly acidulate the liquor with a small portion of muriatic acid; filter it and submit it to the action of sulphuretted hydrogen gas. If arsenic be present, it will manifest itself in the form of a golden yellow precipitate, which is soluble in liquor ammoniæ.

2ndly. You may determine the presence of this impurity in another, and as I think, more conclusive manner. Take about three or four drachms of the crude acid; heat it with a couple of drops of concentrated nitric acid, and mix it with about ten or twelve parts of water, so that its specific gravity may be reduced to about 1100. Pour this mixture upon a drachm or so of granulated zinc, and transmit the gas thus generated through a solution of nitrate of silver. Should arsenic exist in the acid it will be made evident by the production of a black precipitate in the silver solution. You must not, however, lose sight of the fact, that sulphurous acid will occasion a similar looking precipitate. In order, therefore, to determine whether the re-action has been occasioned by arseniuretted or by sulphuretted hydrogen, it is necessary to transmit the gas through a red-hot tube of Berlin glass, and to notice the character of the sublimate; for, as I have already shown you, arseniuretted hydrogen produces bright steel-looking ring, while sulphuretted hydrogen thus treated occasions a deposit of yellowish white sulphur.

ARRANGEMENT OF THE APPARATUS FOR DETERMINING THE PRESENCE OF SULPHUROUS ACID AND ARSENIC IN OIL OF VITRIOL.

(a) A flask in which the zinc and acid are placed, for the generation of hydrogen. (b) A small bulb for retaining any of the acid liquor which may be carried over by the hydrogen. (c) A tube of Berlin glass, which conveys the hydrogen and its impurities into a solution of nitrate of silver (d). By means of the spirit lamp (f), the tube is made red-hot, and a sublimate is produced at the point (c).

(d) *Sulphate of Lead* is another very common impurity in oil of vitriol. It is also, like the preceding, a very momentous one; for, as we are accustomed to use large quantities of sulphuric acid in carbonising the tissues for the discovery of lead, it is of the greatest importance that the acid employed should be perfectly free from this poison. The impurity in question is derived from the lead chambers in which the acid is manufactured, and it is produced by the joint action of nitric and sulphuric acids upon the metallic walls of the principal condenser. Dr. Ure says, that commercial sulphuric acid often contains from 0·1 to 0·15 per cent. of sulphate of lead; he states, however, that the amount of the salt which oil of vitriol is capable of taking up is much more limited than is generally supposed; for, after adding a large portion of carbonate of lead to concentrated sulphuric acid, and allowing the mixture to stand in a warm place for twenty-four hours, he found that it contained only 0·5 per cent. of sulphate of lead. In the course of my own experiments I have submitted six samples of oil of vitriol to analysis, and I have discovered that they may contain from 0·032 to ·08 per cent. of this salt, a quantity which is considerably below the amount mentioned by Dr. Ure, and I apprehend, therefore, that greater precautions are now used in the manufacture of sulphuric acid.

In order to recognise the presence of this impurity, you have but to dilute the acid with ten or twelve parts of water, and notice whether the liquid acquires a milky appearance, for this happens when salt of lead is present, and, on allowing the mixture to stand, it deposits a white precipitate of the insoluble sulphate. To prove, however, that this precipitate is a lead salt, you are to collect it on a filter, and then, while it is still moist, diffuse it through a solution of hydrosulphuret of ammonia, by which means the white salt, if it contain lead, will be instantly converted into a black one; or you may demonstrate the presence of lead in the precipitate in another way:—Take it from the filter, mix with about twice its bulk of carbonate of soda, and heat it upon a piece of charcoal before the blow-pipe. In this way the lead will be reduced, and will appear as minute globules upon the surface of the charcoal. Lastly, there is a third method, by which lead may be recognised in this precipitate:—Remove it from the filter and boil it for an hour or so with a solution of carbonate of soda; let the liquor stand for a few minutes, and then pour off the supernatant fluid, add a little acetic acid to the undissolved residue, and test it for lead with iodide of potassium and sulphuretted hydrogen; the former of these re-agents should give a yellow precipitate, and the latter a black one.

(e). *Other saline impurities* of less importance than the preceding are frequently contained in crude sulphuric acid; for example, according to Dr. Ure, this acid often contains from 0·4 to 0·6 per cent. of alkaline sulphates—salts which are in many cases derived from the nitre, &c., employed in the manufacture of the acid. Occasionally, however, saline matters are introduced into weak oil of vitriol for the purpose of increasing its specific gravity, and so making it appear to be a more concentrated liquid than it really is. Judging from the experiments which were made some time since by Dr. Ure, it appears that every one part of sulphate of potash added to 100 of oil of vitriol, increases its density by about 6 parts in the 1000; so that a crude acid, which contains only about 74·5 per cent. of real acid, will have its specific gravity raised from about 1820 to 1853 by the addition of 3·3 per cent. of sulphate of potash. It is evident, therefore, that the addition of a few grains of sulphate of potash to a very weak oil of vitriol is sufficient, were we to depend on its density alone, to make it appear as an acid of most enormous strength. Fortunately, however, for the consumers of such acids, the sophistication is easily recognized, for they have but to evaporate a given portion of the liquid to dryness, and weigh the saline residue.

(f). *Carbonaceous matter in oil of vitriol* is known by its communicating a dark colour to the acid; and although this impurity is not of much moment on its own account, yet it merits attention by reason of the fact that it always indicates the presence of sulphurous acid, a compound which is very perplexing to the medical jurist.

(g). Lastly, some chemists have spoken of the existence of *selenious acid* in oil of vitriol; and notwithstanding that I cannot show you a specimen of sulphuric acid so contaminated, yet I am inclined to think that the impurity is not a very uncommon one, for I have frequently noticed in the zinc cells of my galvanic batteries, a red deposit which I cannot satisfactorily account for; and I regret that I have not made a careful inquiry into the nature of his deposit. It might have been selenium reduced by the nascent hydrogen in the cell; and, if so, the presence of such a substance in any liquid used in Marsh's apparatus would be very likely to lead to embarrassment and difficulty; for the characters manifested by seleniuretted hydrogen are very analogous to those produced by its compeer, arseniuretted hydrogen. In fact, they both burn with a whitish opaque flame, and deposit similar-looking sublimates when the combustion is effected in a glass tube. They both blacken a solution of nitrate of silver, and are decomposed, giving rise to a metallic ring when they are passed through a red hot glass tube. There are, however, two characters by which seleniuretted hydrogen may be instantly recognised. First, the gas itself has a most intolerable odour, and it produces great irritation of the eyes, nose, and air passages. Berzelius states, that in the first experiments which he made upon this gas, he let up into his nostrils a bubble about the size of a pea. "It deprived me," said that chemist, "so completely of the sense of smell, that I could apply a bottle of concentrated ammonia to my nose without perceiving any odour. After five or six hours I began to recover the sense of smell, but a severe catarrh remained for about fifteen days." On another occasion, a little of the gas accidentally escaped; it produced a sharp sensation in the nose, red eyes, and a dry and painful cough, at length succeeded by expectoration, tasting like the vapour from a boiling solution of corrosive

sublimate. "These symptoms were removed by a blister to my chest. The quantity of seleniuretted hydrogen gas which, on each of those occasions, entered into my organs of respiration, was much smaller than would have been required of any other inorganic substance whatever to produce similar effects."—(Brande.) This character, therefore, is quite sufficient of itself to discover the presence of selenium. But seleniuretted hydrogen manifests another property which is even more marked than the preceding; for, when the gas is burnt in a glass tube, after the manner frequently recommended for the combustion of arseniuretted hydrogen, it produces a powerful and highly offensive odour, which has been compared to putrid horse-radish.

As to the source of this impurity, selenium is not by any means an uncommon constituent of iron pyrites, the mineral so often employed in the manufacture of oil of vitriol. Berzelius discovered it in great quantity in the mundic of Fahlun. It is also a constituent of the pyrites found in the Isle of Anglesey; and I doubt not that it may be a component of the sulphurets obtained from Ireland, Cornwall, and other places.

With this I conclude my remarks on the impurities of oil of vitriol; and in my next lecture I shall pass on to consider the modes in which sulphuric acid is to be deprived of these contaminating agents.

THE LUMLEIAN LECTURES,

DELIVERED AT THE ROYAL COLLEGE OF PHYSICIANS.

By R. B. TODD, M.D.,
Fellow and Censor of the Royal College of Physicians.

Reported expressly for this Journal.

LECTURE I.

ON CONVULSIVE AFFECTIONS—CHOREA—TETANUS—EPILEPSY.

Mr. President,—In every branch of science which depends on the observations of years and of ages, it is of importance that its cultivators should review the state of knowledge, and inquire whether the foundation be secure, or whether any change ought to be made in the superstructure, to supply the defects which previous ages have left. With this view, I have chosen for the subject of these lectures, the pathology of those diseases of muscular action of which convulsions is a prominent symptom. Under the general term convulsions, I include all those irregular motions, or sets of motions, which are not under the control of the will, and which are for the most part kept up by physical or mental excitement; if the flexors of a limb are thrown into an action of this sort, I should say they are convulsed. There are three kinds of convulsions:—

1. Jactating, or choreic.
2. Tonic, or tetanic.
3. Chronic, or epileptic.

1. This class is peculiar from the jerking motions it gives rise to,—irregular, uncontrollable by the will. Here, there is no augmentation of power, but great debility, sometimes preceded by a paralytic state. A very remarkable feature in this class is, that it is influenced by that state of the nervous system which produces sleep; choreic convulsions cease immediately under the influence of sleep, and re-appear on waking.

2. The tonic is a state of greatly increased muscular tension; a muscle thus convulsed may be compared to the string of a violoncello, screwed up to its highest pitch; there is here a great increase of muscular force, so that sometimes the fibres become ruptured. Cases of this kind may be exactly imitated by passing the galvanic current through the spinal cord.

3. The chronic class consists of powerful contractions of sets of muscles, each act of contraction being rapidly succeeded by one of extension, and so on, till the force is worn out. The powers of their contraction is very great, and though this is not favourable to the rupture of the fibres, yet bones are often broken in such paroxysms. I shall now enumerate various forms of the disease accompanied by these manifestations.

In the first class, the typical malady is chorea; in the second, the type is tetanus, the clinical history of which is well known; and along with this may be classed those diseases peculiar to children—croup and laryngismus; I place epilepsy as the type of the third, and, along with it, convulsive fits of chorea.

1. Chorea. This disease is one peculiar to early life; it very rarely occurs after the age of puberty, or, if it does, it is where the signs of that state are not well developed. The period of life in which chorea generally takes place is that between 6 and 15. Of the 189 cases observed in the Childrens' Hospital of Paris, 10 only occurred before 6 years of age; 179 between 6 and 15; and, of the latter, 118 between 10 and 15. It affects girls in a much greater proportion than boys. The examination of its phenomena shows two varieties.

1. General, which may be either acute or chronic.
2. Partial.

1. In this, the patient is unable to walk, and the speech becomes affected; no voluntary action can be performed; there is protrusion of the tongue, and one wonders how it escapes being injured by the teeth. The patient is obliged to remain in bed, rolling incessantly, so that the friction causes troublesome sores; and sometimes they literally shake themselves to death. When such is the case, it is of the acute form; but happily this is rare, and general chorea occurs more frequently in a chronic form, with longer intervals of sleep.

2. But the most common form is that where it is only partial; and I will just point you to the phenomena of these cases.

(1.) The affection is not symmetrical. One side is more affected than the other. In general, this difference remains with that side, but, in rare instances, there is a disposition to shift—a tendency which is a common feature of gout. The affection of the tongue is also most characteristic and peculiar; the patient protrudes the tongue with remarkable force, and its subsequent retraction is as peculiar,—it is drawn back very slowly and with great caution. Sometimes this is the precursor of other choreic symptoms, and I have, from this feature, often been able to predict them. When choreic convulsion has affected one side, paralysis often affects the same side. In a few, paralysis precedes choreic convulsions, and is distinguishable by the sign of the tongue. The heart is very frequently affected in morbid chorea, and this is evidenced by its sound; a bellows-sound is often present. What, then, is the cause of this, is it occasioned by morbid deposits on the mitral valves? or does it depend on the anæmic state of the patient? The closure of the mitral valves is an effect of the accumulation of fluids in the ventricles, and this will be produced, no matter what the nature of the fluids may be. A watery state of the blood, of itself, cannot produce this sound; it is plain, then, that it must be caused by a disturbance in the action of the mitral valves. What, then, produces this disturbance? Is it owing to the muscular action of the heart? I apprehend not; and it appears to me that this sound is due to organic lesion, which prevents the closure of the mitral valves. Then, what creates this state of those valves? The answer to this inquiry is, that many of the patients are rheumatic; some experience endocarditis, which affects the mitral valves; many, also, are found to have articular pains and to experience deranged secretions. I have known many children in this state pass urine of a very high specific gravity. Choreic patients, also, often suffer from rheumatic fever. To give an instance of the connexion between chorea and rheumatic fever: One patient had good health till his eighth year; he then had an attack of rheumatism; in four months this was followed by chorea, of which he was cured, but had a second attack the year after; from this he recovered and remained well four years, then had another attack of rheumatism, and, in six weeks, a third attack of chorea. Chorea does not occur in the healthy, but among those, generally, whose digestive powers are feeble, and especially among the children of the poorer classes. Its tendency is to recovery. Of the 14,725 deaths registered in the quarter ending Christmas, 1848, only one is attributed to chorea, and this is the average of the same period for six years, with one curious exception, when six deaths were ascribed to it; and when we reflect upon the number of these cases that are neglected, we say, the natural tendency of the disease is to recovery; at any rate, it is not such a complaint as does not admit of cure. Of the few *post mortem* examinations that have been made, they show that chorea leaves behind it no traces of any lesion in any part of the body which was likely to produce it; and neither can it be supposed that opacity in the arachnoid or irritated ovaries should have any relation to it. The peculiar movements of chorea may occur in the rheumatic or gouty states. Sometimes the patient finds it impossible to accomplish certain actions. There is one curious affection which I should notice, the prominent feature of which is the inability to hold a pen, and to write for any length of time; after a person has written a certain number of words, the hand becomes spasmodically extended, and the pen drops; and yet all other actions can be well performed. No doubt the impairment of speech is of this character. Allied to this, also, are the fidgets of children; the child becomes miserable, and a misery to those about it; incessantly making grimaces, handling or touching everything with which it comes in contact. Children thus affected may be easily thrown into convulsions.

The second class is typified by tetanus. The points marked here are:—

1. Little variation of the symptoms in different cases; the varieties being only as to degree; in all there are rigid limbs and locked-jaw.

2. They occur without any observable lesion; and, what is more remarkable, artificial tetanus occurs without any lesion of the cerebral cord; there is no indication of a deranged structure.

3. It often appears endemically. It takes place in some localities more than in others; and is more common in the West Indies than in more moderate climates. In this country several cases are known to have occurred in some particular locality.

The tendency in tetanus is—death by exhaustion; in consequence of the violent paroxysms the respiratory functions become seriously impeded. The most auspicious sign is the prolongation of the intervals between paroxysms. The disease, called trismus nascentium, is due to a state of the system developed under deleterious local influences. Dr. Clarke, of Dublin, by means of improved ventilation, reduced it from 17 to 5 or 6 per cent. I have classed with these, that disease of infants known as laryngismus, because there are in it many points of resemblance to tetanus. These features are:—

1. Laryngeal spasms are truly tetanic, occurring in paroxysms, and lasting for a considerable period.

2. As in tetanus, it is brought on by sudden stimuli.

3. Tetanus sometimes does not extend beyond the muscles of the jaw and throat; but in laryngismus it extends to other parts, producing a similar condition of the head and feet. With these symptoms, there is often conjoined opisthotonos; during the paroxysm the child's consciousness is unaffected.

4. Laryngismus does not manifest itself in the robust, but in those of a weakly constitution and depraved nutrition. A strong, healthy, well-fed child never shows it.

5. Under the continued operation of the exciting cause of the disease, laryngismus exhibits a fatal result, and death takes place from rapid asphyxia; in such cases, the mode of death is exactly as in tetanus.

But in the third class of cases, the epileptiform convulsions are superadded to the tetanic.

The clinical history of some more formidable varieties may here be noticed; as, for instance, where the type of the malady is epilepsy. This is characterised by attacks of loss of consciousness, and last for a longer or a shorter interval. These cases are often accompanied by a loss of volition and

of locomotive power, which continues for some time, with a state of insensibility; and the patient remains in a profound sleep after the affection has left him; sometimes, indeed, it is so profound, that he is unconscious of having had a fit. The phenomena preceding the attack differs infinitely; some times there is a disturbed state of the intellect headache, or giddiness; sometimes the hearing is affected, or tingling in the ear, or the sense of smell is disturbed. One patient of my own had warning five minutes before, by being seized with violent tremor; and Dr. Gregory had a case in which the warning given was the phantom of a little old woman in a red cloak, striking him on the head. Sometimes delirium is the preceding symptom; he the patients become raving mad; and the knowledge of this fact once saved me from what otherwise might have been of extreme inconvenience. In most cases all the voluntary muscles are engaged while in some this affection is altogether limited to one side. The action of the heart is very much accelerated, and continues so for a long period. A dilated condition of the pupil is also observable. Epilepsy is a disease common to all periods of life; it may even occur *in utero*. There is an acute form as well as a chronic. In the chronic form, we remark that curious kind of periodicity which regulates it—occurring once in twenty-four or forty eight hours, or once a week; and although in this it exhibits some analogy to ague, yet it wants its precision. Of the hereditary character of the malady there can be no doubt. Epilepsy seldom kills; the patients die nominally of other diseases; diarrhœa disposes of vast numbers, while others pass into a state of dementia, and become insane. The earliest destructive indication is in the weakening of the perceptive powers; in this way only can we explain the fact, that the power of the memory in respect to recent occurrences suffers first. This failure takes place more rapidly as the paroxysms occur seldom or frequently. A very remarkable feature of this disease is, that sometimes the tendency to epilepsy ceases apparently of its own accord, without the possibility of assigning any reason for it. Epilepsy and insanity frequently go together; in other cases insanity precedes it; and in a third class the patients are insane only for a short time before or after the epileptic attack. Another most interesting point is, that his disease may go on for a considerable time without any apparent change in the condition of the brain. The congestion in the brain of the epileptic, and which is but seldom present, is attributable entirely to impeded respiration; and the bloody points found in the veins on dividing the hemispheres, the opaque arachnoids, and the adherent dura mater, are often found where there has been no epilepsy. These morbid appearances are constant, but the paroxysms are temporary; and, therefore, I think it impossible to attribute those appearances to that particular affection. As to whether hypertrophy of the brain may cause epilepsy, I must refer you to my next lecture.

MEDICAL SCHOOLS AND UNIVERSITY TOWNS OF GERMANY.

By DR. BUSHNAN.

(Continued from page 177.)

ERLANGEN.

Before continuing my account of the Medical Schools and University Towns of Germany, let me acknowledge the great assistance I have received in their compilation from my friend, Mr. Whitling, of Nuremberg. Without the aid of that gentleman, I could scarcely have obtained the great mass of information, upon the subject which I have laid, and have still to lay, before the Profession. I may further state, I am informed, that so much interest has been excited, even in Germany, by this series of Papers, that an edition in the German language is in the course of preparation.

About ten miles from Nuremberg, on the line of railroad between that city and Bamberg, lies the neat little town of Erlangen, containing the chief Protestant School of Bavaria, and its smallest University. It was founded by Frederick, Margrave of Bayreuth, in 1743, but subsequently underwent many changes, both in its direction and government. After the death of the last Margrave, in 1791 it fell to the lot of Prussia; in 1806, it was occupied by the French; and in 1810, the principality of Bayreuth, with the University of Erlangen, was finally conferred by Napoleon on the late Maximilian Joseph the First, under whose heirs it has remained. How long it may remain so is, however, uncertain, since, amidst other and manifold changes now in progress in Germany, a large portion of the kingdom of Bavaria, viz., Franconia in which this University is situated, is threatening a separation from the House of Wittelsbach in the event of its present representative rejecting the proposal for German unity under the King of Prussia. *Quem Deus vult perdere prius dementat*—and the princes of this country, in opposing the wishes of their people, are madly rushing on inevitable destruction. The reign of Absolutism is at an end and all the gods of Germany can re-establish it no more.

Erlangen, although the least of the Bavarian Universities is not destitute of Medical renown and the names of Schreger, Schelling, Karless Schubert, Rudolph, Wagner, Heyfelder, &c., are sufficient to enable it to maintain a respectable position, whether present or retrospective.

The number of students is somewhat under 400 of whom about 45 are destined for the Medical Profession. But the Medical Institutions here although sufficient for their objects, and, indeed fully equal to any demand that can be made upon them, are, nevertheless, not large; and, therefore do not afford that scope for study and improvement so amply found in the larger Universities. The number of Professors in the Medical Faculty is only eight. The Hospital, where are read the Medical and Surgical Clinics, contains about twenty rooms, of which two are appropriated to ophthalmic patients. The Medical Clinic is held from 10 till 11 o'clock every morning, by Professor Canstatt, a skilful man and good lecturer, and the average annual number of patients is about 2,200.

Connected with the General Clinic is the Polyclinic, in which the patients, though expected to present themselves at the lectures, are, nevertheless, partly visited at their own abodes. This seems occasionally to offer good opportunities to the young student for the study of many interesting cases, inasmuch as by the printed report now before us, it appears that the number of patients in the twelve months ending October, 1847, amounted to no less than 1,700,—very considerable for this little town, and the natural result of the great extent of poverty in and about Erlangen. Dr. Canstatt is the Professor of Medicine, and his assistant-physician, Dr. Winterich.

The Surgical Clinic, under the direction of Professor Heyfelder, is excellently arranged; it offers about 900 cases yearly, and from 80 to 100 serious operations. The Professor allows certain of the minor operations to be performed by the younger students under his immediate direction. The Lecture or Clinic is delivered at eleven in the morning, and lasts an hour. The cost of each of the above is 12 florins (1*l.* sterling) per semester.

The School of Anatomy, formerly an Orangery of the ancient Margrave's, is a spacious amphitheatrical building, well lighted, and containing various good-sized rooms, in one of which is the collection of anatomical preparations. During the winter semester, lectures are delivered here by Dr. Fleischmann and Dr. Herz, who give practical instruction, demonstrations, &c., during the summer, at a cost of twenty-two florins. The surgical operations upon the bodies are, however, directed by Professor Heyfelder, the terms for which, per semester, inclusive of subjects which are supplied from the Hospital and poor-houses, are twenty-eight florins. Lectures on Anatomy, Physiology, and Comparative Anatomy, are also given here, at a trifling charge, by Professor Will.

The Lying-in-Hospital is situated a little distance from the town on the Nuremberg-road. This Institution was formerly connected with the Surgical Clinic; but about twenty years ago the present building was thus appropriated, and it is under the able management of Dr. Rosshirt. The number of patients yearly admitted is about 250, and the entire arrangement is as good as circumstances admit.

Near the School of Anatomy is the botanical garden. It comprises a large and very valuable collection of plants, shrubs, and trees, both native and foreign. Well arranged and neatly kept, it reflects much credit on Professor Koch, to whose charge it is confided. In some rooms of the old palace there is a good museum of zoology and mineralogy, wherein are found numerous and well preserved specimens of the animal and mineral kingdom. These departments are under the care of Professors Will and Raumer. The collections are open to the public on Wednesdays and Saturdays, from one to three o'clock, p.m.

The curators deliver lectures, both in the Museum and at their own houses, at twelve florins per course.

In Chemistry, Professor Kassner is the teacher, and has the direction of the chemical laboratory, as well as of the physical institute. He does not, however, seem to be much in repute, as his style is said not to be clear, and his system imperfect. The students' complaint of him, translated into English, stands thus—" He is too clever to be understood; very ingenious, but not intelligible."

The University Library, like the Cabinet of Natural History, stands in part of the ancient palace. It is very extensive, and was greatly augmented in 1809, when the Altdorf University was suppressed, and its contents transported hither. These, amongst other valuable works, comprised a large Medical library, (Altdorf having also had its medical school), and an immense collection of original letters and MSS. of the most renowned physicians of the sixteenth and seventeeth centuries.

Connected with the Library is a Reading-room, where newspapers, periodicals, and the most interesting medical *brochures* are to be met with. This and the Library are opened every day, except Saturday, from one to two o'clock, and access, under certain regulations, can also be readily obtained at other times.

Professor Martius has an extensive and very interesting private collection of pharmaceutical preparations, containing between 2,000 and 3,000 specimens, of which the students have the use when attending his most instructive lectures.

Native students, who offer themselves for the doctor's degree, must undergo a severe examination on the following subjects:—

Surgery and Surgical Operations; Anatomy, simple and comparative; General Physiology; Special Pathology; Natural Philosophy; Pharmacology, &c., &c.

This done, they must propose a thesis and defend it publicly—oftentimes in Latin. If satisfactory, the diploma is granted. The amount of the various fees is 250 florins, (20*l.* 16s. 8d.) There are especial regulations for foreigners wishing to obtain the degree of Doctor of Medicine at this University. Those affecting English practitioners are as follows:—

Medical gentlemen having finished their studies, *but not yet authorised to practise* through the necessary examinations of their own country, are required to appear personally, for the purpose of undergoing an examination. Testimonials of their studies and moral qualifications are to be produced at the same time.

Gentlemen *already licensed to practise* are not exempted from personal attendance, *unless they have been already ten years in practice*, or are distinguished as medical writers, or otherwise by their reputation, public recognition, &c. With the exception of such cases, personal attendance is only dispensed with, when the applicant can prove by testimonials, that he has been ten years in practice, after having been legally authorized; that he is

of general and medical respectability; that he is prevented from appearing personally by private practice, public duties. &c. &c.

The Medical Faculty of Erlangen considers as legally authorised to practice :—

1. The Members of the Royal College of Surgeons in London, Edinburgh, and Dublin; or Members and Licentiates of any other Medical Board, entitled to grant licenses.

2. Medical gentlemen attached to public Institutions, as lecturers, physicians, or surgeons.

3. Medical gentlemen having appointments in the army or navy.

4. Medical gentlemen having been licensed to General Practice before the year 1815; that is, before the Act of Parliament conferring the Rights and Charter of the Apothecaries' Company.

5. Licentiates of the Apothecaries' Company are to be admitted only in case of their being able to prove, by testimonials, that they have been in extensive practice during a period of time that may be deemed satisfactory, or that they are attached to public Institutions.

A candidate for the Medical Degree is, moreover, required, to present a copy of one or more of his publications, should he be an Author. If this be not the case, he must submit a medical treatise in manuscript; this should be in Latin. Further, he is required to answer those written questions which the faculty think proper to propound in cases of absence; and to certify and solemnly affirm, at the end of the medical treatise and replies, *that he, and he alone, is the Author of them.*

Upon the satisfactory fulfilment of the foregoing regulations and payment of the fees, amounting in this case to about 300fl. or 25*l.* sterling, the diploma is granted.

Of German diplomas generally, thus much may be asserted; that they are, *for the most part*, easily obtained by foreigners—payment of the fees being too often regarded as the main proofs of qualification. The various examinations which the German student has to sustain, though far less *practical* than with ourselves, are, nevertheless, very severe; and, at the *Staat's Examen*, many and many a man who has passed the others in a creditable style, and thought himself secure is rejected, and at a comparatively late period of life, finds himself compelled to resign his hopes, and seek another occupation. The regulations ostensibly imposed upon the foreigner are, however, by no means insurmountable; indeed, we possess evidence enough to show that they are being every day evaded. (a)

A student at Erlangen—if of moderate habits—may live very inexpensively. He may obtain a good lodging for thirty florins per semester, or about 6*l.* per annum; and he may subscribe for his dinner at about sixpence per diem. There is not much society in the town, but the surrounding country (b) is attractive; the public gardens (particularly the Welt Garden) pleasant, and the general life agreeable enough.

As in most German towns, so at Erlangen, there is a good "Harmonie," in which many concerts and balls are given during the winter season; and the facility with which the student, by means of the railroad, can visit Nuremberg, Bamberg, and other interesting places, contributes greatly to his recreation and enjoyment.

The town, altogether, may be said to be distinguished for many things that render it an agreeable place of abode; for its learning also and education; for its various Institutions and liberal University. But, alas! how slow and unwilling some appear to listen to the voice of justice and even humanity, to say nothing of the higher claims of religious obligation! Thus, up to within the last few months, no Jew has been allowed to reside, *or even to sleep*, in the Protestant university town of Erlangen; and, although with a niggardly caution, which shows how hardly ancient prejudices are overcome, permission has been granted for Jews to live there, the advantage of dwelling within its limits seems to have been considered almost too great for the sons of Abraham, according to the flesh, to aspire to; therefore, ere the privilege can be obtained, the proposed inhabitant must *give proof of possessing property to the amount of* 20,000 *florins, and purchase a house in which to dwell.* And this is the equality of German Liberals in 1849! this the even-handed justice of German Protestant Christians in an university town!! Alas, for the poor Jewish people! Except, perhaps, the flying-fish, no race existing on the earth, in the earth, neither in the waters, have been the objects of so much unremitting, general, and relentless persecution as they.

With respect to student life generally, materials would have been afforded for a highly interesting volume, had each separate section of it kept a credible notary, who, in an entertaining manner, though, at the same time, adhering strictly to truth, had written down its respective history for the information and amusement of future generations. Erlangen would have deserved such a chronicler; for, though founded at a comparatively late period, and thus presenting none of those more striking peculiarities observable in other Universities, yet student life, with all its oddities and attributes, was there quickly installed, and among these sons of the muses found fitting representatives. A short notice of some of their doings, as gathered from certain old books and MSS., in the library referred to in this article, may not, perhaps, be uninteresting to a portion of our readers.

It is certain the particular element which exhibited itself so remarkably in the German students of the 19th century, and made them differ so pointedly from every other class, lay long hidden under a variety of forms, movements, and ceremonies; many of them of a far deeper and more solemn import than might at first be imagined. The Erlangen student, breaking through the custom of pigtails, bagwigs, and courtly dresses, sallied forth in stiff military jackboots, doeskin trowsers, heavy uniform coat, his hands gloved, and the thick tilting gauntlet thrust into the iron-basket hilt of the victorious *schlaeger*, which hung at his side, as well pleased with himself as any hero of the olden time. In these days, learning was principally laid on the shelves of the Professors, and few besides those who were really obliged to do so, troubled themselves to bring it down. All who did, were termed "bread hunters," meaning such as studied for bread. These, however, seem to have taken it pretty coolly, for the examinations were not nearly so severe as at present, and *to have been a student*, and *to have studied*, appear, at that time, to have been looked upon, by most people, as one and the same thing. The Professor talked till he was hoarse amidst clouds of tobacco smoke, which, like heathenish incense, sent up its fuming wreaths to the already blackened ceiling of the Auditorium, while his disciples, instead of listening to him, were busy in arranging a sledging party, a duel, a "commerce," or some other matter of equal interest and importance. If the neglected Professor ventured to complain, or, as they term it, "shrug his shoulders," at their want of attention, his windows were broken the same evening. Formerly, if two of the students quarrelled, a circle was instantly formed in the market square, the military, citizens, peasants, and policemen assembling at pleasure to see the fun. The combatants stepped into the circle, and the blades were crossed. Such encounters were, however, at no time dangerous; and the pro-rector himself was often seen with his long pipe looking quietly out of window at what was going on. It was reserved for more modern duellists to fight with pistol and *stoss-rapier* (small sword), about which so many complaints are now-a-days made. The students agreed very well with the citizens, soldiers, and policemen, as long as the latter did nothing against what they termed Academic-Freedom. But as this peculiar branch of the family was found to be a lady of no ordinary and troublesome pretensions, the attachment of the students towards her did not always prove sufficient to keep off the unhallowed attempts of the other parties to bring her down a little; and the consequences were, sometimes, not only broken heads, but wounds of a more serious character, and, indeed, loss of life has now and then been known to occur. The citizens seem formerly to have had a great fondness for this kind of pastime, and, upon the slightest provocation, would turn out in battle array against the academicians, each party being armed with thick heavy sticks. The *fracas* would last for hours, till at length, losing all patience, the burgomaster would call out a troop of cavalry, which, dashing in amongst the belligerent parties, quickly dispersed them. On one of these occasions, some of the Erlangen Professors lent their aid and authority in quelling a riot in which the students were manifestly to blame. They were instantly marked men. Their lectures were abandoned. The students withdrew to Bayersdorf and the neighbouring villages, and sent word to those Professors, that "if they thought it necessary to continue to read lectures for their own amusement, it was all well and good, but if necessary for the edification of the students, they must come out to Bayersdorf, where they would be found assembled in the woods!" The pocket is always a dangerous casuist, and that of the Professors being as empty as their *auditorium*, they were obliged to give way, and publish a general amnesty ere their disciples would return.

The altercations of the Erlangeners with the Polizes Diener Police, were the most amusing. The latter had a mortal aversion to the term, "Schnurren," (Catchpole,) which the students applied to them pretty freely, running past the watchhouse, and crying, "Schnurren 'raus," (catchpoles come out.) The police soon made their appearance, and pursued the fugitives, who drew them by degrees into the dark, narrow streets, where thick ropes, that had been previously drawn across, caused many a scarlet feathered cap to roll in the dust, and its owner into the kennel.

These, and such like tricks, together with lamp breaking, changing the various tradespeoples' signs, and occasional processions, of a character either serious or grotesque, made up the sum total of their pastimes. Times, however, have now changed, and the different features of student life, as well as their pursuits and pleasures, are changing too; nor is it improbable, that, in a very few years, all the present distinctive characteristics of that class, both in dress and deportment, will have passed away, and become, what some of them already are, matters of entertaining history.

(a) Perhaps some idea of the real value attached to such diplomas, *generally*, by those German Universities which grant them, may be gathered from the significant fact, that in no case have we been able to get at the names of those Englishmen who have obtained them. All applications, whether *direct*, or made through some of the resident Professors with whom we are acquainted at several of the principal Universities, have alike failed—"*It is against their rule to make the names public.*" Had any honour been likely to accrue, either to the buyers or sellers of these dainty devices, there is no doubt that the Faculties from which they emanate would be ready enough to make known the names of the distinguished physicians upon whom they have been conferred.

(b) It is not far from the beautiful Muzzendorf district, and its enchanting valleys. See "Pictures of the Capital and Valleys of Franconia." By H. J. Whitling. Publishing by Bentley.

ON SCARLATINA.

By J. W. TRIPE, M.D., M.R.C.S., and L.A.C., London.

(Concluded from page 197.)

Professor Paget, in his admirable lectures on "Nutrition," &c., delivered at the College of Surgeons, observes, that the precision with which the nutritive processes are performed is so great, that the newly formed blood and tissues take the likeness of the old ones in all their peculiarities. In proof of this he adduces, that not only does the individual retain the form and expression of his features, but he retains even his peculiar temperament; also, that an injury inflicted on a part is perpetuated;

thus, the scar resulting from a wound will, if occurring in a child, grow with the child's growth and be preserved throughout life. There is, however, a tendency in all diseased and altered tissues to revert to their original condition, so that a scar may wear out. Mr. Paget then proceeds to say "What we see in scars or thickenings of parts appears to be only an example of a very large class of cases; for the exactness by which the process of assimilation in a part maintains the change once produced by disease, offers a reasonable explanation of the fact, that certain diseases only occur once in the same body. The poison of small-pox, or of scarlet fever, for example, being once inserted, soon, by its multiplication or otherwise, affects the whole of the blood, alters its former composition; then the disease, in a definite form and order, pursues its course, and finally the blood recovers, to all appearance, its former state. Yet it is not what it was; for now the same material, the same variolous poison, will not produce the same effect upon it and the alteration thus made in the blood or the tissues is made once for all; for, commonly, through all after life, assimilation never deviates from the altered type, but reproduces particles exactly like those altered by the disease; the new ones, therefore, like the old, are incapable of alteration by the same poison, and the individual is safe from the danger of infection."—Lecture III.

Mr. Paget adduces another very strong proof of the exactness of the assimilative process, that I am tempted to quote it, and this not only as a very apt one for my purpose, but because it explains better than any passage of similar length, the mode in which the recollection of events long past are impressed on the brain, and by which the immaterial mind takes cognizance of them. "It is asked, How can you suppose the brain to be the organ of memory, when you suppose its substance to be ever changing? or, how is it that your assumed nutritive change of all the particles of the brain is not as destructive of all memory and knowledge of sensuous things, as the sudden destruction by some great injury is? The answer is, because of the exactness of assimilation; the impression once made upon the brain, whether in perception or intellectual act, is fixed and there retained; because the part, be it what it may, which has been thereby changed, is exactly represented by the part which, in the course of nutrition, succeeds to it. Thus, in the recollection of sensuous things, the mind refers to a brain, in which are retained the effects, or rather the likeness, of changes that past impressions and intellectual acts had made." The law of tendency to revert to the former condition, may obliterate the impressions, when "the mind—itself in its own immortal nature unchanged, and immutable by anything of earth—no longer finds in the brain any traces of the past." These extracts from Mr. Paget's lectures put in a very satisfactory point of view this most important part of the process of assimilation, and satisfactorily show how the change once effected in the blood, remains permanent for the remaining period of our existence.

In a previous part of this memoir, I quoted a paragraph from Dr. Bateman's work on cutaneous diseases, to show that he had frequently observed severe affections of the throat to occur in persons who had previously had scarlet fever. The inflammations of the tonsils, and of the adjacent parts are stated to have attacked the patients only during the prevalence of an epidemic of this disease, and to have pursued in every respect the course of the scarlatinoid cynanche. The description given by Fothergill and Huxham of the malignant sore throat is so characteristic of that produced by the scarlet fever poison, that but little doubt remains concerning the true cause of this disease. I have myself seen several striking instances of this kind during the last epidemic; in three cases of scarlatinoid cynanche the patients had had scarlatina simplex previously, and in two others the same occurred, but as they were attended with other peculiarities, the cases, although previously related, will be again noticed. A son of Mrs. M. was attacked with scarlatina maligna-gravior, and died. Mrs. M., who had scarlatina simplex in early life, was seized four days after the eruption appeared on her child, with a severe form of cynanche, with the peculiar aphthous-like ulceration of the mucous membrane of the fauces so common in scarlet fever. When she was recovering, her two daughters were brought home from boarding-school, and the elder one, who had also had scarlatina sine anginâ at a previous period, contracted a sore throat precisely resembling that of the mother; she recovered. The younger daughter, who had not had scarlet fever, had an attack of the malignant kind and died. The son was attacked on June the 11th and died on the 14th the mother became ill on the 16th, the eldest daughter on the 2nd of July, and the younger daughter on the 11th.

These cases lead to the following conclusions that, the alteration of the blood is not, alone, a sufficient protection against a subsequent attack, but that an affection of all the tissues liable to the disease is also necessary. Lastly, that a person who has once had the disease may propagate it in a subsequent attack, even although he may not, during the second attack, have any disease of the skin.

That the alteration in the blood is not alone a sufficient protection against a second attack, is evidenced by these and similar cases, in which severe scarlatinoid cynanche happened in those who had had scarlatina simplex (sine anginâ) previously.

We can scarcely doubt that, as far as the blood will admit of it, the alterations usually effected by the passage of the virus into the system take place as fully during the progress of scarlatina simplex as of scarlatina gravior or maligna; inasmuch as it is not likely that the poison would stop short of changing all the particles then in the blood, which were capable of undergoing this change, any more than a ferment introduced into a saccharine solution would—other circumstances being favourable—cease converting the sugar into simpler compounds.

The opinion of all those who have sufficiently considered this matter is favourable to the supposition that the whole mass of the blood is changed by one attack. Mr. Paget states, "So it must be, I think, with all the diseases which, as a rule, attack the body only once. The most remarkable instance, perhaps, is that of the vaccine virus. Inserted *once*, in almost infinitely small quantity; yet, by multiplying itself, or otherwise affecting *all* the blood, it may alter it once for all."*—Lecture III. We may, then, consider that the blood is, as far as it will at that time admit of it, altered entirely by the attack, and that all the material capable of taking on the fermentation, or other process, when the virus of scarlatina is absorbed into the system, is changed in the first attack, whether that be one of scarlatina simplex, mitior, or gravior. But although we admit that this alteration in the blood is full effected, yet we must not overlook the tendency existing in the blood, as well as in all other living parts, to revert, when altered by disease, to their normal state; and that, therefore, in a few instances the blood may be capable a second time of allowing this process to take place.

Admitting, then, that the blood is fully altered by one attack, how is it that a person may have a second attack? It must either be in consequence of the blood having returned to its original condition, or by so large an amount of the poison having been absorbed as to attack a tissue that had formerly been spared. It may be asked, what proof is there of this? I answer, the experience of all physicians, that scarlatinoid cynanche is most prevalent when scarlatina rages in an epidemic form; the fact that a person having the scarlatinoid cynanche may transmit either the same form of the disease, or the scarlet fever itself, to another. This latter is fully shown in the cases of Mrs. M. and her eldest daughter. We here had an instance of the mother, after exposure to the infection of scarlet fever, contracting the cynanche, and infecting a daughter with the same, who in her turn infected a sister with scarlet fever of a fatal type. The dates of the death of the child, and of the attacks of the mother and of her daughters, forbid any other interpretation being put on the facts.

Although I am willing to admit the priority of the changes in the blood, yet I think it impossible, if poisonous materials which have been introduced into the circulation have certain "seats of election," and a greater affinity for one or more organs than for others; that the organs or tissues with which the poison combines, or through which it is cast out of the system, can escape being more or less altered. For instance, it does not seem probable that the poison of scarlet fever can be thrown out of the body by the skin, or by the mucous membranes of the alimentary canal or of the kidneys, or by all, without effecting some change in the tissues. If, then, we allow that this change takes place, is it not in accordance with the ordinary phenomena of the assimilative process, that this alteration would be perpetuated? Under these circumstances, if the poison was again introduced into the blood, would it not be more likely to attack a tissue for which it has an affinity, and which had not been thus altered, rather than one which had been? I think it is; and, therefore, consider, that an affection of all the membranes susceptible of the action of the scarlatina virus, is necessary for the perfect protection of the individual against a second attack. As some further proof of this position may be mentioned the fact so well known, that persons affected with the disease invariable become worse after the parts adjacent to the throat have become affected. What says Dr. Watson on this subject? "It is the condition of the throat that gives rise, in these cases, to the most formidable symptoms. The system is re-inoculated from that source."—Vol. II., p. 758. I am of the same opinion, and think that the action between the poison in the blood and the membrane diseased, gives rise to the formation of an increased quantity of the virus; and that an increase of the poison might thus occur, totally independent of any augmentation in the blood. If this be the fact, we can readily account for a person propagating the disease during a second attack, even although the blood may be incapable of allowing of any multiplication of the poison, or the skin may escape being in any way affected.

There is one point of the disease that has been incidentally mentioned, that requires a little fuller consideration. I allude to the greater affection of the throat in one person, and of the skin in another. This peculiarity has been well known for many years. Dr. Heberden (Comment. P. 28) states, "Even in the same family, when a number of children have been ill either together or immediately after one another, some have had the distinguishing symptoms of scarlet fever, and others of the malignant sore throat." Dr. Blackburne (on Scarlet Fever, pp. 48-49) observes, "It most frequently happens, that the guttural is the primary affection, and the efflorescence a symptom which appears after the constitution is universally impregnated, only in certain skins disposed to receive it."

How can we explain this? This may readily be done by variations in the "power of election" possessed by the tissues for substances circulating in the blood. Thus, in one individual the tissue of his skin may have a greater affinity for the virus of scarlatina, than those of the throat or kidneys, and *vice versa*. Under these circumstances, if the material in the blood by means of which the poison is enabled to multiply, should exist but in a small quantity, the amount of poison so formed would be would be proportionably small, and the disease would appear in that structure for which the poison had the greatest affinity to the complete or partial exclusion of the other parts.

We have an instance of the same material attacking different parts of the same tissue at different times, in what have been termed by Dr. Budd and Mr. Paget symmetrical diseases. The morbid material here seizes upon corresponding parts of the two extremities or sides of the body, in preference to any other parts. Mr. Paget observes, in regard to this, "How, or in what, the part of a tissue differs from another, I cannot tell; but some of these may not be even permanent, but may depend on different parts of a limb

* The italics are my own.

being in different stages of development or degeneration. The symmetrical parts of the tissues being in this respect exactly alike, may be equally and simultaneously affected with the disease, whilst other parts of the same membrane may be unaffected, until in the course of time, they attain by degeneration or development the very same condition as the parts first affected. Then, if the morbid material still remain in the blood, the parts also become diseased."—*Lecture the First.*

In addition to the influence exerted by individual peculiarities in predisposing to a concentration of the poison to one membrane rather than to another variations in what has been termed the constitution of the atmosphere tend to the same result, so that in one epidemic we find severe affections of the throat to be very common, whilst in another we find them very rare; and, again, in another epidemic, we constantly meet with dropsical symptoms and disease of the kidneys, whilst in another they are very rare.

I would observe, in conclusion, that my design originally was, as stated at first, to have sketched only the peculiarities of the last epidemic; but finding that this could not be done without treating of scarlet fever in general, I was induced to extend the memoir to its present length. This has unavoidably led to some fundamental errors in the arrangement; for instance, the subject of morbid poisons, which forms the conclusion, should have been the introductory part; the consideration of the poison of scarlatina, and of the causes modifying it, should have constituted the first instead of the second part; and the pathology and symptoms of the disease, its complication and *sequelæ*, ought to have formed the conclusion instead of the commencement.

Commercial-road, April, 1849.

PROGRESS OF MEDICAL SCIENCE.

FRANCE.

[From our own Correspondent.]

CHOLERA.

We have little new to remark with respect to the progress of cholera here. Many begin to despair of seeing the malady take its departure, and endeavour to accustom themselves to the idea of domestication; but, of this latter there can be little danger. The average mortality in the hospitals remains perfectly stationary, as does also that of the cases admitted; the latter being from 24 to 25 daily: the former from 14 to 15. It seems strange, that at this, the last period of the epidemic, the proportion of deaths to cases should still exceed 50 per cent. Even in the military hospitals, which have received only 34 cholera cases from the 1st to the 15th of this month, 16 soldiers died. In the city hospitals 542 patients were admitted with the disease during the same period, and of these 316 died. The difference is so light as to be easily accounted for by the difference of physical condition between the two classes of patients.

From the provinces we continue to receive deplorable accounts, not only of the ravages committed by the epidemic, but of the panic excited amongst the ignorant part of the population. In many localities fear seems to have banished every remnant of civilised feeling. The sick are abandoned without succour, and the military are compelled to bury the dead. Nor is the state of things confined exclusively to the rural districts. At Toulon the soldiers have been converted into grave-diggers, and a private letter from Marseilles gives the following account of matters in that city:—

"The cholera and the panic consequent to its appearance make rapid progress at Marseilles. On Sunday, September 9th, we had 60 deaths from cholera, amongst which, 10 of the military in town, and 10 in the outskirts. On the 8th, we counted twenty-eight shops closed in the Rue de la Canebriere, and the placards on them showed that the proprietors had absconded through fear. The Corporation now met, and declared its meetings permanent, in order to organise efficient aid. Six additional medical posts were opened, and the members present subscribed 3,600 francs to commence with."

It would hardly be believed, that in one of the principal cities of France no precautionary measures had been taken until the mortality reached sixty a day. But they do not now, as in Sterne's time "order these matters better in France."

Indeed the same want of foresight appears to have existed in relation to the sanitary state of the army at Rome. You know with what fatal effect malaria emanates from the Pontine marshes during the summer months, and that a residence in Rome during the sickly season is barely supportable even by those hardened to the climate. The French soldiers have been suffering cruelly from marsh fever, yet little or no preparations were made for an eventuality which everybody foresaw. Not only medical assistance, but the commonest remedies were wanting. This neglect, and an unusually unhealthy season have given rise to serious mortality amongst the conquerors of Rome, and rendered it necessary to send off a member of the Board of Health, with a host of physicians and apothecaries in his train. They started on Saturday last.

In the meantime His Holiness, the Pope, gives "plenary indulgence" to all French soldiers who may die in the Holy City; but this touching proof of gratitude does not diminish the mortality, and seems to be lightly appreciated by the "infidel Gaul." Indeed, I heard one of these unbelievers—a dragoon—assert, that the army would have been much better pleased had His Holiness distributed a '*petit verre*' of brandy to each man instead of a 'plenary indulgence." There is no accounting for tastes.

Apropos of military surgery, considerable sensation has been excited here by a most unfortunate exposure, which recalls to mind the corrupt practices that prevailed under the late dynasty. A staff surgeon of the first-class, occupying a high post in the Council of Revision, has been condemned to one year's imprisonment for having corruptly exempted several conscripts from service. He had made a lucrative affair of it for a long time, but was caught at last.

"Raro antecedentem scelestum
Deseruit pede, pœna, claudo."

As a kind of set-off against the above, I may mention, that M. Gaultier de Claubrey, member of the Academy of Medicine, and M. Dupins, an old military surgeon, have been raised to the rank of officers of the Legion of Honour. The red ribbon and the rosette are becoming almost as common as in the good old times.

The Garden of Plants received last week some rare specimens of Egyptian natural history from Clot-Bey. A new variety of rattle snake is one of the most remarkable objects.

It seems strange that the principle of a sanatorium could never take root in London, whereas it flourishes here, and has been found productive of great public benefit. The cause probably lies in the difference of habits between the two people. Besides the immense number of private "*maisons de santé*," we have a national sanatorium in the Faubourg St. Denis, capable of receiving 160 to 200 patients, who are lodged and treated in the very best manner for two, three, or four shillings a-week, according to the accommodation. Government is about to form two more establishments of the same kind, one in the Faubourg St. Germain, the other in the Chaussée d'Antin. It is a pity that the system of leaving everything to private enterprize should be pushed so far in England as to prevent our authorities from assisting similar undertakings.

A new species of bougie and catheter, made of gutta percha, has been recently introduced here, and highly spoken of by the hospital surgeons. It is probable, however, that the article is merely an importation from England.

The meeting of the Academy of Sciences on the 8th did not give birth to anything of importance in a medical way. M. Pellarin read a paper on the causes of cholera, and, like a pure chemist, asked whether it should be attributed to sulphuretted hydrogen or to ammoniacal gas? He inclines to think the latter. This is cutting the knot in a very simple manner.

M. Pasteur read a memoir on racemic acid, and the two acids of which it is composed, one causing polarised light to deviate to the right, the other to the left. It is, however, a curious fact, that racemic acid appears to have ceased to exist; at least its discoverer, M. Kestner, can neither find it in the products of his manufactory, nor reproduce it artificially.

NEURALGIA AND ITS TREATMENT.

Neuralgic affections appear to become more frequent every day, and to attack a much greater proportion of males than formerly. The older Practitioners were wont to regard this peculiar class of diseases as being confined to the branches of the fifth pair of nerves; but we now know that many other nervous branches are liable to this affection; and last year, M. Valleix broached for the first time, I believe, the doctrine of "general neuralgia," as distinguished from local.

A well-marked case of this "general" neuralgia recently occurred in the wards of M. Valleix at the Hôtel Dieu. It was characterised by severe neuralgic pain in almost every part of the body. The pains appeared to radiate chiefly from the spinal marrow as a centre; and not only the points of exit, but the parts supplied by the posterior column of the spinal marrow were sensitive in the highest degree. The pains likewise existed at various points of the exit of the fifth pair. There was no febrile excitement, and the pulse never rose beyond 120. The pains of the extremities were accompanied by a kind of trembling, somewhat analogous to that of delirium tremens. On the other hand, the case presented some appearances of a cerebral affection; but the differences from both were too well marked to admit of any doubt.

M. Valleix proposes etherizing the patient, and then applying transcurrent cauterization along the whole spinal column, a mode of treatment which has long been the hobby of the worthy Professor.

CHLOROFORM IN NEURALGIA.

In the above, however, we have a much less severe, and if we are to believe Dr. Delaroque, of the Necker, a more efficacious remedy against all kinds of neuralgic pains. Dr. Delaroque has been trying chloroform topically, and the result of his experiments is, that chloroform is 'the specific for pain." He relates several cases, from which I select the following:—A young woman laboured under hysteric cephalagia of a very severe form, and generally supervening on the cessation of the catamenia. Thirty drops of chloroform were dropped on a piece of cotton, and the latter passed lightly two or three times over the forehead. On each application the patient experienced a pricking sensation in the skin, and the headache was, for the moment, dissipated. Dr. Delaroque then held the cotton under the nose of the patient, who fell off at once into a gentle sleep for a few minutes. On awaking she was perfectly free from headache, and the author informs us that she has not heard of a relapse.

The second case was one of torticolis, accompanied by serve pain from contraction of the muscle, which often drew the head nearly down to the shoulder. The disease attacked a young person, twenty years of age, after suppression of transpiration. Slight friction, with the chloroform and cotton, was tried, as in the former case. The spasmodic pains ceased immediately. The same effect followed every successive application, and the patient recovered.

The third case related by Dr. Delaroque was one of syphilitic cephalalgia, which had obstinately resisted every attempt made, not only to cure, but to relieve the affection. Frictions with the cotton produced some alleviation, and when the chloroform was respired through the nose, the headache disappeared altogether. It was, of course, thought expedient to follow up the improvement by an antisyphilitic treatment.

While on this subject, I may allude to an interesting and rather warm debate which took place at the last meeting of the Academy of Medicine, on

chloroform and its effects. The debate was produced by a paper of the newly-elected member, and as it is an established usage in the Academy, as well as in our own Institutions at home, to snub the juniors, so M. Robert received many hard knocks; but he returned them with interest, and, to me, seemed to have by far the best of the argument.

Several fatal cases from the employment of chloroform have recently occurred here, and many others have reached us from foreign countries. It is also undeniable that we cannot tell beforehand what the effect of the application on the individual may be. As a few grains of calomel or opium will salivate or narcotise certain individuals, so a small dose of chloroform occasionally serves to develope fatal accidents in certain constitutions. Setting out from these premises, M. Robert asks, "Are there any premonitory symptoms which may serve as a guide, and warn us not to proceed any further with the administration of the remedy?" He has remarked, as indeed every other physician must have done, that in many cases the early symptoms of etherization are accompanied by excessive agitation, precipitous respiration, and disturbance of the motor function, nearly amounting to convulsions. In 120 cases where he had employed chloroform, he had met with three cases of this kind, and it was on this point that he wished to fix the attention of the Academy. The symptoms did not seem to depend on the dose of the chloroform, but on the individuality of the patient. Hence, M. Robert concludes, that when such symptoms appear, they are a warning to the medical man not to proceed any further.

M. Velpeau, who descended from the Presidential chair to answer M. Robert, made a long discourse in favour of chloroform; but I confess myself unable to guess the conclusion at which he desired to arrive. He did not deny that the use of chloroform was occasionally dangerous; but, on the other hand, he refused to admit as proven that *any* of the deaths mentioned were really occasioned by that substance. In one of the cases, death was instantaneous; and it was impossible to believe that the remedy had proved fatal, before it was respired. In fact, MM. Velpeau and Roux seemed to argue that chloroform could never be fatal, because it had never produced fatal consequences in their hands. M. Roux likewise adverted to the mode of administering chloroform which is often employed, but which he denounced as faulty in the extreme. It is absolutely necessary to have an apparatus with which the air may penetrate to the lungs at the same time as the vapour. If this be attended to, he had not much apprehension of any unpleasant or dangerous effects.

These arguments leave the objections of M. Robert entirely untouched, and it is probable that prudent operators will prefer attending to his advice rather than incur the risk of despatching their patients through ill placed confidence.

GERMANY.

[From our Berlin Correspondent.]

Since cholera has prevailed in Berlin, that is, from the end of May to the present time, the number of persons attacked has amounted to 4500, out of which, about 3000 have fallen victims to the malady. At present, the daily returns of cases average 30, denoting a decrease in the intensity of the disease, and affording a hope, that we may soon be relieved *in toto* from the scourge.

A member of the Medical Council, Dr. Schutz, has lately issued a publication, founded on official data, and giving a view of the five outbreaks of the epidemic which have visited Berlin. The first four took place in the years 1831, 1832, 1837, and 1845. The result of his observations show, that the proportion of cures to the proportion of deaths (2 to 3) has always been the same; that certain quarters and streets suffered more than others, especially the middle of the town, which is surrounded by the ancient fortress dyke, and contains narrow and densely populated streets; and that the contiguity to water seems innocuous, provided it be not stagnant.

I acquainted you, some time back, that associations had been formed among the working people of Berlin to insure medical aid. In some districts of the town tradespeople also follow the example. The following rules are observed. The members choose a Managing Council, who receive the contributions and elect a medical man, who must reside in the same quarter of the town. Every single person contributes one-sixth of a dollar—sixpence,—and every family one-third of a dollar—one shilling a year; this entitles them to medical advice and medicines; and demonstrates, in a small way, with what zeal the principles of association are carried out.

It is reported, that an alteration is to take place in the mode of granting medical diplomas. They are to be accorded at a more moderate cost; but the aspirants are previously, instead of subsequently, to be subjected to the Staats Prüfung, or Government examination. Until now, the doctor's degree cost 30 Friederichs d'or, and was utterly useless, since, although possessing one, no one was allowed to practise without undergoing the State-examination, and possessing, in addition, the Government authority.

This day (the 14th September) is the eightieth anniversary of the birth of Alexander Von Humboldt. Permit me, therefore, to bring to your recollection the great naturalist, who, no doubt, has many friends and admirers among your readers. Notwithstanding his varied and active career, and his many wanderings in the course of his long and chequered life, his mind has retained the freshness of its youth, and his body its activity and strength. To speak here of his scientific merits would be superfluous; they are engraved on the memory of all; but I may add, that his character as a citizen is not inferior to his reputation as a philosopher. No one knows better than Humboldt, how to foster and encourage talent; and Germany has to thank him for having raised from obscurity many of her most eminent scientific men.

From Austria we receive the melancholy tidings of the death of one to whom the Medical Profession there is much indebted, viz., Baron de Feuchtersleben. In 1848, when Germany was cradled in the sweet dream of emancipation from ancient error, and indulging in the fond hope of breaking the rusty and time-worn chains of custom, Feuchtersleben was named Secretary to the Board of Public Instruction. In this situation he sought, with untired devotion, to bring about the regeneration of his much loved Fatherland. But the political convulsions of the country interfered with his plans, and prevented all his endeavours to re-organise the system of education. Reports say, that this noble and much-loved man died of grief for the present melancholy state of his native land. (a)

(a) [We have much pleasure in stating, that one of Feuchtersleben's most popular and interesting works - his "*Diætetik der Seele*," of which five editions have been published in Germany—is now passing through the Press in an English dress, and under the editorship of Dr. Bushnan.—Ed. *Med. Times*.]

Sanitary State of the Tower.—In consequence of the recent deaths amongst the troops quartered in the Tower from cholera, and the sickness of many, His Grace the Duke of Wellington, the constable of the fortress, has ordered, that the strictest inquiry should be made by the Medical department as to the general sanitary state of the barracks, the sewerage, and cleanliness, but particularly the quality of the water consumed by the garrison and inhabitants, which has, for a considerable time, been very much complained of. Although the ditches that surround the Tower have been dried up, and many other great improvements made, especially the spacious new barracks, there is one most important article of salubrity wanting—a pure supply of water, there being no wells in the fortress, and the spring-water has for years been procured by the troops from the pump in Postern-row, Tower-hill. There are near 3,000 inhabitants in the Tower, including the garrison.

Complaints having reached us of the irregular delivery of the Medical Times *in the country by the Booksellers and Newsmen, we state, for the information of our readers, that this Journal is always published early on Friday afternoon, so that it may reach the Provinces by post on Saturday morning.*

Correspondents are requested to address their Communications to "The Editor of the Medical Times *147, Strand."*

TO SUBSCRIBERS.

THE MEDICAL TIMES.

SATURDAY, SEPTEMBER 22, 1849.

Design and wisdom are impressed upon all the operations of Nature. The contemplation of the phenomena throughout the moral and physical world, forcibly illustrates the fact. "Partial evil is universal good." The poet, in few words, has embodied a just and important axiom. But, while it is at once accepted, it is seldom brought home to the heart, or appreciated by the understanding, in all its comprehensive truthfulness. It is pregnant with thought, and rich in practical application.

Man owes his existence, the development and the conservation of his powers, to the temporary evils to which he is subject. Life is one vast and ever-varying series of changes, and is surrounded by agents equally fitful in their condition and action. Both are in incessant motion, giving and receiving the elements of vitality. The uninterrupted interchange between them is a wide field, the cultivation of which falls within the domain of physiology and natural philosophy. The former, in association with chemistry, explains, with considerable accuracy, the nature of the organic operations of the animal system, specifies the different constituents which enter into the constitution of living matter; the latter treats of more general causes, on which animal and vegetable life depend; and, on its cessation, they continue to act, facilitating the process of decomposition, and, at the same moment, appropriate the materials, thus liberated, to fresh combinations. Among these general causes are the gaseous principles of the atmosphere, and its condition with respect to temperature, moisture, and weight, all of which admit of precise valuation. There is still one other agent which plays an important part throughout the universe, viz., Electricity, to which we have not adverted; and it is probably the great cause, on the modifications in the distribution of which all changes in the world without us are to be traced.

In regard to it, however, our knowledge is imperfect. We may collect it, analyse the effects it produces, and lay down the laws of its action; but of the function which it performs in relation to all matter, inert as well as organic, and especially in relation to ourselves

as animated beings, we comparatively know nothing. It will not be doubted, that almost all substances *obviously* possess it, and it will be as little questioned, from its known laws, that its quantity, consequently its influence in reference to these substances, is not fixed but ever fluctuating.

The deductions we might suggest from this fact, in illustration of our subject, and particularly in its bearing on the present awful Epidemic, are such as spontaneously arise from the foregoing train of thought.

As all matter abounds in electricity, and as it is evolved in all the changes of animal and vegetable life, as well as in the silent but magnificent operations of nature, carried on throughout the ample surface of the earth, and the equally extended world of waters, the amount at any one time existing in the earth and the air we breathe, will clearly be liable to great modifications. A familiar exemplification of this truth, is the occurrence of thunder and lightning after long-continued heat, the effect of which has been the accelerated operations to which we allude, uninterrupted in their course, until the balance of the vivifying agents of the atmosphere is disturbed,—Nature gives evidence of disorder, and expresses it in the sublimity of the convulsed elements.

These are temporary changes. May it not, however, occasionally happen from causes which it is impossible to define or even speculate upon, that the natural electric conditions of the earth or the air, may be somewhat permanently modified to an extent prejudicial to animal and vegetable life? Supposing such to take place, it is evident that new relations would be established between the electric fluid and the animal economy, the nature of which might be a deficiency in the usual proportion of this principle. No argument is required to prove that the electricity we possess is necessarily in general equilibrium with all objects around us, subject only to such differences as may possibly arise from local circumstances.

Agreeably to this view, Cholera may be referred to the altered electric conditions of the atmosphere. New susceptibilities of the animal system are created,—a predisposition to a particular species of derangement.

That state of the vital powers in which such predisposition originates, may be regarded as pervading more or less society at large, modified in its susceptibility to disturbance, by a variety of circumstances, such as the inherent tone or energy of the animal system, the habits of the individual, his mode of living, the character of a variety of influences to which he may be exposed, as well as the nature of the district in which he resides, as far as it is affected by the qualities of soil, and the manufacturing and other operations carried on. All such causes are to be considered, in taking an extended or philosophical view of the subject. According to the hypothesis here proposed,—which, whether true or false, would refer the predisposition primarily to the existence of peculiar electric conditions,—there is comparatively little difficulty in offering a rational explanation of the occurrence of this appalling Epidemic. Two things only are necessary for its production,—*the susceptibility, and a cause sufficient to disturb the balance of the vital powers.* The former, while it originates in the particular cause assigned, may, nevertheless, be aggravated to an extraordinary extent by the whole class of those agents or circumstances which are usually designated predisposing; and when brought to an exceedingly exquisite point, several of the same predisposing causes will at once be converted into the exciting, and give rise to this disease.

Why, then, should we believe that a mysterious agent or principle is in any way concerned in the effect? One general cause of the susceptibility exists, and if this be developed in an exquisite degree by any of the circumstances specified or implied, the slightest imaginable cause, whether internal or external, will at once excite the formidable symptoms.

There are many considerations, did our space permit us to pass them under review, that might be shown to strengthen this train of reasoning. The prevalence of diarrhœa, affecting more or less all classes of society, might be wielded with no less plausibility than power, in support of the above conclusions. Such a symptom is a direct illustration of the peculiar susceptibility of the nervous system to derangement; and in what manner does this arise, except from the modified electric conditions of the objects around us? It is clear that it cannot be ascribed to any property or influence excited by the ingesta, though these, under existing circumstances, may become exciting causes. For an efficient cause, we must look to something far more general,—a something which operates with different degrees of force on society at large; and what is so probable *as the altered electric conditions of the earth or air?*

We are aware that very grave objections may be urged against these views. It may be contended that a cause so general ought to produce far greater effects on both the animal and vegetable kingdom, than fall under notice. But in answer to this we might suggest, that the susceptibility, both in the animal and the vegetable, may depend not only on peculiar combinations of matter, but that the susceptibility which would otherwise arise, is kept in abeyance, especially in the animal, by a variety of circumstances unfavourable to its development, which the want of space will not permit us to particularize. But, after all, these remarks are merely suggestive,—thrown out for the consideration of our readers. We may, however, soon again revert to a subject so full of interest.

THE EVILS OF ENGLAND.—POOR-LAW MEDICAL RELIEF.

"A FAIR day's wage for a fair day's work," is the prayer of the industrious poor, the war-cry of the heartless professional agitator, and the hope of the sanguine theorist. That it is all these sufficiently indicates, that average industry and capacity will not always insure an average subsistence.

But if fluctuations of commercial prosperity, or those changes of different callings which are inseparable from the progress of machinery, can suddenly paralyse the working arm, and with it all those that depend upon its exertions, and can thus reduce thousands to the ranks of the disabled,—much more can sickness or disease. And whatever may be said by the speculative, we incline to think, upon high authority, that poverty and disease will ever accompany each other; and if ultimately they separate, it will be at a period very, very far distant from September, 1849. Until then, at any rate, we may hope and trust that the English nation will always recognise real destitution as a sufficient claim for support; and the superadded misery of sickness as a superadded claim for medical relief.

But what is to be the source of this medical relief? Whence is it to flow? Obviously, both kinds of assistance ought to come from the State; while it would scarcely be an exaggeration to assert, that at least half of it is at present thrown on the Medical Profession. Their services are in one way or another at the command of every man, woman, or child, within the realm; while a vast proportion of the assistance they render to those occupying a position below the scale of positive affluence is either not paid for at all, or so inefficiently as to render it partially, or to a great extent, gratuitous.

The medical advice given to the poor may easily be separated into two kinds. Directed towards the same objects, and flowing as it were in the same channel, this broad river consists in reality of two streams—like the Moselle and the Rhine at Coblenz. The one clear and sparkling, and of pure benevolence; the other an exceedingly dirty, turbid current of Poor-law Medical Relief. They run side by side, but do not mix. It is the muddy river we now intend to analyse. Upon the question of medical remuneration, as comparing it with that afforded to other Professions, we will not enter, fertile as the subject is in matters of deep thought and bitter sarcasm. We will not even contrast the workhouse Chaplain or the Clerk of the Board with the Union surgeon, although the comparative amount of work and pay would almost epitomise all we are about to state. We take a higher ground, and ask, not whether Poor-law surgeons are properly remunerated, but whether they are remunerated at all? Let us work out the answer.

The surgeon has to give two things—medical skill and drugs. Wherever the objects of relief are at all widely scattered, the laws of matter require a third element to be added to the contract—viz., the means of conveyance.

The last two elements being visible and tangible, and of a definite cost, we must, after making an estimate of their amount, subtract them from the total sum paid. The residue will be—the remuneration for professional skill.

But those of our readers who do know the nature of arithmetic, and do not know the nature of Poor-law Commissioners and Guardians, will be surprised to hear that this simple statement is incorrect. In the vast majority of cases the residue is—nothing at all.

We can imagine a grey-headed Union surgeon stepping forward, and again correcting our arithmetic. "Dear Mr. Editor," we hear him say, "I wish it were nothing at all. At school I was taught that there were such things as negative quanti-

ties. This fact my practice has never allowe me to forget, for the salary does not cover th expenses, and I am *minus* five or ten pound annually by the contract." We cannot bette illustrate the truth of these statements than b adducing a fact which speaks for itself. Ther are many Dispensaries, the Medical Officers which professedly give their time and skill gra tuitously, so that the sole expenses of the insti tution are those of the drugs and medical appl ances, where, as in some of them, no patient i received without a subscriber's letter of recom mendation. There the cost of each case ca easily be calculated, and, as a rule, it i considerably above that of the Poor-law con tract. We have known instances in which th average remuneration per case of the latter ha been scarcely more than half the average cos of the former.

How are we to explain this significant con trast? Say, rather, what is the result?

There are many instances—we believe they are the vast majority—in which the Medica man gives his strength for naught, and consc entiously performs his duties at a loss of time and trouble—it may be, also, of money. But there are other instances probably in which, as migh be expected, inefficient pay is met by inefficien services, and the shameful avarice of the rich is thus avenged upon the defenceless poor. God forbid such conduct should be defended; but it is impossible to avoid remembering that it is often negative and almost unintentional—an omission instead of a commission, an imperceptible habit instead of an overt act, or a necessary result of individual incapacity. But indefensible as it may be, it is no more than what might have been expected, perhaps, no more than was really foreseen by the inventors of that great "misery-test, of which medical relief thus forms a part. The constituents of this inefficiency are easy to trace. Neglect in visiting the sick pauper is the effect, though a much rarer one, we firmly believe, than wooden-headed jurymen and Dogberries are apt to believe. The quality of the relief itself is much more affected, both as regards the skill of the attendant, and the nature of the drugs. An inefficient Practitioner is sometimes the only man who will accept such an appointment. In other instances, a raw student, armed perhaps with the botanical medal for which he sold his medical education, underbids an educated Medical Practitioner, or an unqualified apprentice, or scarcely more qualified assistant, hidden behind the shield of his employer's credit and reputation, lets fly his fatal arrows with an effect that fully entitles him to the praises awarded by the Hebrew woman to Saul and David. The meanness of a pauper pharmacopœia may by some of our readers be deemed fabulous, yet it constitutes in reality one of the methods by which a sordid man contrives to make both ends of the contract meet.

Few, by comparison, as these instances may be, there is not the less stress to be laid upon them. They constitute, in fact, one horn of the dilemma, and enable any man of sense to see that the present system of Poor-law medical remuneration necessarily does one of two things,—either *cheats* the Medical man, or (we say it advisedly) *kills* the poor. One of the tw is inevitable. And we may also notice, the ver nature of medical relief requires not only that should be tolerably good, but the best that ca be commanded in the particular locality. Th ordinary difference established between th diet of necessity and of luxury finds n parallel in the case of medicines; unless, indeed, it can be proved that the poor are con stituted differently from the rich, and tha the difference renders them less liable t disease, and more amenable to remedies. Bu this physiological and therapeutical distinctio is scarcely established, and it is most importan to recollect that, so far as we know at present the poor really are of the same flesh and bloo as ourselves. Would that it were a truism t say so!

But it only remains for the Medical Profes ion and their organs in the public Press t lose no opportunity of pointing out the folly and, we may add, the criminality, of the presen system. Agitation is one of those things o which the statement, otherwise a very equivoca one, may fairly be made; viz., that success stamps it with propriety. And already there have been sufficient symptoms of yielding to he pressure from without, in the shape of the extras which have been allowed of late years. o make it very evident, that continued and reiterated exposure of the evils of the existing Poor-law Medical Relief, will finally lead t their removal.

THE COMMISSIONERS IN LUNACY. THE DEFECTIVE STATE OF THE LAW OF LUNACY.

The Commissioners in Lunacy have addressed a letter to the Lord Chancellor, expostulating upon certain opinions which were enunciated from the bench by the Lord Chief Baron during he recent trial of Nottidge *versus* Ripley. His Lordship is reported to have stated most emphatically, that no person ought to be confined n a Lunatic Asylum who is not dangerous either o himself or to others. "It is my opinion," said His Lordship, addressing one of the Commissioners, "that you ought to liberate every person who is not dangerous to himself or to others. f the notion has got abroad that any person may be confined in a lunatic asylum or madouse who has any absurd, or even mad opinion pon any religious subject, and is safe and armless on every other topic, I altogether and ntirely differ with such an opinion, and I dere to impress that opinion with as much force s I can do in the hearing of one of the Commissioners." The principle, so clearly and so umanely propounded by His Lordship, was eceived with acclamation by the Press; whilst, aturally enough, His Lordship's observations ave some umbrage to the Commissioners in unacy, and was received with dissatisfaction y the proprietors of Private Lunatic Asylums, hose interests would be seriously invaded if ich a recommendation were adopted. We find, herefore, Dr. Conolly—himself, the proprietor Lawn-house,—entering the field with "a reonstrance," in the first instance, with the ord Chief Baron upon the heresy of his doctrine; nd the Commissioners in Lunacy next addressg a letter, signed by Lord Ashley, to the Lord ligh Chancellor, respectfully submitting that "the opinions ascribed to the Chief Baron are likely seriously to mislead the Medical Profession and the public."

We have reason to believe, that the Medical Profession and the public are equally dissatisfied with the administration of the existing law of lunacy, which does not appear to provide any adequate protection for the liberty of the subject when accused of being insane; and which does not afford any guarantee that persons who, unhappily, are so afflicted, and whom it may be necessary to place in confinement, shall be treated with kindness and humanity. The present system is in all its bearings involved in darkness and mystery; the transactions which take place in the office of the Commissioners in Lunacy in New-street, Spring-gardens, are conducted as closely and as secretly as were the iniquitous proceedings in the Star Chamber of old in Westminster; there, questions affecting the liberty f the subject are summarily discussed and disposed of without a single reporter from the public Press being permitted to be present; yet in all cases where a person is found to be insane by a writ *de lunatico inquirendo*—that is, before a special jury, reporters are always admitted, who watch and report the proceedings. The secresy which veils the transactions that take place in the office of the Commissioners in Lunacy is, we believe, offensive to, and embarrasses even the proprietors and superintendents of these establishments themselves; for not unfrequently they find that all rules of courtesy and the principles of the common law of England are alike set at defiance. Then, again, the doors of Newgate itself are not more hermetically sealed against the admission of visitors and friends, than the gates of most private Lunatic Asylums; so that a person might, in such *quasi*-prisons, be immured for months, or even years, without the place of his detention being ascertained by those who may be most nterested in the discovery. And all this, be it observed, takes place under the jurisdiction of a Commission in Lunacy holding its inquisitorial meetings in the west end of the Metropolis, almost within a stone's throw of St. Stephen's. We do not, therefore, wonder that, ever and anon, cases are dragged into our Courts of law, the details of which excite a shudder in he public mind. Take, for example, this memorable trial of Nottidge *versus* Ripley. Here was a lady entertaining opinions more extravagant, it is true, than could have been suggested by any form of heathenism; nor do we doubt, for a moment, that they were sufficiently absurd and monstrous to evince a state of positive monomania; but how was she dealt with? Her demeanour is reported to have been, on all occasions, free from any indications of excitement; her manners were always affable and gentle, and however preposterous may have been her notions, she reasoned upon them with calmness and perfect self-consistency. "She was," observed one witness, "anything but a mad woman, and always quiet in her conduct." "She was always," stated another witness, "of a mild, calm, and lady-like turn of mind." Why, then, was she not permitted to enjoy her opinions in her own way, and live, if it so pleased her, in a world of her own fancies? The

reason is obvious. The lady possessed property; her immediate relations were afraid that she would, as other religious enthusiasts have done, assign it over to the favourite sect to which she had attached herself; and, in order to prevent this, they determined to have her certified as a lunatic, and shut up in an asylum. Accordingly, Medical men were consulted on the subject of her religious delusions, and the present lax mode of obtaining the certificates necessary for admission into a Lunatic Asylum were had recourse to. Hereupon her brother-in-law, with two other gentlemen, proceeded to the cottage, where she was living quietly and unobtrusively, effected an entrance at the back of the house, forced their way into the room where she was sitting, and, despite her tears, screams, and struggles, dragged her away without bonnet, cloak, shawl, or shoes, and forced her into a carriage, which drove off as fast as the horses could go to Hillingford-house. Now, with all deference to Dr. Stillwell's well known humanity, we think this banditti-like style of taking possession of a patient most reprehensible. She was not a furious or rampant lunatic; and there appears to be no manner of excuse for so outrageous a proceeding.

Here, then, was the lady, incarcerated for seventeen long months, during which period her case was brought six times under the special consideration of the Commissioners, and here was she denied the privilege of communicating with her other relations and friends, who in vain sought to discover the place of her retreat. The unfortunate lady at length effected her escape, and, although she was speedily recaptured and brought back to the Asylum, the place of her abode was now made known, and an inquiry set on foot, which terminated in her being discharged by the Commissioners themselves, who, be it observed, set her at liberty, while she still, as pertinaciously as ever, maintained the same religious delusions which had led to her being certified as a lunatic, and which the Commissioners previously held to be significant of insanity. Why, we may fairly ask, did they permit so cruel an episode in her history as her detention in a lunatic asylum for seventeen months, and then restore her to a liberty which she was, upon their own showing, as capable of enjoying on the first as on the last day of their visitation? "Was this lady dangerous, Mr. Mylne," asked the Lord Chief Baron, "to herself or to others?" "Not that I am aware of," answered the Commissioner. "If she were not so," retorted the Lord Chief Baron, "how was it that you kept her in this Asylum for seventeen months?" "My Lord," answered Mr. Mylne, "it was no part of my duty to keep her there." What! was she not confined in this Asylum under the very warrant of Mr. Mylne himself and his brother Commissioners? And was it not their duty to liberate her if they found her capable of enjoying her liberty in a rational manner? We do not wish to deal harshly with the Commissioners in Lunacy, who have difficult and responsible duties to perform; but we should like to know how many unfortunate persons may, at this moment, be immured in a similar manner, and denied all access to, or communication with, their friends? Such a system savours more of the rigours of a Bastille than of anything like an enlightened mode of managing Lunatic Asylums!

The principle laid down by the Lord Chief Baron, that no person should be confined in such establishments' who is not dangerous to himself or to others, is, we believe, sound;—but who is to determine whether a patient labouring under religious delusions be dangerous or not? Who can anticipate the hallucinations of the future—the voice or the vision—which may instigate the hallucinant to raise the homicidal or the suicidal knife? Not many years ago, in Paris, an apparently harmless visionary cut the throat of his wife and his three children under the delusion that he heard a voice from heaven commanding their blood to be offered up in atonement for their sins. "The difficulty of ascertaining whether one who is insane be dangerous or not"—the Commissioners, in their appeal to the Chancellor, observe, "is exceedingly great, and, in some cases, can only be determined after minute observation for a considerable time. It is the general opinion of experienced persons, that whenever an insane delusion exists, the patient can in no case be considered as otherwise than dangerous, although the tendency may never have been actually exhibited by overt acts or expressions; and, in our own experience, we have known patients whose disorder has appeared to have abated, and who have been treated as harmless for a considerable time; but who, nevertheless, upon some sudden and apparently unprovoked impulse, and without betraying any preliminary violence or irritation, have attempted, and in some instances have effected the destruction of themselves or others. In the cases of monomaniacs, and patients suffering under religious and other delusions (not apparently tending to any dangerous result), we have known repeated instances of their attempting and committing self-destruction, homicide, and acts of violence, owing to some imaginary sentence of condemnation, or under the influence of some imaginary voice or spirit."

All this we believe to be strictly true; but then, how came the Commissioners, with all their official experience before them, to discharge a patient who came under this very category, and who, the moment she obtained her liberty, assigned over all her funded property to the man whom she believed was God in the flesh. "The only fault," observes Dr. Conolly, "of which the Commissioners seem to have been guilty, was that of ordering her liberation from Dr. Stilwell's Asylum; but they thought her health declining, and could not foresee all the consequences." Save us from our friends! The declining health of the lady should have rather pleaded with the Commissioners for their further protection,—if, indeed, she required it at all,—instead of which, with her constitution impaired by anxiety and long confinement, with all her delusions thick around her, they resigned her to the tender care of Mr. Prince, the founder of the Agapemone, the abode of love.

The Lord Chief Baron, looking to the amount of property involved, and the circumstances of the gentlemen of the Agapemone having married three sisters so much older than themselves, and thereby possessed themselves of all their property, very properly observed, that marriage settlements ought to have been made, and that, in the present case, a medical examination and inquiry by commission should have been instituted. Upon which the Commissioners observe: "The opinion attributed to the Lord Chief Baron, that a Commission is necessary in all cases, in order to give the confinement the sanction of the law, appears to call for some remark. It is hardly necessary to observe, that proceedings by Commission are, generally speaking, advisable only where the insanity is likely to be of a permanent character, *and the property of the lunatic is of such a nature* as to require them, and of an amount adequate to meet the expense, always considerable, and, when the Commission is contested, frequently very large."

The Commissioners add, "That the finding of a jury is in no case essential, in order legally to justify the confinement of a person of unsound mind. In fact, out of 4,028 private patients (many of them possessed of considerable property) who were confined in Asylums on the 1st of January, 1848, only 215 had been found lunatic by inquisition."

This is truly lamentable! It would appear as if the property of the lunatic were the only criterion of his protection; for if his means do not afford the expense of his being found insane by a jury, the process for his confinement is simplified by the adoption of the forms prescribed by the present Act of Parliament (8 and 9 Vict. c. 100) which we have no hesitation in affirming are lax in the extreme, and liable to be abused. Two medical certificates are, it is true, required, each of which must be signed either by a Physician, a Surgeon, or an Apothecary, who may, it is true, not be in partnership, or in any way connected with each other, and the examination may, in each case, be separately conducted,—notwithstanding which, both these parties may have an indirect interest in the detention of the patient, or they may not have made a speciality of the study of Insanity, and be incompetent to pronounce a correct judgment. We lay it down as a principle which should be held inviolable, that no person whatever, who has any interest in the detention of an alleged lunatic, should be competent to sign any document that shall lead to his confinement. Who signed, in the present case, the order for Miss Nottidge's reception into Hillingford-house? One of those very relations who had an interest in her detention as a lunatic. Once admitted into a private Lunatic Asylum, what guarantee is there that the inmates shall be kindly and humanely treated? Not long ago a case was brought into one of our public Courts, of an unfortunate lunatic, who, being deprived of her income by some iniquitous relatives, was unable to pay the scale of charge required for certain comforts, and was permitted, consequently, to lie on the bare flag-stones, and denied the common necessaries of life. The visitation of the Commissioners, we are willing to believe, affords a certain protecting surveillance, but, with all their untiring energy and industry, their administration fails to carry out the objects of the Legislature; hence, whenever cases of this description are brought into Court,

the "secrets of the prison-house" reveal abuses which naturally excite a prejudice in the public mind against all establishments of this description. But we must here pause. A thorough revision of the present system of the Law of Lunacy is imperatively required;—the subject is one of great public importance, and we propose returning to it anon.

THE NEGLECTED FATHERS OF PHYSIC.

Five centuries ago, the opinions of Hippocrates and Galen reigned triumphant in the Medical world, and the Physician was considered accomplished, in proportion to the knowledge he possessed of the works of those celebrated men. The servile obedience rendered them for more than twelve centuries, by the practitioners of the healing art, was derogatory to the human mind, and injurious to the progress of science; and it was only by the efforts of some great master spirits, that medicine received a new impetus. Since the revival of learning in Western Europe, the authority of the "Fathers of Physic" has progressively declined, and in our day Hippocrates and Galen are ridiculed, instead of reverenced, and their voluminous writings remain undisturbed on the shelves of the few libraries in which they are found. It is singular that names once so celebrated should now be shorn of so much of their glory, and, did our space permit, we think it would be no unprofitable undertaking to trace out the cause or causes which contributed to their decline and fall. Science alone has not been instrumental in doing this. Truth is always just; for, while it will divest men of every honour to which they are not entitled, it leaves intact all that of right belongs to them. If, therefore, those once illustrious men had been arraigned at the bar of science, and had been there sentenced, they would now occupy an eminent position in the Medical world. The learned in all ages have be[illegible]sible of the merits of th[illegible] Fathers of Physic;" and it is to be regretted that the doctrines they taught, and the practice they adopted, have not been fully made known to the English Medical Practitioner in his own language. In speaking thus, we do not wish it to be understood that Hippocrates and Galen should again become models for our imitation, but that we may glean from their works all that is valuable, and reject all that is worthless.

In many of the sciences ancillary to medicine, their knowledge was far inferior to ours; in others they attained an eminence to which we have never yet arrived. Had we possessed a complete translation of the works of the Greek physicians, or had the language in which they wrote been more generally understood by us, we should not have awarded to some men of modern times, the merit of many discoveries in Physic and Surgery to which they are not entitled, neither would the great subject of hygiene have been so long neglected by us.

The works of Hippocrates and Galen contain a complete imbodiment of the practice of Physic in ancient times. It has been customary to call the former "the Father of Physic." To this appellation, however, he has no just title. There had been eminent individuals before his time who had studied and practised the healing art,—who were intimate with what is even now considered most essential in our science; for they knew and employed almost all the important and fundamental means of cure which have reached our times. Hippocrates, however, collected and condensed the great medical truths which had successively been developed in preceding ages, and to these he added the discoveries of his own exalted mind.

According to Galen, he held the first rank amongst philosophers as well as physicians. Even Plato paid the greatest deference to his opinions, and it is said that the writings of Aristotle are chiefly commentaries on his philosophy. His attention, however, to symptomatology is that which has principally gained him so much renown in the republic of medicine. He studied the countenance, the eyes, the position of the patient, his loquacity, or taciturnity, his respiration, his excretions, secretions, fæces, urine, perspiration, sputa, saliva, and tears. He is even said to have employed the sense of taste, in order to discover from the secretions the nature of the disease under which the patient laboured. His remedies were of the most active kind. He bled freely, employed aperients and diuretics, but his principal reliance was on dietetics, a subject which by us has been too much neglected, and in which none have ever surpassed him. He was a good surgeon, and appears to have performed many of the most important operations.

Galen, however, excelled Hippocrates in the extent of his information and in the eminence which he attained. For more than twelve centuries, he kept the Medical world in complete subjection, and the veneration in which he was held at one time was such, that men regarded him as a God, and paid religious worship to him. More than four hundred books are stated by Suidas to have been written by him on medicine and philosophy, and seven or eight immense folios of his works have reached our times. These are valuable from the large number of facts they contain, and will well repay the modern Medical Practitioner who shall peruse them. The faults of Galen, however, are many; yet they are chiefly attributable to the age in which he lived; and considering the numerous disadvantages under which he was placed, he is entitled to greater admiration for having left on record so many important facts. From the number of his writings, it is evident he was a man of indefatigable exertion; and in these times of inquiry, it is matter of astonishment that such an one is scarcely known except by name. A recent writer has justly remarked, that "Galen was no slavish and ignoble plagiarist. In thought, as in action, he appears to have been free; and those thoughts are evincive of superior genius, improved by all the arts and sciences of his own and of preceding ages. His works are a library of past events, an encyclopædia of facts from every branch of Medical literature, and forestalling many of the most extraordinary events of our own times; while, even in experiments and in operations, *considered as novelties* in the present day, he has preceded them."

It is to be regretted, that the works of these two great Medical Authors have never yet been entirely translated into English. Surely we have in our profession men of sufficient learning and courage to undertake the task. The numerous Latin Editions extant would considerably facilitate the labours of English translators, and we think their efforts would be appreciated by our Medical brethren. Why does not the Sydenham Society move in this matter? We understand this Society intends publishing the works of Hippocrates, and we hope that they will be followed by those of his illustrious Commentator. If the funds are adequate to the undertaking, we think there are scholars enough amongst us to accomplish the task.

THE PROPOSED CONFERENCE ON MEDICAL REFORM.

The Council of the National Institute, as we have before intimated, anxious to obtain the most extensive accordance of opinion that is possible, upon the subject of Medical Legislation, have resolved upon convening, in London, a Conference of Delegates, from all the Associations that have either opposed or supported the policy they have themselves advocated. The Colleges have had their Conference, and it is but fair that the unrepresented mass of the Profession should also have theirs, so that the interests of all classes should receive due consideration. The views of the Colleges are now clearly understood, and their policy is fixed to certain points and principles from which, without incurring disgrace, they cannot retire. Discussion has sobered their pretensions, moderated their ambition, and softened much of that ruggedness and asperity of demeanour which they have been wont to show towards their unprivileged brethren. Corporate interests which, through long years, had been allowed to grow up and sprout out in all directions, to the injury of other classes, and of the general welfare, have been clipped and trimmed, and something like a mutual adaptation to the claims of each, and to the necessities of all, has been arranged.

The Council of the College of Surgeons is, however, still refractory and unaccommodating, and refuses to grant the right in law of examining in surgery to the new College, without which that College would be a failure, so far as regards the lofty aspirations of its promoters. We presume, that the object of the proposed conference will be to take the sense of the Profession upon this point, the only point in dispute between the National Institute and the College of Surgeons, and which prevented legislation last session.

If the College of Surgeons will not concede the right in law of examining in surgery to the new College, shall it be compelled to open its doors to the Profession at large, and to assume to itself the important functions of a College of General Practitioners? A Board exercising these functions is a necessity of the day, and the Council of the College may depend upon it that the common sense of the public and the Profession will shortly ride down all opposition, and command a solution of the difficulty in one of the two modes now indicated. The Council must make its selection; it cannot continue to trifle with the great interests of the Profession,

or to mock any longer the hopes of its members. It is better to yield to a strong wind than to be broken down by a tempest.

The following is a copy of a Circular Letter issued by the National Institute, preparatory to the convening of a Conference :—

[Copy.]

NATIONAL INSTITUTE OF MEDICINE, SURGERY, AND MIDWIFERY.

Hanover-square-rooms, Hanover-square, September 5th, 1849.

I am requested, by the Council of the National Institute of Medicine, Surgery, and Midwifery, to forward to you the following copy of a resolution, passed unanimously at the General Meeting of the Institute, held at the Hanover-square-rooms, on the 8th day of August, 1849 :—

"*Resolved.*—That this meeting cannot too strongly urge upon their Medical brethren the necessity of united action ; and they recommend, that the Council of the Institute do forthwith convene a General Conference of Delegates from the various Associations that have been established for the purpose of effecting a reform of the laws governing the Medical Institutions of the Kingdom, for the special purpose of securing as extensive an union of sentiment and action as possible upon the main principles of Medical legislation."

I am requested also to state to you, that, during the last two Sessions of Parliament, the Institute has acted in concert with the Corporate Institutions of this country, for the purpose of obtaining an Act of Parliament reforming the laws by which at present the Profession is governed; in the earnest hope, and with the just expectation, that a conciliatory course of conduct would insure success. From causes, not originating with itself, which have been explained to the Profession, the efforts of the Institute, acting by its representatives in the Conference recently held at the Royal College of Physicians, have for the present been defeated by the defection of one of the parties from the principles to which the Conference had unanimously agreed.

Upwards of twenty years' agitation in the cause of Medical Reform, by numerous Associations successively, and of late years by the National Association and the National Institute, under different governments and the most variable circumstances, has tended only to confirm the truth, which developed itself at a very early period, that this great political, social, and professional object, is only to be achieved by opposing the combined efforts of the great body of the Profession against the narrow and exclusive policy of a small, but, from the defects of the laws, and circumstances of misrule and bad government, an influential and powerful minority.

The Council of the Institute, with ample opportunities of forming an opinion, are convinced that the continuous exertions of the Profession, during this long period, although hitherto failing to secure a consummation of the desired object, have told in favour of Medical Reform with a cumulative effect; and that, at the present moment, a combined effort, on the part of all classes of Medical Reformers, would lead to a speedy settlement of this great question.

I am accordingly instructed to intimate to you, that it is the intention of the Institute, forthwith, to renew its exertions, with increased vigour, for the purpose of obtaining a legislative enactment and a redress of grievances during the next Session of Parliament; and that it is the earnest desire of the Institute, and the object of the above resolution, to devise such a plan of operations as shall meet with that general co-operation among Medical Reformers which is so absolutely necessary.

In accordance with the resolution, and in furtherance of these views, the Council of the National Institute request me to inquire, whether it will be convenient to you to assist at the Conference intended to be convened in London, of all bodies who have evinced an interest in the settlement of Medical affairs.

It is contemplated that the proposed Conference should take into consideration a comprehensive view of all questions upon which a difference of opinion has subsisted between the various sections of the Medical Profession, and in particular,—

1. The practicability of obtaining a redress of the monster grievance inflicted by the Council of the Royal College of Surgeons; and of opening the College to its members, so as to avoid the necessity of a new incorporation; and the most expedient course to be adopted in reference to the position in which the Council of the College at present stands, in relation to the "Principles" of a Medical Reform Bill recently laid before the Profession.

2. The Apothecaries' Society.

3. The proposed new incorporation.

4. The propriety of convening a general meeting of the Profession at large, and the course to be adopted at such meeting.

The Council will feel obliged by an early reply to this application, and if   should signify intention to attend the Conference, due notice will be forwarded of the day and hour of meeting.

I have the honour to be ——

Your most obedient servant,

GEORGE ROSS, Secretary.

To ————

OUR CHOLERA TABLE.

We have again to call the attention of our readers to the extreme importance of collecting observations on Cholera, while this fatal disease is still rife among us. It will be really disgraceful to the science of the day if no light can be thrown on the nature of this complaint, if no rules can be deduced for treatment from the experience of the last six weeks. Observations are wanted, and if every practitioner would endeavour to record his cases, however briefly, some results might at any rate be adduced. The Table we lately published has met with the approbation of numerous practitioners, as affording an easy and useful mode of recording cases. We repeat that we shall be happy to furnish printed forms to all who will apply for them, and, if they are returned to us filled up after the close of the Epidemic, we will take care to analyze them carefully, and, at the same time, to see that justice is done to every observer who has thrown his mite of knowledge into the common treasury. But every one who is disposed to aid in this task must be up and doing, or else the period for exertion will have passed away.

REPORTS OF SOCIETIES.

DEVON AND EXETER PATHOLOGICAL SOCIETY, AT THE MEDICAL LIBRARY OF THE EXETER DISPENSARY.—SEPT. 7, 1849.

Mr. James in the Chair.

The Secretary (Dr. Tuthill Massy) stated that he had sent a circular to each member, calling them together to discuss the nature and treatment of cholera ; and as an introduction to that subject he would read for them what had been done for patients applying at the Dispensary with diarrhœa.

		Diarrhœa.
Tuesday, June the 19th, persons without a recommendation were admitted, and up to Friday, the 22nd, we had		15 cases.
2nd week, ending Friday, the 29th inst.		32 „
3rd „	July the 6th	56 „
4th „	13th	68 „
5th „	20th	105 „
6th „	27th	175 „
7th „	August the 3rd	165 „
8th „	10th	421 „
9th „	17th	529 „
10th „	24th	467 „
11th „	31st	668 „
Total....................		2,801 cases.

The fluctuation in those weeks has been very little, but the increase has been rather steady. The 7th week diminished by 10, and the 10th week by 62.

The following mixture was given, with very few exceptions :—℞ Mist. Camphoræ, ℥viij.; Conf. Aromat, ʒij.; Tinct. Opii. ♏ xl.; Sp. Ammon. C. ʒij.; Tinct. Zinz., ʒiv. dos. ℥i. ter die.

There were very few second applications, so we must conclude that this mixture did great benefit.

The ages of these applicants varied from infancy to old age, the majority being intermediate. Their occupations were those of mechanics, servants, and labourers ; the officers of the corporation of the Poor attended the paupers, so they are not included in this report. Up to the 5th week we had no second application for the mixture ; all appeared to do well, and no bad symptoms arose from checking a diarrhœa of one or two days' standing. The general condition of nearly all were unhealthy, and their habits slovenly and dirty. The description of locality and house from whence they came, were the crowded, dirty courts and alleys, where ten or more are huddled together in each small room, without air or light. Simple diarrhœa prevailed most, few had decided cramps or rice-water purgings. One out of the 467 cases of the tenth week terminated in cholera and died. Two out of 668 of the eleventh week terminated in cholera and died. Twelfth week, up to seven o'clock this evening, 809 cases ; three terminated in cholera and died. Applicants with vomiting alone got the following :—

℞ Ol. ricini, ʒiv. ; tinct. opii., ♏ xxx. aq. menth. pip., ʒiv. ; ft. haust. S. S.

Applicants with cramps alone got the following :—

℞ Æther. Sulph., ʒi. ; sp. ammon. c., ʒi ; tinct. cinnamomi, c., ʒi, ; aquæ, ℥iss. M. ft. haust, stat. sum.

This treatment was pursued with great success ; only a few evils arose from the mixture. One I will mention in a man whom I visited taking this medicine without benefit. He had incessant vomiting and abdominal pains, the cause being an incarcerated inguinal hernia.

If it will not be tresspassing too much on this Society, I shall read a few extracts which I made yesterday, on the many remedies that have been successfully used in the treatment of cholera.

To begin, I may remark, that if we acted under the belief that the premonitory bowel complaint is an effort of nature to expel the poison, as stated by Dr. Stevens, we should not have given an astringent mixture so extensively ; but theory is of very little consequence by the side of practice.

In a leading article of the *Medical Times* of Saturday it is stated, that not more than 6 per cent., out of 1000 cases of cholera, have proved fatal under the saline treatment of Dr. Stevens. Dr. Graves, of Dublin, says, that there is nothing to be compared to acetate of lead ; he orders a scruple of the acetate with two grains of opium into xx. pills, and gives one every half hour until the violence is moderated ; then he prolongs the intervals ; at the same time he directs an enema, with two ounces of mucilage of starch, six to ten grains of lead, and twenty drops of laudanum, to be repeated *pro re natâ* ; this, with sinapisms to the abdomen is his usual treatment. Others say there is nothing like creasote ; one-drop dose repeated every hour, or even at shorter intervals. Some adhere to the old plan of calomel and opium, from 10 to 20 grains, washed down with from 30 to 60 drops of laudanum in a glass of brandy ; those men say, bleed in the early stage. Camphor has got powerful advocates in Germany. Carbonate of ammonia in America. Chloroform has been praised in various places ; so has carbon and carbonic acid. The 1-16th part of a grain of strichnine, washed down with copious draughts of cold water, every two hours, has cured some. Dr. Weatherhead has suggested transfusion, joined with chloroform. Dr. Blackall recommends lime water and milk. Mr. James has proposed yeast. Mr. Tucker cured some cases with Devonshire cider. Dr. Richmond writes as follows of half-pint draughts of port-wine :—No sooner is it swallowed, than the spasms, vomiting, and diarrhœa, instantly cease. You are all familiar with Dr. Ayre's treatment, which proved so successful at Hull. Most, if not all, use frictions. These are at present the most useful remedies.

Mr. James : I think that too much has been imputed to diarrhœa ending in cholera ; for example, we will take the 809 cases of this week—three terminated in cholera—a very small number, indeed.

Mr. Woodman : Would those cases have ended in cholera if they had not been prescribed for at the Dispensary.

Dr. Barham : Yes, they might have.

Mr. James: That question has not been settled; anything that depresses the nervous power may give a predisposition.

Dr. Massy: Can you make a distinction between choleraic diarrhœa and ordinary diarrhœa.

Mr. James: The London Board of Health has done that; for they have put down choleraic diarrhœa in their printed forms.

Mr. Woodman: I think it is out of the question to put down rice-water evacuations as premonitory symptoms.

Mr. Woodman then read a case. The patient was an old man of 70, whom he saw in the collapse stage of cholera; pulse was hardly perceptible; skin and tongue cold; countenance shrunk; voice weak; with cramps, and whey-like evacuations. He gave ℈i. of calomel with forty drops of laudanum, with directions to take nothing but water. Mustard poultices to the stomach, and bottles of hot water to the feet.

Next day rather better; skin warm; tongue cold; no motion. To take five grains of calomel and ten drops of laudanum.

2 p.m.—Has been sick twice since morning. Repeat the calomel and laudanum.

6 p.m.—Re action established; has not yet passed urine. To take three grains of calomel and ten drops of laudanum.

11 p.m.—Going on favourably; complains of cramps in the legs. To take three grains of calomel and ten drops of laudanum.

Sept. 1.—8 a.m. Has had a comfortable night; passed six ounces of urine, the first for thirty hours; has had one whey-like evacuation. Calomel and laudanum as before.

Sept. 2.—Has had a greenish-black motion.

10 a.m. Pulse 90; urine regular.

6 p.m. Has had three dark evacuations.

Ordered, one third gr. morph., h.s.

Sept. 3.—Has had a good night. Continue morph.

Sept. 4.—All symptoms of cholera gone.

This is the fourth case he has successfully treated after this plan.

Dr. Pennell: The first case which occurred in Exeter (Mrs. Sylvester), the hot-air bath was used, and although the surface of the body was heated, yet the hands and feet were cold, and could not be got warm.

Mr. James: Would the hot-air bath raise the temperature of the hands of a dead body?

Dr. Pennell: I think it would.

Mr. James: John Hunter believed we had the power of producing cold as well as heat.

Mr. Amory: The saline treatment, so far as lime-water and milk. I have given it with benefit; but when the evacuations are tinged with bile, I give a little blue pill.

Dr. Barham: As regards the treatment of cholera by bleeding, as far as I saw it, it did not answer.

Mr. James: You will cut short an attack by bleeding. I have bled in the most complete collapse for a violent pain in the stomach.

Mr. Land: Where the attack was excessive he bled to 8 oz.

Mr. Webb: The congestion of the heart is relieved by small bleeding, 3 oz.

Mr. Land: Has bled to 30 or 40 oz. in two or three hours.

Dr. Massy: I have got a return from Mr. Hele of 73 cases, which he bled in 1832, by the order of Dr. Hennis and Mr. Stabback. Many were in a state of collapse. 57 died.

Mr. James: We must take those cases with some caution, as we do not know to what extent blood was taken. Opium is useful; it has the effect of throwing the blood to the surface, as we observe it in the treatment of ulcers.

As the meeting was about to separate, the Secretary wished to know, if he was to understand that the opinion of this meeting, respecting the treatment of cholera, is small bleedings with large doses of calomel in the early stage, and cold water *ad libitum*?

Mr. James believed it the right plan of this meeting to send forth no opinion.

Mr. Hunt would like to know, if the thrilling sensation given to the fingers from touching a cholera patient and its connexion with electricity, was understood?

Mr. Woodman: As it is now late (10 o'clock, p. m.,) I beg to propose a vote of thanks to Mr. James; this was at once seconded and carried unanimously.

	Cases.
11 weeks . .	2,801
12 ditto . .	809
Total .	3,610

6 died. All the others recovered.

REVIEWS.

The Philosophy of Animated Nature; or the Laws and Action of the Nervous System. By G. Calvert Holland, M.D., Physician Extraordinary to the Sheffield General Infirmary. Churchill. London: 1848.

It was our intention, at an earlier period, to have presented to our readers an analysis of the contents of the work before us. Various circumstances, and the difficulty of doing justice to the task within any reasonable space, have hitherto prevented the execution of our purpose.

The generality of the productions which fall weekly under our notice, are comparatively easy to review. Small space will often be found to contain the cream of an Author's views, the rest of his work being more or less a simple illustration of hem. Or the work may be largely the reproduction of generally acknowledged principles or docrines, leaving little room for any lengthened remarks. The work of Dr. Calvert Holland, now under our consideration, belongs to neither of these classes. It is throughout an original investigation, and one of an exceedingly high order, whether the novelty and comprehensiveness of its views be taken into account, the ingenuity with which they are supported, their importance if justly founded, or the correct and elegant literary taste which for the most part pervades its pages.

Dr. Calvert Holland is no stranger to the scientific world. He has been known for nearly a quarter of a century as an indefatigable and enterprising physiologist, and all his works unquestionably show untiring labour and a remarkable independence of thought. The latter quality, whether we consent to his views, or differ with him in opinion, gives to his productions a peculiar charm and value,—for whether we agree with him, or become convinced that he is wrong, he always presents some new phase, and points out new bearings of which we had not dreamed. We speak advisedly, and regret that a departure from established doctrines and opinions has been prejudicial to the attainment of that popularity which works of far less merit and importance have secured to their authors. We do not hesitate to assert, that had Dr. Calvert Holland confined himself to popular literature, and written for the many rather than for the few, he would have taken a high position among the much-read writers of the day. But men, and above all physiologists, do not like to be found fault with, or to have their imperfections exposed, and their doctrines disputed; and he who undertakes the task—and that whether he succeed or fail—may rest assured, that the scientific path he chalks out for himself will be exceedingly rugged, and beset with no ordinary difficulties.

The Medical Profession, however, ought to be grateful to any one who will break up the soil in any new direction—who will show new capabilities and resources of which we had not calculated. Our limited knowledge of the functions of life, of the nature of disease, and of the action of remedies, should, while it teaches us unceasingly to inquire, inculcate a spirit of liberality towards the labours of others. Not that the liberality should seduce us to look mildly on errors, or in any degree to spare them. To castigate them with unrestrained severity, is a duty which we have never shrunk from fearlessly exercising in the columns of the *Medical Times*, and it is one too sacred to be diverted from its legitimate objects.

The peculiarity in the Treatise of Dr. Holland is an attempt to establish the existence of a nervous fluid, and to trace its influence throughout the functions of animal and organic life. This is the first systematic attempt of the kind that has been made. Not that the belief in such a pervading agent is new; nor the doctrine without supporters among the most distinguished physiologists of past and present times. The facts and reasonings which Dr. Calvert Holland brings forward in illustration of his views are full of interest, and apparently fraught with much practical application. They certainly enable him to explain a multitude of phenomena which have hitherto been regarded as inexplicable. If it be altogether on hypothetical grounds, an hypothesis possessing these properties has, in all scientific investigations, a claim to attention. Its value consists in giving a new direction to the mind, and in collecting around the object contemplated a variety of thoughts and suggestions, which gradually originate new ideas and elicit new points of observation, until, at length, a position is attained for the survey of an extended field of phenomena. The application of the hypothesis to the explanation of them is the test of its accuracy. It is the trial of its strength. If found unequal to the demands made upon it, it at once breaks down. But, though it may have been a baseless creation, it is not without its value. The rearing of it, as well as the destruction of it, is accompanied with the exercise of thought, and to this it has been a renovating and an invigorating process.

The readiest mode, and the only one which our space allows, of conveying to our readers an idea of the contents of Dr. Calvert Holland's elaborate Treatise, is to give the titles of the chapters, which are as follows:—

The consideration of these subjects occupies above 500 pages, and the treatment of them necessarily connects the whole together. An analysis of the contents, so as to present what is salient and the most important, is quite beyond our power. We can, however, conscientiously recommend the work, not only to the medical reader as one of considerable interest and value, but to the philosophical inquirer, whatever may be the nature of his pursuits. The originality and the perspicuity of its views, and the literary taste displayed in it, reflect great credit on the talents, research, and acquirements of Dr. Calvert Holland.

CHOLERA CORRESPONDENCE.

LETTER FROM SIR ALEXANDER DOWNIE.

Sir,—I believe it was Abernethy who was wont to say, that when he commenced practice he had thirty-nine remedies for every disease, but that ere long he found thirty-nine diseases for which there was no remedy. This anecdote has been forcibly called to my recollection in reading the medical and *lay* journals since the alarming increase of the prevailing epidemic.

Scarcely a day passes that does not bring to light some new and infallible remedy, and yet these remedies are as different in their effects, pathological,

chemical, and therapeutic, as negative and positive. One practitioner cures with brandy and opium, another with cold water, a third with colchicum, a fourth with calomel, and a fifth with antimony. In short, there is scarcely a remedy in the Pharmacopœia, and there is not a system in medicine, heterodox or orthodox, that has not been vaunted in the treatment of this frightful disease. *Doctors differ*, and, as a natural consequence, the people die. The *Times* of the 12th has an able article on this subject, and has well exposed the cavilling of officials and the difference of opinion existing amongst the Profession, both being as lamentable in themselves as they are destructive to human life.

Now, Sir, although I am neither going to advance a new remedy, nor promulgate an original theory—for the wisest of men has said, and daily experience proves that *there is nothing new under the sun*—I may still be permitted to select from those already before the public, and to state the reasons for my preference.

After long consideration of the subject, and pretty extensive reading of *brochures* and journals, English, French, and German, I am decidedly of opinion, that the system of Dr. Stevens, as ably stated in your Number of the 1st, is by far the most simple, the most judicious, the most scientific; and if properly carried out, will be found the most successful that has yet been brought under the notice of the public. I will now state the reasons which have induced me to arrive at this conclusion. Last year, while residing in Germany, and during the prevalence of cholera in Prussia, I was curious to trace the progress of the disease during its former visitation in Europe; and taking up a map, I was struck with the fact, that it avoided certain localities; for instance, it prevailed at Cassel, the capital of the Electorate of Hesse, and proceeding southwards, it was arrested in its route close to Nawheim, in the same principality. This village having been for centuries famous for its saline springs, from which great quantities of muriate of soda or common salt are annually consumed in the Electorate, and exported into other States, the idea immediately struck me, whether the saline exhalation or the carbonic acid gas evolved from these springs might have had anything to do with the sudden arrest of the hitherto formidable progress of the epidemic. As Pope says,

"Mighty contests rise from trivial things."

My love of inquiry, or, to say the least, my curiosity was excited; I pursued the inquiry, and found that cholera neither then nor now has ever existed in localities containing springs yielding *carbonic acid gas*. In Germany I would instance particularly Carsbad, Töplitz, Franzenbad, Ishel, Marienbad, Kissingen, Homburg, Schwalbach, Kreutznach, and many others. In Russia I have found from inquiry, that the same phenomena has been exhibited; and even in this country, I will venture to say, that places possessing springs yielding water which contains these properties, in a far minor degree, have been entirely free, or, comparatively speaking, nearly so, from the pestilential disease now so prevalent. We have heard of no cholera at Cheltenham, at Leamington, at Tonbridge-wells, and few, if any, cases at Bath. Now, Sir, whether these facts, for facts I affirm them to be, are caused by saline exhalation, or the evolution of carbonic acid gas, I shall leave as an open question to you and your readers; at the same time, they confirm the treatment of the learned philanthropist, whose name has called forth these remarks. Should I have the misfortune to be attacked with cholera, I should certainly request Dr. Stevens' treatment to be employed, and I only hope that some skilful and enterprising chemist in this vast metropolis may be induced to prepare the various prescriptions recommended, so that they may be rendered available, either by some member of the family, or the nearest medical practitioner. The general introduction of the system into public institutions may form a matter for future consideration, either on their part or that of those interested.

As a preventive of the epidemic I would urgently recommend the plan which I pursue, and which, notwithstanding various premonitory symptoms from which I have suffered, has hitherto, happily, proved successful, viz., the plentiful use of aerated waters combined with plain diet. I mean the Fachingen and Seltzers, either as imported, or manufactured by Struve, at Brighton, or Hooper, in Pall-mall,—both equally good. Soda, or one of these waters, with milk, or uncombined, I believe to be the best preventive of cholera.

Excuse this long, though first, communication from one who is a sincere admirer of the increasing talent and research displayed by your Journal.

Your obedient Servant,

ALEXANDER M. DOWNIE, M.D.

55, Grosvenor-Street.

LETTER FROM DR. H. M. HUGHES.

SIR,—I have a very strong objection to appearing as a writer upon questions which are powerfully agitating the public mind; and I have, consequently, felt more than ordinarily disinclined to address you upon the subject of cholera at the present time. But when hundreds have died, and are dying around me, the weight of responsibility appears to me so awful, and the sense of duty is so overpowering, as to compel me to lay aside all private considerations, and to send you the following statement of facts, and the simple expression of opinion which succeeds it, for insertion in your journal at the earliest possible opportunity.

I am far from doubting the authenticity of the facts mentioned by others, however much opposed the result of their experience may be to my own; nor have I any reason to question that they will accord to me an equally honest desire to state the simple truth.

The result, then, of my observation of the effects of the now general method of treating cholera (almost solely by calomel) has been so mournful, so woefully depressing to my mind and spirits, that I feel assured I should fail in my duty to our common humanity if I did not make it known to the Professional public.

It may be premised, that all the cases of cholera which I have seen have been in consultation with other practitioners. I have seen no patients in the hospital suffering from cholera. In a considerable majority of the cases that I have visited, the disease had already far advanced when I saw the patients. But I have been called to cases in which calomel, in frequently repeated small doses, had been commenced very soon, indeed, after the onset of the complaint, and to one in which it was administered only an hour and a half after the first appearance of the disease, and assiduously continued up to a quarter of an hour of the patient's death—an event which, I regret to say, occurred only fourteen hours after he had been *perfectly well*. I have seen a great many cases, in which the frequently repeated small doses of calomel, and some few in which large doses, less frequently administered, had been commenced, and actively persisted in, before I had been called in consultation. With such administration of the mineral, when the patient was already in or approaching to a state of collapse, I have not usually interfered, for I have considered that it was not likely then to be injurious, and I have contented myself with recommending a liberal supply of cold water, or of ice; cold towels to be wrapped around the legs, for the relief of the cramps; sponging the body with tepid or warm water, and then enveloping it in warm blankets, and the use of any mild nourishment that the patient could take, together with a sparing supply of stimulants, preferring others to alcoholic stimulants. I believe that all, or very nearly all of the persons so treated have died. So common, indeed, has been this result, that latterly, when, upon entering the sick room, I have seen some dozens of powders upon the dressing-table, and have found the patient's tongue coated with white powder, like so much chalk or carbonate of lead, I have at length assumed, that his fate was almost certainly sealed. I regret to express my belief that I have *very rarely, indeed*, been mistaken. Such, Sir, has been the result of my own observation, of trusting to calomel in the treatment of cholera. Now, Sir, I beg to mention the experience of others in this vicinity, who had been so kind as to favour me with a report of it under their own immediate inspection. A Medical friend, and near neighbour, was induced to try the plan of small frequently repeated doses of calomel by the recommendation of one of the amiable superintendents of the "Board of Health." They were given, as he believes, constantly and regularly, and, as he truly observes, "There is no art and mystery in their administration, nothing can be easier." They were given in twelve consecutive cases. *All died*, and died, he says, more rapidly than ordinarily, though the patients were of different ages, and in various stages of the complaint, when the treatment was commenced. He says emphatically, "I will never trust to calomel again." Another surgeon significantly observed to me, "Either Dr. A. is mistaken, or the cholera of Hull is a very different complaint from the cholera of Southwark." A gentleman who, in the present epidemic, has, perhaps, seen as much or more of cholera, in this sadly-infected district than any other person, reports: "I have tried calomel in large and repeated doses, in thirty cases of cholera brought into the workhouse in a state of collapse; *not one of them recovered, and as to the small frequently repeated doses, I had tried them before, and found them equally inefficacious.* A practitioner of large experience, both in the present epidemic, and in that of 1832, told me, that he believed that calomel *had no effect in the cure of cholera*; though it might have some influence in mitigating the secondary fever, if the patients ever arrived at that condition. Another gentleman exclaimed to me, "As to calomel, Doctor, you may just as well throw it into the street; I believe that it lies in the stomach like so much white paint!" I find, moreover, that those to whom I apply, and who are still disposed to trust to calomel, have rarely had more than one case, or at most two or three cases, in which calomel, when administered alone, had been successfully employed, though dozens or scores may have died under its use. One gentleman said to me, "I really have seen two cases in which I believe it was the means of curing the disease; the one being a lady very susceptible of the action of mercury; the other a child." "And," I inquired, "in how many instances have you tried it and found it to fail?" To this he replied, perhaps somewhat loosely, "Oh! in a hundred! a hundred to two are certainly great odds!"

Now, Sir, as I have previously stated, I have no reason whatever to doubt the correctness of the assertions made, or the perfect authenticity of the facts reported by others, and for the facts and statements herein recorded I am, myself, responsible. There must, therefore, be a mistake somewhere; either the disease is much more virulent, and therefore less controllable here than in Hull and in other places, in which the small doses of calomel are found to be so wonderfully efficacious, or there must be some other source of fallacy to be discovered. Let, then, those who find calomel to be really efficacious continue its use; but, let me entreat those, who, in this and other vicissitudes, find it almost useless, to attempt some other means of checking the disease, for assuredly nothing can, so far as I have seen, be worse than this. If it does no positive harm, it necessarily entails the undoubted negative evil of preventing other more efficient means being adopted, and of thus losing valuable, most valuable time.

Finally, Sir, I would express my firm conviction of the communicability of cholera from person to person, independently of locality; whether that communicability be termed "contagion," or "contingent infection;" and of the high, the primary importance of stopping the huge drain from the alimentary canal, which drain, whether excreted from the anus, or merely secreted into the intestines, I believe to be the true cause as well of the collapse, as of the diminution or cessation of the secretion of bile and urine. For the purpose of stopping this drain, I have, myself, found nothing so effectual as a large dose of solid opium by the mouth, followed by astringents, ammonia, and opium in a fluid form, together with an enema composed of a small quantity of warm starch, and a full dose of laudanum. If these means are employed early in cholera, (and by cholera, I mean neither diarrhœa, however profuse on the one hand, nor the collapse of cholera on the other,) I believe that they will be frequently found effectual in checking the disease. They are certainly the most effectual means that I have employed, or seen employed. When collapse occurs, they must, of course, be laid aside. Then, indeed, calomel may be given; for then it can do no harm, though I verily believe it can effect no good. Then, so far as I have observed, the free administration of cold drinks, together with a moderate amount of stimulants, in the form of ether, ammonia, chloric ether, or turpentine; sponging the surface of the body, and wrapping it in warm blankets, are almost the only means, or, at any rate, the best means to be adopted, for the possible restoration of the patient. In three cases only, in my own practice, has the "packing in the wet sheet" been adopted; in two unsuccessfully; in the third, which was certainly *not* in a state of collapse, with the happiest results. Sir, I have now done; I have performed what I have conceived to be my duty; I have, at any rate, relieved my own mind. I trust that I may never have occasion again to address you upon the subject of cholera. As I have merely sent to you a statement of facts as they have occurred to myself; have given the reports of others as they have been related to me; and have expressed opinions without, I trust, anything offensive to the most delicately constituted individual, I hope I may be excused the painful task of replying to any objectors to what I have said, who may possibly feel themselves called

upon practically to deny, or theoretically to question the deductions from the communication of

HENRY M. HUGHES, M.D.
Assistant Physician to Guy's Hospital,
14, St. Thomas-street, Sept. 11th, 1849.

LETTER FROM DR. BEAMISH.

SIR,—I trust you will permit me a small space in your valuable periodical, to state the result of *eight cases of malignant Asiatic cholera*, (all but in collapse,) treated by me in the hospital of the County Cork Gaol, on the opiate plan suggested by Dr. Hawthorne, of Liverpool, in his very able and valuable pamphlet on the subject.

Out of the eight, (which occurred within the last fortnight) *seven* are now *perfectly recovered;* and in *only one case* was the narcotic effect of the medicine manifested. A man who had taken gr. xiij. of opium *at a dose*, who never after had a symptom of cholera, and has been for some days *perfectly recovered*. A woman took gr. xij. *at a dose* without *the slightest narcotic effect*; on the contrary, her expression was, "She would be quite well *if she had a little sleep*." This woman had (in addition to all the characteristic symptoms of the disease) slow and laboured breathing, with spasm of the diaphragm; and now enjoys perfect health. The doses in the other cases varied from gr. vj. to gr. x. for cholera cases; and for diarrhœas from gr. vij. to gr. iij. every third or fourth hour.

The one case which proved unfortunate, and to which I gave gr. x., was, I may say, *collapsed*, and though life was prolonged, (judging from the rapid progress of the disease under former modes of treatment,) and suffering mitigated, *without an appearance of narcotism*, still I should not, in future, be induced to employ it *in any case so closely bordering on collapse*.

In none of these seven cases was there a symptom of consecutive fever, which so generally followed other modes of treatment, and in which so many were carried off.

When cholera prevailed in this Institution, previous to this last outbreak, I had fifty-one cases, and lost twenty-four under the *acet. plumbi* and *morphia* treatment, which (having tried all others,) I found the most successful; and though this amount of mortality is by no means as large as it has hitherto been compared with other Institutions; still, judging from the result of those eight cases, I must, of course, regret very much, I had not met with Dr. Hawthorne's valuable views on the subject before now. However, I now lose no time in making the result of these cases public; and beg to add, that I have felt the greatest gratification and pleasure in witnessing their progress; whereas, before, I felt disheartened, and actually dreaded being called to a case, feeling that we really had not arrived at a remedy calculated to arrest its fearful symptoms, and in which (as in other diseases) we might naturally have confidence.

Should I meet with any other cases suitable to this mode of treatment, I shall let you know the result; and, in conclusion, beg to say that its employment requires *experience, discrimination*, and *careful modification*.

I am, sir, your obedient servant.
WM. BEAMISH, M.D.,
Physician County Cork Jail.
Sept. 11, 1849, 7, Camden-place, Cork.

P. S. Having taken accurate notes of the different cases, I shall be happy to afford *more minute* information to any one desirous of obtaining it.

LETTER FROM MR. MANN.

SIR,—Will you allow me through the medium of your columns to draw the attention of my professional friends to a remedy which I have found very useful in the treatment of the prevailing epidemic,—I mean the *liq. chlorinii* of the Edinburgh Pharmacopœia. During the last week I have used it in more than 200 cases, varying from the mild form of diarrhœa to very severe forms of cholera. It has invariably stopped all pain, vomiting, and purging; and I have only lost two cases, both of which were far advanced in the stage of collapse when I was first called in. The dose I give is from ʒi. to ʒiss., with water, every hour until the symptoms are relieved.

As I am not aware that this remedy has been used before in this disease, I trust you will give insertion to this note.

I am, Sir, yours, &c.,
C. W. MANN, M.R.C.S.E., &c.,
Medical Officer to the Northern District of Clerkenwell.

LETTER FROM DR. LINDESAY RICHARDSON.

SIR,—Entering lately on an extensive charge of cholera patients, under Dr. William Robertson of this city, and impressed by the reported beneficial results of Dr. Ayre's treatment of the disease, I deemed it a duty, alike to those entrusting their lives to my care, as to the advocates of this plan, to put it at once in operation. It has been my endeavour to fulfil, to the letter, the plan proposed, and to carry such out I have used every possible exertion. Calomel was given in two grain doses every ten minutes, accompanied by half, one, or two drops of the tincture of opium. I sat for nights at the bedside noting every change, and, when I did not administer it myself, I have every reason to place confidence in those to whom I entrusted it. The results, as seen by the accompanying Table, are far from satisfactory.

We have these eighteen cases of pestilential Asiatic, or malignant, cholera; selected, I confess, not, however, on account of the hopeless or moribund condition of such, but with a view to exclude any of a dubious nature. All must be aware, that during the prevalence of an epidemic like the present, many solicit admission into hospitals labouring under presumptive cholera; some may be cases of cholerine, but such I hold to be as distinct from pestilential cholera as ephemeral fever is from typhus, and as little entitled to a place, when the treatment is under consideration.

The treatment in question, then, was adopted in the first eighteen unequivocal cases which presented themselves.

There are several points worthy of attention in connexion with this Table:—

No.	Age	Sex.	State on Admission. Temperature, Expression, and Voice Natural; Pulse Natural, or a little Increased in Frequency. Serous Dejections.	Temperature reduced, Voice and Expression altered; Pulse small and frequent. Collapsing.	Temperature much reduced, Lividity; Voice Cholerale; Pulse Indistinct at the wrist; very small. Partial Collapse.	Temperature very much reduced; no Pulse at wrist; General Lividity. Complete Collapse.	Passed into Stage of Reaction.	Made water.	Mouth affected.	Lived after Admission into Hospital.	Amount of Calomel Administered.	Cured.	Died.

* This Patient survived the Cholera, but died of Pneumonia.
† This Patient survived the Cholera, but died of Peritonitis, probably connected with recent delivery.

1. I have arranged the cases according to their state on admission. No. 16 will be seen to be one in which the disease was but commencing, and in which, from my experience of other plans of treatment in such cases, might, I have little doubt, have been cut short.

2. Three, in which the affection of the mouth announced the systemic action of the medicine, died.

3. Two who survived cholera died, one of pneumonia the other of peritonitis, (the former, undoubtedly,) developed while the system was under the influence of the medicine.

4. Four, who passed through the stage of re-action, died without having voided urine.

5. In eleven there was not the slightest attempt at re-action.

6. Taking, then, the eighteen, one only was in life at the expiration of this plan of treatment.

After such a result, Sir, it can hardly be wondered that I cease to hope from the two grain doses of calomel.

I am, Sir, your obedient Servant,
W. LINDESAY RICHARDSON, M.D.
Edinburgh Cholera Hospital, Sept. 15, 1849.

LETTER FROM MR. LEIGH.

SIR,—The questions of the College of Physicians regarding cholera, as stated in your Journal of the 15th inst., I agree with you, ought to be put to every practical man in the country. Though, therefore, only a General Practitioner, yet, as having had experience of the cholera in 1832, I would reply to them as follows:—

1st. Quest. In 1832, a bargeman was brought to St. Ives, Huntingdonshire, with cholera, having come from a place where it prevailed, of which disease he died in a few hours. Two women were sent from the workhouse to attend upon him and the family, who washed the deceased's clothes. In a short time they were seized with cholera in the workhouse and died, and the disease spread in the house and in the town, the last person who died being the master of the workhouse himself. There was no cholera in the town before the man was brought home.

2nd Quest. In the great majority of fatal cases, coming under my notice, the people were poor and took little or no heed against deficient ventilation, or damp, or foul air, and were especially regardless of cleanliness in their privies.

3rd Quest. Rather a state of fullness than otherwise, which, in other diseases, would require purging, and often bleeding.

4th Quest. Shooting pains about the body, like rheumatic pains, and diarrhœa.

5th Quest. Frequent colourless evacuations.

6th Quest. I cannot here answer in the affirmative. Innumerable cases occur of diarrhœa in cholera times which are checked, but it is not clear that they have ever been exposed to the vicinity of a true cholera case.

7th Quest. I have all along thought, that the affection of the intestinal mucous membrane in cholera is a secondary, and not a primary affection; and that the disturbance of the system, as in small-pox, begins; the vomiting and purging, therefore, being only efforts of nature to throw off something hurtful, as in poisoning.

8th Quest. One of the women referred to in No. 1 had neither purging nor vomiting after she was seen by me. The people said, she had been to the privy once. She died more quickly than usual. As far as my memory serves me, in four hours or less after I was sent for.

9th Quest. Some re-action and return of colour to the surface, and, indeed, a comparatively natural appearance, but great weakness; but still not enough to account for death in three or four days, which usually came on.

10th Quest. The functions of the kidneys in the consecutive fever appears to be restored; at least, urine is passed, but still the fever goes on fatally.

I ought not to conclude without stating, that I find strongly rubbing the body in a hot salt-water bath the best remedy, or, indeed, rubbing the body all over with common salt.

The collapsed stage has been recovered from under this treatment, and a turpentine glyster has come next in efficacy.

Yours obediently,
JOHN LEIGH.

ON THE REMEDIAL APPLICATION O EXTREME OR BENUMBING COLD.

[To the Editor of the Medical Times.]

SIR,—I rely on your sense of justice for the insertion, in the next Number of your Journal, of the following reply to the Article in the Number of th 15th inst., on my recent proposal of the use of severe cold in the treatment of cholera and other diseases.

I am not surprised at this reception of my effort to mitigate the terrible epidemic which is now raging; and of the announcement of the powerful and extensively applicable remedy which I have discovered in intense, or benumbing cold. Greater medical improvements than this have been, at first, no better received, when discordant with commonly received notions; and I am willing, notwithstanding the particularly gentlemanly and dignified style in which it has been conducted, to defend a valuable remedy, still in its infancy, from this attack which has been made upon it, and which might hurt it in the estimation of the readers of your Journal.

In every communication which I have made on congelation, I have admitted that the medical use of it is opposed to the common opinion on the subject; and I have endeavoured, on most occasions, to explain the fallacy of this opinion. I have shown that the error has arisen from not discriminating between a short and limited congelation, and one of great duration and extent; and that it would be as unreasonable to prohibit bleeding and narcotic draughts in disease, because persons have bled to death from wounds, and been poisoned by swallowing large quantities of opium or prussic acid, as to condemn severe cold because persons exposed to a long continuance of this have been frost-bitten, or have suffered from sphacelus. Every powerful agent, when employed as a remedy, requires limitation and control. I have said that any one can, with very little trouble prove the safety of congelation, by dipping a small bit of ice into salt, and applying it closely to the chin In less than half a minute the part will be frozen and if the frigorific be now removed, the only consequence, besides the anæsthetic and other effects on which the remedial efficacy depends, will be a slight blush, or congestion, of a few hours' duration.

The relation of numerous cases, of various diseases, in my lately-published Treatise on Headache, treated by congelation, at a public institution, and often in presence of other medical men, was surely sufficient proof of its medical efficacy; and the same observation applies, so far, at least, as regards its safety, to the published cases of cholera treated by frigorific draughts.

But the writer of the article says, that "the alleged facts contradict all our past experience and all our received views in relation to living action; and, moreover, objects to the proposal of congelations, "because it is new to the practice of medicine." I must ask, in reply, when we had experience of *short* and *limited* congelation before it was used remedially and anæsthetically? and whether it is a sufficient reason to distrust an experimental fact because it does not accord with preconceived theoretical notions? The objection to this therapeutic agent on account of its novelty is one that could only be received were the science of medicine at admitted perfection; nor is the observation of our critic, that refrigeration must be bad in "so exhausting" a disease as cholera, of a superior description—seeing that the very purpose of its employment is to prevent exhaustion by checking the profuse morbid discharges which occasion this.

Another remarkable observation in these strictures, is, that "the swallowing of ice, and also the enema of iced water, are well established and most beneficial remedies"—but that "a host of facts show that cold spring water as well as ices, in warm weather," have, under certain circumstances, proved pernicious. Where is the opposition here? Of course, nothing can be termed a remedy that is not used under appropriate circumstances, nor can any medicine be given at all times innocuously. Now, if ice has been deemed "a most beneficial remedy," why should not a greater degree of cold than that of melting ice, properly applied, possess greater power? Is there any reason for fixing the degree of cold (as the Reviewer says the therapeutic rule orders) at 32 deg. Fahr., because water happens to freeze at that temperature? "Our medical works," says the Reviewer, "abound in cases of sloughing from the incautious continued application of snow or pounded ice as a refrigerant to external parts." I am not aware that our Medical works abound in any such cases; and what have the few related instances of mischief from incautious continued application of cold to do with the propositions under consideration? The Reviewer terms my proposal, one "to reduce the temperature of the stomach to that of the zero of Fahr." This is not the case. I propose the exhibition of frigorific mixtures, to lower the temperature of the stomach more than ice will reduce it; but I conceive it would be impossible by the means which I recommend to reduce the temperature to nearly the degree mentioned. Whether it could be so reduced with advantage is another question. It would be impossible to lower the temperature of the surface of the body to zero unless the dissolved salt were constantly allowed to escape, in order to maintain the necessary temperature.

But, granting that there was danger in the remedy I have proposed, which the experience of its use in cholera and analogous cases entitles me to deny, is that an insuperable objection to it? Are not the remedies applicable in dangerous circumstances of disease, generally to a certain extent hazardous of themselves? Is it not often a matter of calculation, whether greater risk is incurred by the remedy employed in such dangerous circumstances, or by the disease let alone? In the same Number of the Journal, an account is given of some cases of cholera, treated by phosphorus, in doses twice as large as the quantity of this substance, which, the writer of the paper informs us, on the authority of Mr. Taylor, has destroyed life. Have not, in fact, the majority of the remedies which have been employed in the advanced stage of cholera, been of dangerous character? I consider the safety of severe cold, as a remedy for the hæmorrhagic stage of cholera, to be one of its principal advantages.

I am, Sir, your most obedient servant,

JAS. ARNOTT.

Brighton, September 17, 1849.

[As in duty bound, we give a place to Dr. James rnott's letter, and that although much pressed for space. From this cause, we must refrain this week from commenting upon it, but will take an early opportunity—probably, in our Students' Number—of re-turning to, and re-considering the subject.—ED. *Medical Times.*]

NEW CUSHION FOR THE TREATMENT OF FRACTURES.

[To the Editor of the Medical Times.]

SIR,—Will you allow me to call the attention of he Profession to a cushion for the treatment of fractures, which I have of late used with great success, and which is, so far as I am aware, perfectly *new* in surgery.

The old plan of making cushions with tow, bran, sawdust, &c., appeared to me exceedingly clumsy and awkward, as there was scarcely any chance of procuring *equal pressure* by these means, and the patients were continually complaining of the splints hurting here and there, which, in fact, was not caused by the splint, but by the hard and unequal cushions.

To obviate this, the idea of substituting an *inflated Indian rubber* cushion struck me, as, by it, *equal pressure* on the injured part would be readily and easily procured. I accordingly ordered two cushions of this material, and having, at the time, under my care a lady with a compound fracture of the leg, whose constitution was exceedingly delicate and nervous, I removed the old cushion, and put on the Indian rubber ones. On visiting her next day, her first exclamation was, "Oh, how nice these cushions are; I have had such a sweet sleep!" The leg had been broken a week previously. Lately I have tried them in a case of simple fracture with the same good results. The make of them is very simple. Two pieces of Indian rubber, of a proper length and breadth, joined together in the form of a bag, having, at the superior and upper corner, a *small stopcock* of brass inserted, whereby they can easily be inflated, at pleasure.

One excellent advantage which they possess is, that when the leg becomes swollen and painful, instead of loosening all the bandages or tapes, relief can *instantly* be given, by merely *unscrewing* the cock to let out some of the air in the cushion. This simple process caused no *jarring* in the leg, or any additional pain to the patient.

I hope that the Profession generally will give them a trial, as I am convinced, from experience, of their superiority to all other cushions.

I am, Sir, your obedient servant,

Stokenchurch, Sept. 17, 1849. H. HASTINGS.

POOR-LAW MEDICAL APPOINTMENTS.

[To the Editor of the Medical Times.]

SIR,—In the *Medical Times* of the 18th ultimo, appears a communication headed "Poor-law Medical Appointments," in which the writer, who signs himself "Agricola," proposes a remedy for the numerous grievances under which the Union Medical Officers suffer. Now, a slight perusal of this correspondence will at once prove the incompetency of "Agricola" for the task which he undertakes. In the first place, he begins by an erroneous statement, saying, "it is notorious that the great majority of those officers are young men." Such is not the fact, but, on the contrary, the great bulk of them are men of middle age, and practitioners of several years' standing; and the reason why they hold their Union appointments is for the purpose of preventing strangers making inroads on their private practices. This, I thought, was sufficiently notorious already. I am myself acquainted with the Medical officers of several Unions, and not one of them is a young man. Again, "Agricola" says, "the poor are most inefficiently and negligently attended by these low-priced medical men. Instead of proper medicines, &c., they too frequently substitute mutton, beef, brandy, and gin." What a sapient cure-all is "Agricola." So, when he finds a poor frame-work knitter, emaciated and wasted from want of food, instead of ordering him a draught of porter and some beef, he makes him swallow quinine, bark, iron, &c., &c., and has full faith that his "proper medicine" will clothe his patient's bones with muscle, and give energy to his nerves. Blessings on the dear man! No doubt his neighbours are truly happy in having such a doctor among them, and, no doubt, he would be a useful and pliant tool in the hands of a Board of Guardians. But how does "Agricola" propose to get rid of cheap doctors? As follows:—"Let every Board of Guardians engage, as Medical Officers, all properly qualified medical men, residing in every district, who may be willing to act as such at a given sum per sick person during the year. That the sum for every such sick person shall be at least 2s. 6d., however long or frequent the illness may be during the current year." Now, if that is not cheap doctoring, I know not what is. Two shillings and sixpence for every sick person for one whole year, and most likely all such sick some miles from the doctor's residence. Surely the man cannot be serious. The Union Medical Officers have been trying for the last two years to obtain an alteration, which would average five or six shillings at least per each sick case, and this sum would only be a very moderate compensation indeed for medicine and attendance. The various Benefit Societies, such as "Odd Fellows," "Druids," &c., pay from three to five shillings each person, sick or not sick. "Agricola" also says, "It has always been a matter of regret among the poor that they cannot choose their own doctor." Now, I unhesitatingly say, that there could not be a worse evil attendant on the Poor-law system than allowing the poor to choose their own doctor. Independently of the poor being totally incapable of judging of the qualifications of Medical men, it would be a source of endless discord among the poor, and of inexplicable difficulties to the Guardians; as well might the poor have the appointment of surgeons and physicians to the various hospitals and other charitable institutions throughout the country. The poor, it is well known to Guardians and Medical Officers, are far more difficult to be pleased than their superiors, —no class of persons more ungrateful and dissatisfied, no matter what is done for them. Now, set up a rivalry among Medical men in their attendance on the poor, and, twixt the faithful discharge of their duties, and their anxiety to please the Guardians, you may rest assured that nothing but disappointment and thorough disgust would be the result. Nothing can or will remedy the present evil but to make Medical officers independent of Guardians and poor, by making their appointments permanent, and the remuneration commensurate with their labours.

Sept. 7, 1849. RUSTICUS.

IRISH MEDICAL CHARITIES.

[To the Editor of the Medical Times.]

SIR,—In your able editorial article on the Irish Medical Charities, justice is scarcely done to the Central Board of Health.

I have no hesitation in saying, that the gentlemen composing that Board, by a firm yet courteous administration of their duties, have won the confidence of the majority of the Profession in Ireland. You will say this assertion is contradicted by the memorial condemning the Board, which was signed by twelve hundred Medical Practitioners. Believe me, many who unguardedly signed that document now regret having done so. They are beginning to see that the Board showed sound discretion in keeping the con-

fidence of the Executive, by a proper regard for economy, and retaining the position by which they could afford countenance and protection to their professional brethren. Had the clamour raised against them driven the Board of Health to throw up their office, would the Profession be better off in dealing with Boards of Guardians? Quite the contrary; for in every attempt made by the several Boards of Guardians to reduce the salaries of medical officers, the Commissioners of Health have refused to sanction any such reduction.

I am, Sir, your obedient servant,

J. M.

MEDICAL NEWS.

Apothecaries' Hall.—Names of gentlemen who passed their Examination in the science and practice of medicine, and received Certificates to practise, on Thursday, September 13th, 1849:—John Merriman Fewkes, Barrow-upon-Sour, Leicester; William Robinson, Gateshead, Durham; Robert Wailes, Leeds; Thomas Wade, Hull.

War Office, September 18.—45th Foot—Assist.-Staff Surg. Alexander Gibb, M.D., to be Surg., vice Menzies, appointed to the 6th Foot; Surg. Duncan Menzies, from the 45th Foot, to be Surg., vice Robertson, promoted on the Staff. Hospital Staff—Surg. Peter Robertson, M.D., from the 6th Foot, to be Staff Surg. of the First Class, vice Robert Sillery, M.D., who retires upon half-pay; Acting Assist.-Surg. Charles Walter Poulton to be Assist.-Surg. to the Forces, vice Gibb, promoted in the 45th Foot.

Obituary.—Died, Sept. 9th, of Asiatic cholera, after thirty-three hours' illness, Mr. Richard Simon Edsall, surgeon, of Bermondsey, aged thirty-six. Mr. Edsall practised in Bermondsey for many years, and by his modest, gentlemanly conduct, won the regard and esteem of his professional brethren, whilst his kindness and attention earned for him the affection of his patients. His manners were unassuming, yet he was a sound, able, and successful practitioner; and it will be long before his memory will cease to be cherished, or the loss his death has occasioned be so ably and usefully filled.—Lately, at sea, Harry Goldney, Esq., surgeon, R.N.—On the 10th inst., at the house of his brother, in Bedford street South, Liverpool, aged 33, Emil Lemonius, M.D., of Berlin.—On the 8th instant, at his residence, Wellington-house, Stoke's-croft, Bristol, aged 26, of cholera, Joseph Williams, jun., surgeon.—On the 9th instant, at Delapré-house, Bridport, Robert Graves, M.D.—Recently, at Offenbach-on-the-Main, Dr. Carl Ferdinand Becker.—On the 10th instant, after a protracted illness, aged 58, Professor William Warenne, lecturer on anatomy, physiology, the fine arts, &c., late of Glasgow.—On the 17th inst., at his residence, Chesbunt, Herts, Edward Harrold, Esq., M.R.C.S., in the 81st year of his age.

Boards of Guardians and Medical Officers.—At the last election of Medical Officers for the Cheltenham Union, a majority of the Guardians made an effort to supplant Mr. Hyett, who had for ten years served the parish. They succeeded in finding a candidate to compete with him, and they elected the new and untried man by a majority of two. This gentleman's appointment was not sanctioned by the Poor-law Board, in consequence of insufficient qualification. The Guardians were forced to advertise again, and again they brought forward an opponent to Mr. Hyett, and, as before, elected him. A new Medical Officer was appointed in his place, and Mr. Hyett retired from the duties of the office; but not until he had served the Union for some time after the expiration of his annual appointment. For the visits paid during this interval he sent in a bill of 33*l.* 1s. 6d., charging moderately for his various attendances. The Guardians refused to pay the charge, pronounced it exorbitant, seeking to pay after the ratio of annual salary. Finding the demand persisted in, the clerk of the Guardians was instructed to tender, once for all, the sum of 20*l.* In order to make this tender legal it was offered unconditionally, and it was as unconditionally received and acknowledged. The Board were shortly afterwards informed by Mr. Hyett's solicitor, that if they did not pay the balance, they would be sued for it in the County Court. It was resolved by this body to defend the action, and instructions were given to their clerk to act accordingly. In due course the cause came on for a hearing before James Francillon, Esq., the district judge. The cause was about to proceed, after a discussion as to the power of the Court to decide the matter, when an offer was made by the defendant's attorney, to adjourn the case for a month, to take the opinion of the Board as to whether they would abide by the decision of the Court. This was consented to on the other side, and the adjournment took place accordingly.

The Cholera.—During the past week, we are happy to find that the mortality, from cholera, has decreased, both in town and country, and has been gradually diminishing since the Registrar's Report. A portion of this document we subjoin, and would beg to direct the attention of our readers to the excellent remarks which are made in reference to "preventive medicine." We have, on former occasions, showed how greatly this department of our Profession is neglected by modern physicians; but we hope that, ere long, our licensing Corporations will insist upon this branch of study being cultivated, and that candidates for their diplomas will be examined in their knowledge of hygiene:—

The deaths registered in London in the week ending Saturday, September 15, were 2865; of which 1682 were by cholera; making the aggregate numbers since the commencement of the Epidemic in London, 12,837. The deaths from all causes in the last six consecutive weeks were 1909, 2230, 2456, 2796, 3183, 2865. The numbers last week sensibly decreased.

Thousands of the houses of London have now no pure water; in some places where the cholera is most fatal, the inhabitants are driven to use the polluted waters of tidal sewers for culinary and household purposes. This state of things will exist no longer; the first engineers of the country will be employed to lay the rivers under contribution, and in every house there will be a spring of fresh, filtered living water; for circulating water is the life-blood of a city.

The bodies of the dead, "sown in corruption," will be decently interred in distant grounds, and sacred groves, where their flesh may be resolved into its elements, without tainting the air and destroying their brothers.

The carnage of slaughtered animals will no longer be suffered to infect the air of cities.

The sinks and sewers of London black, bubbling lakes and rivers under ground—extending from the Thames to the house-drains and cesspools, send up damps into dwellings nightly, travel by us in the streets daily, and through a thousand mouths by the way and river-side pour their poisonous incense on the passengers for ever: these emanations, if not drawn through and decomposed by fire, will no longer open under our faces, but ascend with the smoke over the houses; and other matters be carried, solid or in streams of water, over distant fields.

No city, perhaps, ever possessed such an efficient body of medical men as are now practising in London. During this Epidemic they have performed services which in any other field must have won the highest honours; combating the disease night and day in the most pestilential quarters, and that on much more settled principles than the public might be led to suspect from certain discussions at the Medical Societies. And their office has been discharged with so much kindness as to deserve the gratitude of the poor; instead of drawing down on their heads the charges with which the physicians of other countries have often been assailed by the populace. Nearly all the sick have been seen by these practitioners, yet 12,837 persons have already died of cholera in London. How is this? The medical force will be found to have been employed at an immense disadvantage. It is called into action at the wrong end of the malady. Inquiries prove, that while medical advice is generally sought in the characteristic stage, it is seldom obtained in the premonitory stage, when the power of medicine is decisive; and to that earlier and still more important period preceding the premonitory stage, which is prevented as easily as cured, medical practice has had little or nothing to say. Cholera here also only shows in high relief what exists in ordinary circumstances. Medical men rarely, if ever, treat the beginnings of diseases, and are scarcely ever consulted professionally on the preservation of the health of cities or families. The art of preserving health is taught in no regular course of lectures at any of the great schools of medicine in the United Kingdom. Yet the classical sanitary works of Pringle, Lind, Blane, Jackson, Johnson, and Martin, have been framed from observation in the British navy and army. In the science of health there are more exact, demonstrable truths than in the science of disease; and the advantage of "prevention" over "cure" requires no proof. In the Cyropædia of Xenophon, Physicians who only treat the sick are compared to "menders of torn clothes," while the preservation of health is declared a noble art, worthy of Cyrus himself. Vegetius speaks in similar, Jackson in stronger terms, but perhaps unjustly: for if it is godlike to save many from suffering, and to carry them in healthy life up to the natural term of existence, it is a worthy occupation to rescue a few from the arms of death or incurable infirmity. But the preservation and restoration of health are parts of one science; and if, as has been done by London and Liverpool, health officers be appointed in all the districts of the Kingdom, the art of preserving health will be studied by a high order of men well paid by the public; and ultimately with an increase of their remuneration,—the diminution of sickness, the disappearance of epidemics, immense advantage to the public,—the whole Medical Profession may devote themselves to the preservation and development of the vigour of the human faculties, instead of being tied down to the treatment of the sick and dying. "And this," Lord Bacon says, after his great survey of learning, "we hope might redound to a general good, if physicians would but exert themselves, and raise their minds above the sordid considerations of cure; not deriving their honour from the necessities of mankind, but becoming ministers of the Divine power and goodness, both in prolonging and restoring the life of man, especially as this may be effected by safe, commodious, and not illiberal means, though hitherto unattempted. And certainly it would be an earnest of Divine favour if, whilst we are journeying to the land of promise, our garments, those frail bodies of ours, were not greatly to wear out in the wilderness of this world.

Saline Treatment of Cholera.—The *Worcester Herald* of Saturday, the 15th of September, says, "That the value of this mode of treatment does not rest altogether on its services in 1832, for it has been tried as a remedy against the epidemic, although unhappily to a limited extent only, during the present year, in various places, and with success quite as extraordinary as attended its application in 1832. In this city (Worcester) it has been applied, in private practice, by three Medical gentlemen within our own knowledge, with most entire success. And, although in the cholera hospital it was not *permitted* (a) to have a fair trial, yet out of eleven cases in which it was applied, in ten it was quite successful in removing the cholera. In Sligo, Ireland, where the disease was very prevalent, Dr. James Tucker, during the month of August, applied the saline treatment to the patients of a dispensary in that town, of which he is the Medical officer, and he states, 'The trial I have given of it satisfies me, that it is the only proper practice." Dr. Tucker also states, that on inquiry of some of the practitioners appointed to attend the cholera hospital in Sligo, they told him that the saline treatment had been the most successful. Mr. Henry Mudge, surgeon, Bodmin, who has issued a tract entitled, 'Asiatic Cholera, and its Treatment,' says, 'I believe the saline treatment meets with determined opposition, *because it is the best as yet known.* Metaphysicians may explain it; but 'tis an historical fact, that truth has to fight its way in the world inch by inch! This has been the case in the healing art. Sydenham was condemned for treating fevers and small-pox on the cooling plan; Harvey was persecuted for teaching the circulation of the blood; Jenner was anathematised on account of vaccination; and Hope, only twenty years since, was ridiculed for using and praising the stethoscope! 'Tis the old story over again.' We are afraid that there is too much truth in this, strange and pitiful, indeed, as it is; but, as it would seem some of the Profession have determined to scout even a fair trial for so important a matter as a cure for cholera, it becomes the province of the Government to inquire into the merits of the treatment."—(a) [If the Medical gentlemen in charge of the Worcester Cholera Hospital will *not* tell us why the saline treatment of cholera was not "permitted" to have a "fair' trial, per-

haps the Editor of the *Worcester Herald*, or some one of the Worcester Medical men, will do us and the public that favour.—ED. *Med. Times.*]

THE BOARD OF HEALTH PROSECUTIONS.—The *Gazette* of Friday week contains instructions from the Board of Health to their Secretary to prosecute several Metropolitan Boards of Guardians and Managers of burial-grounds for wilful violation and neglect of orders issued by the Board to prevent disease and nuisance.

THE CHOLERA IN DUBLIN.—Within the last two days there has been, not merely an abatement, but an almost total cessation of the disease in and about Dublin.

CHOLERA IN PARIS.—According to the returns of the Sanitary Commission in Paris, it appears that out of the 19,750 deaths which have occurred in that capital from cholera and diarrhœa, the mortality among the troops has been very great, being upwards of 5,000, notwithstanding all the sanitary precautions. This appears to have been greatly in consequence of the hard duty the garrison has to undergo, the want of proper sewerage and ventilation in the barracks, but more particularly the water. The garrison of Paris and environs is from 65,000 to 70,000 men, not including the National Guards.

THE JEWS AND THE CHOLERA.—It is stated in the *Times* that not a single fatal case of cholera has occurred amongst the Jews in Houndsditch, or the close and badly-ventilated vicinity of Petticoat-lane, a neighbourhood not over remarkable for its cleanliness. The exemption probably arises from the direct and intended sanitary character of the Jewish religious observances.

THE SMITHFIELD MARKET NUISANCE.—On Monday afternoon, as the corpse of Mr. Gavin, late of Lavies-street, Islington, was being conveyed for interment in the Bunhill fields burial-ground, when the bearers were in the act of crossing the City-road, near the Angel, a drove of oxen coming from Smithfield, pursued by a dog, rushed upon them; the coffin was hurled off the men's shoulders, and themselves prostrated; the mourners, chiefly females, fled shricking in affright. The corpse, in consequence of this indecent treatment, had to be conveyed to a neighbouring undertaker's, and one of the bearers was so seriously injured as to be unable to proceed.—*Globe*.

THE BRITISH ASSOCIATION.—The first general meeting of the members of this Association was held on Wednesday week, in the Town-hall; the Rev. Professor Robinson in the chair, who delivered an interesting speech in which he adverted to the progress of the Association. The Bishop of Oxford afterwards addressed the meeting. On Thursday morning the various sections met at the Free Grammar School, the Philosophical Institution, and the Queen's Hospital. They were presided over by Mr. Hopkins, F.R.S., Sir W. Harris, the Dean of Ely, Professor Stevelly, Mr. Willis, Dr. Piercey, Professor Apjohn, Professor Phillips, Sir C. Lyell, Sir R. A. Murchison, Sir D. Brewster, Lord Wrottesley, Sir H. F. De la Beche, the Dean of Westminster, and others distinguished in the walks of science.

SECTION A.—MATHEMATICAL AND PHYSICAL SCIENCE.—Mr. Ronald's General Report of proceedings at and in relation to the Kew Observatory during the last year. Mr. Birt: Report on the discussion of the electrical observations at the Kew Observatory. Mr. Grover: On the orbit of the magnetic pole, and on the evidences of a direct attraction of the needle by the two isodynamic poles. Professor Chevallier: On a rainbow seen after actual sunset. Mr. Twining: On teaching perspective by models. Rev. Professor Powell: On luminous meteors.

SECTION B.—CHEMISTRY, &c.—Dr. Scoffern: On the combined use of the basic acetates of lead and sulphurous acid in the colonial manufacture and the refining of sugar. Dr. Wilson: On the presence of fluorine in the waters of the Frith of Clyde, Frith of Forth, and the German Ocean. Mr. Rinman: On phosphorous, as producing cold-short iron. Mr. Ward: On the comparative cost of working various voltaic arrangements.

SECTION C.—GEOLOGY AND PHYSICAL GEOGRAPHY.—Mr. J. B. Jukes: On the general relations of the new red sand-stone, the coal measures, and the Silurian rocks of the South Staffordshire coal-field. Mr. S. H. Blackwell: On the igneous rocks of the South Staffordshire coal field. Mr. S. H. Blackwell: On the faults traversing the South Staffordshire coal-field. Mr. Isaac Lea: On the discovery of reptilian footprints in the old red sandstone near Pottsville, Philadelphia.

SECTION D.—NATURAL HISTORY, INCLUDING PHYSIOLOGY.—Professor Daubeny.—Report on the action of carbonic acid on plants allied to the fossil remains found in the coal formation.

SECTION F.—STATISTICS.—James Haywood, Esq., M.P., F.R.S.—To read a paper of Mr. Paton's on the sanitary condition of Darwen; G. R. Porter, Esq., F.R.S.: On the agricultural statistics of Ireland; and Professor Hancock: On the use to be made of the Ordnance survey to statistics in the registration of judgments and deeds in Ireland.

SECTION G.—MECHANICS.—Mr. Roberts: On a method of supplying the boilers of steam engines with water. Mr. Wishaw: On a chain pipe for subaqueous telegraphs. Mr. Roberts: On an eccentric gauge for wire, sheet metal, &c., also, on means for winding clockwork by the agency of the tide. Mr. Smith: On the superiority of Macadamized roads for the streets of large towns. And Mr. Heaton: On the causes and means of prevention of the oscillation of wheels of locomotive engines.

On Monday, Sir David Brewster was elected President for the ensuing year, and Edinburgh fixed upon for the next meeting of the Association.

The concluding General Meeting of the Members of the Association was held in the Town-hall on Wednesday. At a meeting of the Committee, held in King Edward's School, in the morning, Lord Dunfermline was elected a Vice-President. Colonel Sabine, the General Secretary, proceeded to read a long list of recommendations, by the General Committee, which were duly adopted. Professor Phillips, the Assistant-Secretary, next read a short Report, from which it appeared, that during the present meeting of the Association, there had been present, old life members, 277; old annual, 94; new life members, 11; new annual, 32; associates, 439; ladies, 237; and foreigners who had arrived by railway, 32: total, 1,122 persons; from whom had been received, 951*l.* 5s. 9d. These numbers had only been exceeded twice at any meeting of the Association which had been held since they assembled in Birmingham ten years ago. The President, in an eloquent address, expressed the thanks of the Association to the Mayor and various local authorities of Birmingham. The meeting had been eminently successful. Sir R. I. Murchison moved a vote of thanks to the President, which was seconded by the Mayor of Birmingham, and carried unanimously. The meeting was afterwards addressed by Lord Wrottesley, Dr. Buckland (the Dean of Westminster), and, finally, the meeting of the Association for 1849 was dissolved between five and six o'clock.

MORTALITY TABLE,

(Metropolis.)

For the Week ending Saturday, Sept. 15, 1849.

CAUSES OF DEATH.	Total.	Average of Five Summers.
ALL CAUSES	2865	1008
SPECIFIED CAUSES	2859	1005
Zymotic (or Epidemic, Endemic, and Contagious) Diseases	2159	302
SPORADIC DISEASES:		
Dropsy, Cancer and other Diseases of uncertain or variable seat	40	41
Tubercular Diseases	170	190
Diseases of the brain, Spinal Marrow, Nerves, and Senses	115	119
Diseases of the Heart and Blood vessels	20	29
Diseases of the Lungs, and of the other Organs of Respiration	76	81
Diseases of the Stomach, Liver, and other Organs of Digestion	67	76
Diseases of the Kidneys, &c.	14	11
Childbirth, Diseases of the Uterus, &c.	8	7
Rheumatism, Diseases of the Bones, Joints, &c.	3	7
Diseases of the Skin, Cellular Tissue, &c.	3	2
Malformations	5	3
Premature Birth and Debility	46	22
Atrophy	41	25
Age	42	43
Sudden	17	8
Violence, Privation, Cold, and Intemperance	33	36
Causes not Specified	6	3

The following is the number of Deaths occurring from some of the more important special causes:—

Apoplexy	20	Heart	18	Phthisis	97
Bronchitis ...	22	Hooping-cough	35	Pneumonia ..	40
Cholera.........	1682	Hydrocephalus	39	Scarlatina	24
Childbirth	6	Influenza	1	Small-pox	9
Convulsions...	81	Liver	13	Stomach	6
Diarrhœa	280	Lungs	7	Teething	15
Dropsy		Measles	15	Typhus	66
Erysipelas		Paralysis	15	Uterus	2

BIRTHS AND DEATHS.

	Births.	Deaths.	Deaths over Births.
Males	663	1351	688
Females	639	1514	875
Total......	1302	2865	1572

METEOROLOGY OF THE WEEK.

Day.	Mean of Barometer.	Mean of Thermometer. Dry.	Ditto. Dew Point.	Difference between the Mean Temperature of the day and the same day on an average of 7 years.	General Direction of Wind. A.M.	General Direction of Wind. P.M.	Amount of Horizontal Movement of the Air. Miles.	Rain in Inches.	Electricity.*
Sunday	29·600	57·9	47·5	−1·6	Calm.	S.W.	30	0·00	P. and tension variable.
Monday......	19·253	60·7	55·9	+0·9	S.W.	S.	40	0·00	P. & tension moderate between noon and 3 pm.
Tuesday......	28·998	57·6	49·2	−2·3	S.S.W.	S.W.	60	0·05	P. and tension weak.
Wednesday.	28·914	53·7	47·5	−9·2	S.W.	S.	130	0·44	P. and tension variable.
Thursday ...	29·440	54·6	48·6	−5·2	S.W. & W.	N.W.	205	0·14	P. and tension weak at 9 a.m.
Friday	30·014	53·7	47·4	−3·0	W.S.W.	W.S.W.	30	0·00	P and tension variable from 3 p.m.
Saturday ...	39·032	57·3	48·2	−2·0	W.	S.	15	0·00	P & tension strong between noon & 9 p.m.

* In this Column, A. stands for Active; N. for Negative; and P. for Positive.

TO CORRESPONDENTS.

"Antiquarian."—We cannot inform our Correspondent where he may obtain an English translation of Hippocrates' Treatise "De Ærlbus, Aquis et Locis." We believe there exists such a translation, which was made about a century ago. There is also a French version.

"M.B."—Ptyalism may be produced by other medicines than mercury. This affection has been known to arise from the use of some of the preparations of copper, arsenic, antimony, and gold. Dr. Hawkins, we believe, mentions a case in which salivation arose from the frequent administration of small doses of castor-oil.

"J. G., Nottingham."—A very useful amalgam for stopping decayed teeth is made by rubbing a small quantity of mercury in a glass mortar, with some precipitate of silver, till they unite and form a paste, which is then pressed through a piece of wash-leather, to remove as much of the mercury as possible. This paste is again rubbed in the mortar prior to its being used. A plug formed with this amalgam hardens in a few hours.

"A Constant Reader."—The active principle of Wourali poison is strychnia.

"Studens."—The density of urine is easily ascertained by the urinometer, originally suggested by Dr. Prout. The scale is divided into sixty degrees, the zero being the point at which it floats in distilled water. The numbers on the scale added to 1000, the assumed specific gravity of water, give the specific gravities at the respective points.

"A Surgeon."—The transparent isinglass plaster is made by spreading a solution of isinglass on the cæcum of an ox prepared expressly for the purpose. This membrane is stretched over the surface of a flat deal board, and kept tight by nails at the edges. When the membrane has dried, the solution of isinglass is brushed over it with a flat varnishing brush. The coating is allowed to dry spontaneously, and then another is applied. Four or five coats are thus successively laid on, changing the direction of the brush each time, and using rather a thinner gelatinous solution for the last coat than for those preceding. When a sufficient thickness of isinglass has been formed, the membrane is turned over on the board, so as to bring the uncoated surface upwards, and a layer coat of drying oil is to be applied on this side.

"Cambrian."—Candidates for the degree of Bachelor of Medicine in the University of London, are required to have been engaged during four years in their professional studies, at one or more of the institutions or schools recognized by the University, to have spent one year at least of the four in one or more of the recognized institutions or schools of the United Kingdom, and to pass two examinations. Practitioners, however, who have been admitted, prior to 1840, members of one of the legally constituted bodies for licensing in medicine or surgery, or who have served previously to 1840 as surgeons or assistant-surgeons in the army, navy, or East India Company's service, are eligible to examination.

"Chemicus."—The Pharmaceutical Society is incorporated by Royal charter. 2. It has for its object the elevation of the standard of education of chemists and druggists.

"A General Practitioner."—The diploma of the Faculty of Physicians and Surgeons of Glasgow confers no legal title to practice medicine in England.

"Gregorius."—The discovery of the spontaneous entrance of air into a wounded vein is comparatively of recent origin. M. Amussat was, we believe, the first who actually demonstrated the fact.

"Scotus."—The interior of an abscess appears to be both a secreting and an absorbing surface.

"J. J. N."—When morphia is contaminated with narcotine it is separated, either by alkalies, such as potash or lime, which dissolve the morphia and leave the narcotine, or by converting the mixture into a hydrochlorate and crystallising. The whole of the narcotine remains in the liquor.

"Ops."—Light is polarized by reflection from many substances, provided the light is incident at a certain angle peculiar to each surface, and which is called the polarizing angle.

"J. R. S" is thanked for his suggestion.

"Mr. Churche's" "Theory of the Origin and Propagation of Cholera" is declined.

"Celsus."—It is a most efficient preparation.

"L. M., Salisbury."—Not without examination.

"Amicus."—Yes, in 1817. Cholera, however, has been supposed to be described in the medical writings of the Hindoos, some of which are of great antiquity.

"D."—The electric fluid appears to act fatally by producing a violent shock to the brain and nervous system.

"Omicron."—1. Every medical practitioner who signs a certificate of lunacy must specify facts upon which his opinion is founded, and whether they are derived from his own observation or from the opinion of others. 2. There must be a separate visit, a separate personal examination, and a separate medical certificate.

"Truth."—1. In a state of health it is not unusual. 2. Morality would suggest the first means. 3. In all probability.

"Mr. Lamplough's" communication can only be inserted as an advertisement.

"R. W."—Calomel has been found useful, and afterwards the remedy mentioned. The head of the worm must be ejected before a cure is accomplished.

"Mr. Jno Cook, Morriston, near Swansea."—The fault does not rest with us, but with the author, from whom we are unable at present to obtain copy.

"X. Y. Z., St. George's Hospital."—We cannot give any information in reference to the Medical Club referred to; neither can we say who was the leading counsel for the prosecution in Rush's trial.

The letter of "Rusticus" was in type last week, but from a press of matter was not inserted. It will be found in the present number.

"M.R.C.S."—The cholera proceeded westward by way of the Persian Gulf along the western shore of the Caspian. The disease advanced up the Danube to Vienna. It appeared in Berlin, 1831, by way of Riga and Stettin. It reached Hamburgh early in October of the same year, and about the 20th cholera appeared in Sunderland, supposed to have been brought there by an infected vessel from Hamburgh.

"Seneca" is informed that his communication with his private note has been transmitted to our Edinburgh correspondent.

"Mr. Cheyne" has our thanks.

"T. H."—(1) The disease is certainly amenable to medical treatment, and any respectable practitioner may be consulted with advantage. Quacks should, by all means, be avoided. (2) We know nothing of the person alluded to.

"A Visitor to Deptford."—Morrison Secundus may be a very important person in his own neighbourhood, but he must attain greater eminence before we can notice him in the columns of the "Medical Times."

The paragraph sent from the Gutta Percha Company must, if inserted, be paid for as an Advertisement.

"Chirurgus," Bristol, is in type.

THE RULES AND REGULATIONS OF EXAMINING MEDICAL BODIES IN ENGLAND, SCOTLAND, AND IRELAND.

ENGLAND.

UNIVERSITY OF OXFORD.

Full term is understood to begin on the first day of the week after the congregation has been held; so that, if the congregation be held on the Monday, the Sunday after is considered the first day of full term.

According to the lately-altered statute respecting medical degrees, a candidate for the degree of Bachelor in Medicine, before he can be admitted to examination for that degree, must have kept four whole years, or sixteen terms, in the University, in like manner as is required by candidates for a degree in arts (a); must have passed the examination for the degree of bachelor in arts; and subsequently to that examination must have studied medicine during three whole years, or twelve terms; and must also have completed seven years, or twenty-eight terms, from his matriculation.

The medical examination takes place only once in the course of the year, namely, in the second week of full Trinity term, commencing usually on the *second Tuesday* after Trinity Sunday. The candidates are examined, principally *vivâ voce*, but partly in writing, in the theory and practice of medicine, in anatomy, physiology, pathology, and materia medica; and also in chemistry and botany, as far as they elucidate the art of medicine. He is required to be conversant with the entire works of Aretæus and Celsus; the aphorisms and epidemics of Hippocrates; and that portion of Galen's writings entitled, "De Usu Partium;" in two, at least, of which authors, the statute directs that the examiners fail not to test the candidate's attainments. He must send, fourteen days before the day of examination, certificates of three years' attendance on the medical practice of a hospital, with the usual lectures.

Certificates are required for two courses of anatomy and physiology, each extending from October till the following April or May; two courses on the theory and practice of medicine, each course of the same extent; one course in materia medica; one course in botany; one course in chemistry, provided the course extend through the usual winter session, otherwise two courses will be required.

A candidate for the degree of doctor in medicine must have pursued the study of medicine during three years after he has graduated as bachelor in medicine, and must give, at least, a fortnight's previous notice of his intention to the professor of medicine, at the same time submitting to approbation a subject for a medical dissertation, which dissertation must be read in the public schools of the University within a few days of taking the degree of M.D., and delivered to the Professor immediately after it has been read. No graduate in medicine from another University can be incorporated at Oxford unless he produce testimonials by which it may clearly appear that he has kept by residence terms equal to those required to be so kept in this University; he has completed all the exercises prescribed by the University from which he migrates for the degree of bachelor of arts; and shall have previously undergone the medical examination above described; and shall have fulfilled all the other conditions of the present statute. The fees for a bachelor of medicine are 23*l.*; for a doctor in medicine, 40*l.*

The University of Oxford is in possession of the Bodleian Library (Librarian, B. Bandinel, D.D.); of the Radclyffe Library (Librarian, Dr. Kidd); of the Ashmolean Museum (Keeper, P. B. Duncan, M.A.); and of the Botanic Gardens, founded by the Earl of Derby in 1632. All these are open to students under certain restrictions.

Radclyffe Travelling Fellows.—Dr. Radclyffe left by will an endowment of 600*l.* per annum, to be paid to two persons, to be chosen out of the University of Oxford, when they are M.A., entered on the study of physic for their maintenance for ten years, and no longer, the half of which time, at least, they are to travel in parts beyond sea, for their better improvement. In case of vacancy by death, or at the expiration of the ten years, a new election is to take place within six months.

UNIVERSITY OF CAMBRIDGE.

There is a course of fifty lectures delivered in this University on the principles of pathology and the practice of physic; 5*l.* 5*s.* first course, afterwards gratis. The Professor of Chemistry delivers thirty lectures, on the general principles of that science, during Lent term, and twenty lectures, principally on organic chemistry, during Easter term. Lectures on experimental philosophy, to illustrate the laws of hydrostatics, pneumatics, and optics, with particular reference to the mathematical theories of light and sound, are delivered in Easter term. About fifty lectures on anatomy are delivered in Michaelmas and Lent terms. The terms of attendance are 5*l.* 5*s.* for each of two courses, afterwards gratis. The pupils have the opportunity of dissecting in private. Botanical lectures are given during the Easter term, with herborising excursions occasionally. Lectures on natural and experimental philosophy are delivered during the Michaelmas term; the subjects being statics, dynamics, and mechanism, with their practical illustrations: first course, 3*l.* 3*s.*; second, 2*l.* 2*s.*; afterwards gratis. The Downing Professor of Physic delivers a course of fifty lectures on some medical subject. A certificate of attendance is required of persons proceeding to the degree of M.B. Lectures are also delivered on crystallography and mineralogy during the Lent term. Addenbrooke's Hospital, which is connected with the University, is recognised by the Colleges of Physicians and Surgeons, and by Apothecaries' Hall. It contains 100 beds, and has a department reserved for cases of midwifery.

A student, before he can become a Bachelor of Physic, must have entered on his sixth year, computed from the date of his first admission at the University, have resided nine terms, and have passed the previous examination.

A Bachelor of Arts may become a Bachelor of Physic after having entered on his sixth year, computed from the date of his first admission at the University, provided that one year at least has intervened between his final determination in arts and his admission to the degree of Bachelor of Physic.

The exercises for this degree are one act and one opponency.

Candidates for the degree of bachelor of physic must, in addition to the examination by the Regius Professor of Physic, be examined by the Professors of Anatomy, Chemistry, and Botany, and by the Downing Professor of Medicine. This examination must not take place before the fifth year after admission. They must have diligently attended the lectures of the Regius Professor of Physic for two terms, and must bring to him certificates of examination by the above professors, and of attendance on their lectures, in case the course of lectures of the Professor of Botany consist of not less than twenty lectures, and the courses of lectures of the Professors of Anatomy and Chemistry, and of the Downing Professor of Medicine, of not less than fifty lectures each. They must also deliver to the Regius Professor of Physic certificates of having been diligently employed in attendance on medical lectures, and the practice of some well-known hospital, for two years, or for as long a time as they have been absent from the University during their undergraduateship. Fee, 20*l.* 16*s.*

A license *ad practicandum in medicina* may be granted to a bachelor of physic in the terms subsequent to that in which he has taken the degree, or to a master of arts of two years' standing.

Candidates for a license *ad practicandum in medicina*, being previously bachelors of physic, are required to produce to the Regius Professor of Physic certificates of their having attended on hospital practice for three years, exclusive of the nine terms which they kept by residence for the degree of bachelor of physic, and of their having attended lectures on the following subjects:—Practice of physic and pathology, anatomy and physiology, chemistry, botany, medical jurisprudence, materia medica and pharmacy, principles of surgery, principles of midwifery, practical anatomy, for two seasons.

Candidates for a license *ad practicandum in medicina*, being previously Masters of Arts, are required to bring satisfactory evidence to the Regius Professor of Physic of their having been employed in the study of physic for five years after they became Bachelors of Arts; and to produce to him certificates of their having attended on hospital practice for three of the said five years, and of their having attended lectures on the subjects before mentioned.

Every candidate for a license *ad practicandum in medicinâ* is required to pass an examination to the satisfaction of the Regius Professor of Physic, the Professor of Anatomy, the Downing Professor of Medicine, and a Doctor of Physic, to be nominated by the Vice-Chancellor, and approved by the Senate, at the first congregation after the 10th of October in each year.

There are two such examinations in every year: one in the week immediately preceding that in which the division of the Michaelmas term falls; the other in the week immediately preceding that in which the division of the Easter term falls.

A candidate for a license *ad practicandum in medicina*, being previously Bachelor of Physic, cannot be examined for the said license until the examination which shall occur next but one after his having passed the examination required for the degree of Bachelor of Physic. Fee, 11*l.* 0*s.*

M.D.—The degree of Doctor of Physic is granted to a Bachelor of Physic of five years, or to a Master of Arts of seven years' standing.

The exercises for this degree are two acts and one opponency.

Every candidate for the degree of Doctor of Physic, who has not previously obtained a license *ad practicandum in medicina*, is required to produce to the Regius Professor of Physic the same certificates, and pass the same examination as are required in the case of candidates for a license *ad practicandum in medicina*. Fee, 11*l.* 12*s.*

The University possesses an Anatomical Museum, to which has been added the valuable collection of the late Dr. Macartney, the Fitzwilliam, Mesman, Mineralogy, and Geological Museums, an extensive Botanic Garden, and the University Library. To all these the students have access.

UNIVERSITY OF LONDON.

Examinations for the Degree of Bachelor of Medicine.—Candidates for the degree of Bachelor of Medicine shall be required—1. To have been engaged during four years in their professional studies at one or more of the Institutions or schools recognised by this University. 2. To have spent one year at least of the four in one or more of the recognised Institutions or schools in the United Kingdom. 3. To pass two examinations.

The first examination shall take place once a year, and commence on the first Monday in August. No candidate shall be admitted to this examination unless he have produced certificates to the following effect:—1. Of having completed his nineteenth year. 2. Of having taken a degree in arts in this University, or in a university the degrees granted by which are recognised by the Senate of this University; or of having passed the matriculation examination. 3. Of having been a student during two years at one or more of the medical Institutions or schools recognised by this University, subsequently to having taken a degree in arts, or passed the matriculation examination. 4. Of having attended a course of lectures on each of four of the subjects in the following list:—Descriptive and Surgical Anatomy, General Anatomy and Physiology, Comparative Anatomy, Pathological Anatomy, Chemistry, Botany, Materia Medica and Pharmacy, General Pathology, General Therapeutics, Forensic [illegible] Midwifery and Diseases peculiar [illegible] Surgery, Medicine. [illegible]

(a) That is, he must be of sixteen terms' standing, and have actually resided in the University twelve terms.

[illegible]. 6. Of having attended a course of Practical Chemistry, comprehending practical exercises in conducting the more important processes of general and pharmaceutical chemistry; in applying tests for discovering the adulteration of articles of the materia medica, and the presence and nature of poisons; and in the examination of mineral waters, animal secretions, urinary deposits, calculi, &c. 7. Of having attended to practical pharmacy during a sufficient length of time to enable him to acquire a practical knowledge in the preparation of medicines.

These certificates must be transmitted to the registrar at least fourteen days before the commencement of the examination. The fee for this examination is 5*l*. No candidate can be admitted to the examination unless he have previously paid this fee to the registrar; and, if he fail to pass the examination, the fee will be returned to him.

The candidates are examined in the following subjects:—Anatomy, Physiology, Chemistry, Structural and Physiological Botany, Materia Medica, and Pharmacy.

The examinations are conducted in the following order:—Morning, 10 to 1: Monday, Anatomy and Physiology, by printed papers; Tuesday, Chemistry, by experiment and printed papers. Afternoon, 3 to 6: Monday, Anatomy and Physiology, by printed papers; Tuesday, Botany, Materia Medica, and Pharmacy, by printed papers. To commence on Friday at 10: Chemistry, Materia Medica, and Pharmacy, by *vivâ voce*, and demonstration from specimens. To commence on Monday, in the following week, at 10: anatomy and physiology, by *vivâ voce* demonstration from preparations, and dissection.

On the Wednesday morning in the week following the commencement of the examination, the Examiners will arrange in two divisions, each in alphabetical order, such of the candidates as have passed; and a pass certificate signed by the Registrar, will be delivered to each candidate. Such candidates only as in the opinion of the Examiners are admissible to the examination for honours shall be placed in the first division.

Examination for Honours.—Any candidate who has been placed in the first division at the first examination may be examined for honours in any or all of the following subjects:—Anatomy and physiology, (candidates may illustrate their answers by sketching the parts they describe,) chemistry, materia medica, and pharmaceutical chemistry.

These examinations take place in the week following the commencement of the first examination. They are conducted by means of printed papers; but the Examiners are not precluded from putting *vivâ voce* questions upon the written answers of the candidates when they appear to require explanation. The examinations for honours are conducted in the following order:—Morning 10 to 1: Thursday, Anatomy and Physiology: Friday, Chemistry. Afternoon, 3 to 6: Thursday, Anatomy and Physiology; Friday, Materia Medica and Pharmaceutical Chemistry.

If, in the opinion of the Examiners, sufficient merit be evinced, the candidate who shall distinguish himself the most in Anatomy and Physiology, the candidate who shall distinguish himself most in Chemistry, and the candidate who shall distinguish himself the most in Materia Medica and Pharmaceutical Chemistry, shall each receive an exhibition of thirty pounds per annum for the next two years. Under the same circumstances, the first and second candidates in each subject shall each receive a gold medal of the value of five pounds.

Second Examination.—The second examination takes place once a year, and commences on the first Monday in November. No candidate can be admitted to this examination within two academical years of the time of his passing the first examination, nor unless he have produced certificates to the following effect:—1. Of having passed the first examination. 2. Of having, subsequently to having passed the first examination, attended a course of lectures on each of two of the subjects comprehended in the foregoing list, and for which the candidate had not presented certificates at the first examination. 3. Of having, subsequently to having passed the first examination, dissected during six months. 4. Of having conducted at least six labours. (Certificates on this subject will be received from any legally qualified practitioner in medicine.) 5. Of having attended the surgical practice of a recognised hospital or hospitals during twelve months, and lectures on clinical surgery. 6. Of having attended the medical practice of a recognised hospital or hospitals during other twelve months, and lectures on clinical medicine. 7. Of having, subsequently to the completion of his attendance on surgical and medical hospital practice, attended to practical medicine, in a recognised hospital, infirmary, or dispensary, during six months. (Certificates on this subject will be received from any legally qualified practitioner having the care of the poor of a parish.) The candidate must also produce a certificate of moral character from a teacher in the last school or institution at which he has studied, as far as the teacher's opportunity of knowledge has extended.

The certificates must be transmitted to the registrar at least fourteen days before the examination begins. The fee for this examination is five pounds.

Candidates are examined in the following subjects:—Physiology, (the papers in Physiology including questions in Comparative Anatomy,) General Pathology, General Therapeutics, Hygiene, Surgery, Medicine, Midwifery, Forensic Medicine. The examination is conducted in the following order:—First week. By printed papers. Morning, 10 to 1: Monday, Physiology; Tuesday, Surgery; Wednesday, Midwifery. Afternoon, 3 to 6; Monday, General Pathology, General Therapeutics, and Hygiene; Tuesday, Medicine; Wednesday, Forensic Medicine. Second Week. By *vivâ voce* interrogations. To commence on Monday morning at 10.

On the Monday morning in the following week the examiners will arrange in two divisions, each in alphabetical order, such of the candidates as have passed; and a certificate under the seal of the University, and signed by the Chancellor, will be delivered to each candidate. Such candidates only as in the opinion of the Examiners are admissible to the examination for honours will be placed in the first division.

Examination for Honours.—Any candidate who has been placed in the first division at the second examination, and has produced a certificate showing that he has not completed his twenty-fifth year, may be examined for honours in any or all of the following subjects:—Physiology and Comparative Anatomy, (candidates may illustrate their answers by sketching the parts they describe,) Surgery, Medicine, Midwifery, Structural, and Physiological Botany.

The examination for honours will take place in the week following the second examination. It will be conducted by means of printed papers; but the examiners are not precluded from putting *vivâ voce* questions upon the written answers of the candidates when they appear to require explanation. The examination is conducted in the following order:—Morning, 10 to 1; Tuesday, Physiology and Comparative Anatomy; Wednesday, Surgery; Thursday, Medicine; Friday, Midwifery; Afternoon, 3 to 6; Tuesday, Physiology and Comparative Anatomy; Wednesday, Surgery; Thursday, Medicine; Friday, Structural and Physiological Botany.

If, in the opinion of the Examiners, sufficient merit be evinced, the candidate who shall distinguish himself the most in Physiology and Comparative Anatomy, the candidate who shall distinguish himself the most in Surgery, and the candidate who shall distinguish himself the most in Medicine, shall each receive an exhibition of 50*l*. per annum for the next two years, with the style of University Medical Scholar. Under the same circumstances, the first and second candidate in each of the preceding subjects shall each receive a gold medal of the value of 5*l*. Under the same circumstances, the candidate who shall distinguish himself the most in midwifery, and the candidate who shall distinguish himself the most in structural and physiological botany, shall each receive a gold medal of the value of 5*l*.

Examination for the Degree of Doctor of Medicine.—The examination for the Degree of Doctor of Medicine takes place once a year, and commences on the fourth Monday in November. No candidate can be admitted to this examination unless he have produced certificates to the following effect:—1. Of having taken the degree of Bachelor of Medicine in this University, or a degree in medicine or in surgery at a university, the degrees granted by which are recognised by the Senate of this University. Those candidates who have not taken the degree in this University shall produce a certificate of having completed their twenty third year. 2. Of having attended, subsequently to having taken one of the above degrees in medicine, (*a*) to clinical or practical medicine during two years in a hospital or medical institution recognised by this University; (*b*) or to clinical or practical medicine during one year in a hospital or medical institution recognised by this University, and of having been engaged during three years in the practice of his profession; (*c*) or, if he have taken the degree of Bachelor of Medicine in this University, of having been engaged during five years in the practice of his profession. (One year of attendance on clinical or practical medicine, or two years of practice, will be dispensed with in the case of those candidates who, at the second examination, have been placed in the first division.) 3. A moral character, signed by two persons of respectability.

These certificates must be transmitted to the registrar at least fourteen days before the examination begins. The fee for the Degree of Bachelor of Medicine is 10*l*.

Candidates are examined in the following subjects:—Elements of Intellectual Philosophy, Logic, and Moral Philosophy; Medicine. The examinations are conducted in the following order:—By printed papers, morning, 10 to 1: Monday, Elements of Intellectual Philosophy, Logic, and Moral Philosophy. (Candidates who have taken a Degree in Arts in this University, or in a University the degrees granted by which are recognised by the Senate of this University, are exempted from this part of the examination. The Degrees in Arts of all universities in the United Kingdom are recognised by the senate for this purpose.) Tuesday, Medicine. Afternoon, 3 to 6; Monday, a Commentary on a case in Medicine, Surgery, or Midwifery, at the option of the candidate. Tuesday, Medicine, by *vivâ voce* interrogation. Friday morning, at 10, examination on the answers to the printed papers, and on the commentaries; and the examination for a certificate of Special Proficiency in Medicine, Surgery, or Midwifery, as determined by the candidate's choice of the case for commentary.

On the Monday morning in the following week the Examiners will arrange in two divisions, each in alphabetical order, such of the candidates as have passed; and a certificate under the seal of the university, and signed by the chancellor, will be delivered to each candidate. Such candidates only as, in the opinion of the Examiners, are admissible to the examination for honours, will be placed in the first division. If, in the opinion of the Examiners, sufficient merit be evinced, the author of the best Commentary on the Case in Medicine, the author of the best Commentary on the Case in Surgery, and the author of the best Commentary on the Case in Midwifery, will each receive a gold medal of the value of 5*l*. Any candidate may present a thesis on a subject of his own choice. If, in the opinion of the Examiners, sufficient merit be evinced, a gold medal, of the value of 10*l*., will be given to the author of the best thesis. The Examiners are not precluded from examining the author on the subject of his thesis.

Examination for Honours.—Any candidate who has been placed in the first division may be examined for honours in any or all of the following subjects:—Surgery, Medicine, Midwifery. The examinations take place in the week following. They are conducted by means of printed papers; but the examiners are not precluded from putting *vivâ voce* questions upon the written answers of the candidates, when they appear to require explanation.

The examinations for honours are conducted

in the following order:—Morning, 10 to 1: Tuesday, Surgery; Wednesday, Medicine; Thursday, Midwifery. Afternoon, 3 to 6: Tuesday, Surgery; Wednesday, Medicine; Thursday, Midwifery.

If, in the opinion of the Examiners, sufficient merit be evinced, the first candidate in each subject will each receive a gold medal of the value of 5*l*.

Institutions and Schools.—No medical institution or school is recognised by the Senate of this University, which does not possess ample means of illustrating the instruction given at it. *Forms of Certificates.*—The teacher must certify for—*Lectures,*—That in the year 18 , the pupil attended . . . his course of instruction on . . . . which commenced on . . . . and terminated at . . . . and which consisted of . . . . . . lectures and . . . examinations. *Practical Anatomy,*—That from . . to . . the pupil dissected . . . . . under his superintendence. *Practical Chemistry,*—That the pupil operated . . . . during his course of Practical chemistry, which consisted of . . . lessons. *Practical Pharmacy,*—That the pupil prepared . . . medicines under his superintendence from . . . . to . . . . *Clinical Instruction in Surgery,*—That the pupil attended . . . . . the surgical practice of this hospital, and the course of lectures on clinical surgery, consisting of . . . . lectures, from to . . . . *Clinical Instruction in Medicine,*—That the pupil attended . . . . the medical practice of this hospital, and the course of lectures on clinical medicine, consisting of . . . . . lectures from . . . . to . . . . *Practical Medicine,*—That the pupil attended to practical medicine at . . . . . and was intrusted with the treatment of patients under . . . . . superintendence, from . . . . . to . . . . (Certificates on this subject will be received from any legally qualified practitioner, having the care of the poor of a parish.) *Practical Midwifery,*—That the pupil conducted . . . . labours under his superintendence. (Any legally-qualified practitioner shall be competent to give this certificate.)

Regulations relating to Students who commenced their Medical Studies in or before January, 1840.

Degree of Bachelor of Medicine.—Candidates, who commenced their professional studies in or before January, 1840, are admitted to the first examination for the degree of Bachelor of Medicine on producing certificates to the following effect:—1. Of having been engaged during two years in their professional studies. 2. Of having attended a course of lectures on each of four of the subjects comprehended in the former list. 3. Of having dissected during nine months. 4. Of having attended to practical pharmacy during a sufficient length of time to enable them to acquire a practical knowledge in the preparation of medicines.

Candidates who commenced their professional studies in or before January, 1840, are admitted to the second examination for the degree of Bachelor of Medicine, on producing certificates to the following effect:—1. Of having been engaged during four years in their professional studies. 2. Of having passed the first examination. 3. Of having attended a course of lectures on each of two of the subjects comprehended in the former list. 4. Of having dissected during twelve months. 5. Of having attended to practical pharmacy during a sufficient length of time to enable the pupil to acquire a practical knowledge in the preparation of medicines. 6. Of having conducted at least six labours. 7. Of having attended the surgical practice of a recognised hospital or hospitals during twelve months. 8. Of having attended the medical practice of a recognised hospital or hospitals during other twelve months. 9. Of having completed the twenty-second year of their age. 10. Of moral character, from a teacher in the last school or institution at which they have studied, as far as the teacher's opportunity of knowledge has extended.

Candidates who have not taken a degree in Arts, or passed the Matriculation Examination in this University, will be required to translate a portion of "Celsus de re Medicâ."

Regulations relating to the Practitioners in Medicine or Surgery desirous of obtaining Degrees in Medicine.

Degree of Bachelor of Medicine.—Candidates are admitted to the two examinations for the degree of Bachelor of Medicine on producing certificates to the following effect:—1. Of having been admitted, prior to the year 1840, members of one of the legally constituted bodies in the United Kingdom for licensing practitioners in medicine or surgery, or of having served, previously to 1840, as surgeons, or assistant surgeons, in Her Majesty's Army, Ordnance, or Navy, or in the service of the Honourable the East India Company. 2. Of having received a part of their education at a recognised institution or school, as required by the charter of the University. 3. Of moral character, signed by two persons of respectability.

Candidates who have not taken a degree in Arts, or passed the matriculation examination in this University, will be required to translate a portion of "Celsus de re Medicâ."

Degree of Doctor of Medicine.—Candidates who have been engaged during five years in the practice of their profession may be admitted to the examination for this degree on producing certificates to the following effect:—1. Of having been engaged during five years in the practice of their profession. 2. Of having taken the degree of Bachelor of Medicine in this University.

Candidates who have not taken a degree in Arts, or passed the matriculation examination in this University, will be required to translate a portion of "Celsus de re Medicâ."

The regulations respecting the transmission of the certificates to the Registrar, the fees, the periods, and the mode of conducting the examinations, and the arrangement of the candidates after examination, are the same for all candidates for the same degree.

ROYAL COLLEGE OF PHYSICIANS, LONDON.

According to the regulations of this College, no one will be admitted a candidate for the licence, unless he shall have attained the age of six-and twenty, and shall present a certificate of good moral conduct. His medical education must comprise Anatomy, the Theory and Practice of Medicine, Forensic Medicine, Chemistry, Materia Medica, Natural History, (principally Botany,) Midwifery, and the principles of Surgery, and must extend over the period of five years. Practical Medicine must be studied for three years in a hospital containing at least 100 beds, and having a complete staff of physicians and surgeons. Those who have studied abroad, in addition to giving proof of five years' Medical education according to the usual course of study, are required to present testimonials of a twelvemonth's medical practice at any hospital in Great Britain, having the qualifications as above.

No one will be admitted as a licentiate (*Permissus*) who is accustomed to use any secret medicine or nostrum in the treatment of disease, unless previously to his first examination he make known to the President and Censors its composition and the manner in which it is employed. Every candidate must undergo three examinations, each conducted at different times, before the President and Censors in *comitia minora.* The first examination comprises Physiology, the second Pathology, and the third Therapeutics. After the first examination, the President may inquire of the candidate where he studied polite literature and the principles of science, and what honours he has obtained, whether in Philosophy, Arts, or Medicine, in order that the answers may be recorded by the Registrar. The candidate will also be examined in Greek works on medicine, to wit, Hippocrates, Galen, or Aretæus. Passages from the Aphorisms of Hippocrates or Galen will be brought forward during the first examination; and during the second and third, passages from Hippocrates, Galen, or Aretæus, which must be translated into Latin, and illustrated with a brief commentary. If the candidate be deficient in his knowledge of Greek, he will be required to translate parts of Celsus or Sydenham, or some other Latin work on medicine, into English. The examinations are conducted in Latin or English at the pleasure of the Censors.

Whenever a candidate has passed the prescribed examinations, and has been approved, he will be proposed at the next *comitium majus* (a meeting of the Fellows at large) to be admitted as a licentiate; and, if the majority present consent, he will be admitted accordingly. If, however, the candidate be rejected, he cannot present himself for re-examination for a twelvemonth.

Before the licentiate is admitted, he is required to plight his faith to the College according to a formula, pronounced by the President before the Fellows assembled in *comitium majus.*

If any one holding the license of the College practise pharmacy afterwards, or engage in merchandise, he is liable to expulsion; and any person practising medicine in London, or within seven miles thereof, without having previously obtained the collegiate licence, is to be admonished by letter to cease his practice until after he has passed the required examinations; and if he continues to practise, despite this admonition, then *legibus regni ch ... erit.*

Persons who have attained their fortieth year, seeking to become licentiates of the College, but whose medical education is not altogether in accordance with the regulations already stated, must present testimonials of professional knowledge and good moral conduct, and, if these are satisfactory, they will be admitted to examination the same as for licentiates in general.

The old regulation restricting the fellowship, as a matter of right, to the graduates of Oxford, Cambridge, and Trinity College, was repealed in the latter part of 1835; and after Easter, 1836, all candidates were declared to be admissible as licentiates only, from which class, when duly qualified, a certain number are to be annually elected Fellows in *comitia majora.* The advantage derived by graduates of the English Universities, and by the Irish graduate who possesses an *ad eundem* degree from an English University, is, that they are eligible a year after they have obtained the licence; the Scotch graduate, being M.A. or B.A., five years later. If the latter does not possess any degree in Arts, his eligibility for the fellowship does not occur until after the lapse of seven years. The Irish graduates who do not possess an *ad eundem* degree are not eligible for two years after they are licensed. The President and Censors propose the candidates for the fellowship, but the *comitia majora* may reject the proposition and choose their nominees. The election is by ballot.

The President of the College is *ex-officio* President of the Vaccine Board, a Trustee of the British and Hunterian Museum, Physician to the Queen, and an elector to the Tancred scholarships. The College has the power of recommending a physician to Christ Church, St. Thomas's, and St. Bartholomew's Hospitals; but, if the recommendation succeed, it is then required to pay an annual stipend of 30*l*. or 40*l* to the Physician. The College also appoints the Professor of Botany to the University of Oxford.

The examinations for the licence are conducted by the President and Censors. The periods at which they take place are Michaelmas, Christmas, Easter, and in the month of June. The new Censors are elected on the 24th of June, when the Harveian oration is delivered. The lectures are delivered in the early part of the year. These are about fifteen delivered: three Gulstonian, three Croonian, and three Lumleian, so called from the names of those who left endowments to the College for the purpose; and six lectures on Materia Medica. The Museum and Library are attached to the Institution, to which the Fellows and, by permission, their friends have access.

The President may each year propose one candidate for the licence, he being an M.D., but not otherwise eligible; and he may also name annually a licentiate of ten years' standing, for the fellowship; the fellows have also the power of proposing a licentiate of seven years' standing, who is thirty-

six years of age, for the fellowship; but this has been done so rarely as to be, in fact, obsolete.

The College fees are 56*l.* 17*s.* for the licence; the fellow pays in addition 1*l.* 1*s.* annually to the collegiate fund.

If any fellow or licentiate can be proved, to the satisfaction of the President and Censors, to have wilfully accused any other fellow or licentiate of professional ignorance, &c., unless it be before the legally constituted judges, he shall be fined 4*l.* for the first offence, and 8*l.* for the second; if he offend a third time, if a fellow, he shall be expelled, and if a licentiate, fined 10*l.* This last fine is to be enforced every time afterwards the licentiate shall so offend. If any fellow or licentiate shall offer his professional assistance to any patient whom he shall know to be under the care of another physician, whether fellow or licentiate, without having been called in to see the patient professionally, he shall be fined 40*s.*

If any fellow be proved to have made any arrangement with a druggist, to share with him the proceeds in his prescriptions, he shall be expelled; if a licentiate have entered into a similar arrangement, he shall be fined 10*l.* every time he shall so offend.

Every physician, whether fellow or licentiate, shall attach to each prescription which he writes, the day of the month, the name of the sick man, and his own initials. When a consultation takes place, it is to be carried on with modesty, not in the presence of the sick; and if any difference of opinion occurs, it is to be stated with prudence and moderation, so that it may not be noticed by the patient or the friends, but, if requisite, should be mentioned by the ordinary medical attendant. Whoever infringes these regulations will be fined 5*l.* by the President and Censors.

No fellow or licentiate may consult, in London or within seven miles thereof, with a physician who does not belong to the College, under a penalty of 5*l.*

All fines are to be paid immediately.

The President and Court of the College have the power of committing individuals contemning their authority to Newgate. This power has been exercised by the Court, but not of late years.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

Regulations for Candidates for the Fellowship of the Royal College of Surgeons of England.

1. That every candidate for the fellowship, whether a member of the College or not, shall produce certificates satisfactory to the Court of Examiners

That he is twenty-five years of age.

That he is (if found qualified upon his examination) a fit and proper person to be admitted to the fellowship, and the certificate of which shall be signed by three fellows.

That he has attained a competent knowledge of the Greek, Latin, and French languages, and of the elements of mathematics.

That he has been engaged for six years in the acquirement of Professional knowledge in recognised hospitals or schools of surgery and medicine within the United Kingdom of Great Britain and Ireland, or in foreign countries; and that three of such years, at least, have been passed in one or more of such recognised hospitals or schools in London.

That he has attended the surgical practice of a recognised hospital or hospitals during four years, and the medical practice of a recognised hospital or hospitals for one year.

That he has studied anatomy and physiology by attendance on lectures and demonstrations, and by dissections, during three winter sessions of not less than six months each, at one or more recognised school or schools.

That he has attended lectures on the theory and practice of medicine, and on clinical medicine, and also on the theory and practice of surgery, and on clinical surgery, during two sessions of six months each, at one or more recognised school or schools.

That he has attended one course of lectures on each of the following subjects, viz., chemistry, materia medica, midwifery, medical jurisprudence, and comparative anatomy, at one or more recognised school or schools; and that he has served the office of house-surgeon or dresser in a recognised hospital in the United Kingdom. Every such candidate (except in the case and instances hereinafter provided for to the contrary shall also present for examination Clinical Reports, with observations of six or more surgical cases taken by himself at a recognised hospital or recognised hospitals within the United Kingdom, with sufficient certificates of their authenticity and genuineness, and shall leave such reports at the College.

3. That as to any candidate who shall have taken the degree of bachelor of arts in an English university, and shall produce satisfactory evidence thereof, it shall, instead of the certificate or certificates that he has been engaged for six years in the acquirement of the professional knowledge as before mentioned, be sufficient for him to produce a satisfactory certificate or certificates that he has been engaged for five years in the acquirement of professional knowledge in recognised hospitals and schools of surgery and medicine within the United Kingdom, or in foreign countries, and that three of such years at least have been passed in one or more of the recognised hospitals or schools of London; and that it shall not be necessary for any candidate having so taken the degree of bachelor of arts to produce any certificate of his having acquired a competent knowledge of the Greek, Latin, and French languages, and of the elements of mathematics.

4. That upon the 1st day of January, 1850, or at any earlier period which may be thought proper, the Council shall, under such regulations, and for such time or period as to them shall seem proper (but always subject to removal at the pleasure of the Council), appoint three persons, and being, or not being, and either all, or in part, members of the College, as the Council shall think proper, for the purpose of examining persons intending to become candidates for the fellowship, and required to be examined in the Greek, Latin, and French languages, and in the elements of mathematics; and the said Council, from time to time after the first appointment of such persons for such purpose as aforesaid, and as often as shall be necessary, or to the said Council as shall seem proper in their behalf, shall appoint such other person or persons as to them shall seem fit and proper to succeed or supply the place or places of any person or persons previously appointed for such purpose; and that, from and after the first appointment of any such persons for the purpose of making such examination as aforesaid, no certificate of a candidate having competent knowledge of the Greek, Latin, and French languages, and of the elements of mathematics, shall be received or allowed by the Court of Examiners, except the certificate or certificates of the persons for the time being so appointed as aforesaid.

5. That all members of the College, future as well as present, shall be entitled to be admitted to the examination for the fellowship according to the foregoing bye-laws and ordinances.

6. That any person who shall have been a member of the College on the 14th day of September, 1844, shall, after the expiration of eight years from the date of his diploma, also be entitled to be admitted to the examination for the fellowship upon the production of a certificate, signed by three fellows, that he has been eight years in the practice of the profession of surgery, and that he is a fit and proper person to be admitted a fellow, if upon examination he shall be found qualified.

7. That any person who shall have become a member of the College after the said 14th day of September, 1844, shall, after the expiration of twelve years from the date of the diploma, also be entitled to be admitted to the examination for the fellowship, upon the production of a certificate signed by three fellows, that he has been for twelve years in the practice of the profession of surgery, that he is a fit and proper person to be admitted a fellow, if, upon examination, he shall be found qualified, and also if he have not taken the degree of Bachelor of Arts in an English university, of a certificate or certificates that he has a competent knowledge of the Greek, Latin, and French languages, and of the elements of mathematics.

Examination of Candidates for the Fellowship.

1. The examination for the fellowship shall be held three times in the year, at or within such periods as the Council shall from time to time determine.

2. Each candidate shall be examined on two days, either successive or at such an interval as the Court of Examiners may appoint.

3. The subjects for the first day's examination shall be anatomy and physiology; those of the second, pathology, therapeutics, and surgery.

4. The time allowed for examination each day shall be, from ten o'clock in the forenoon until five o'clock in the afternoon.

5. The examination shall be conducted in the following manner. Each candidate shall, upon going in for examination, have delivered to him a written or printed copy of such questions as shall have been previously determined upon by the Court of Examiners, and to which questions he shall give written answers, and which answers shall be considered by the Court of Examiners.

The Court may, however, if they should think fit, interrogate any candidate on any matters connected with the questions or answers. In the anatomical examination, the candidate shall also perform dissections and operations on the dead body in the presence of the Court of Examiners, or of such members thereof as may be deputed by the Court to superintend the same. Candidates whose qualifications shall be found insufficient shall not be allowed to present themselves a second time until after the expiration of one year from their first examination.

The Court of Examiners shall report in writing to the Council the names of such persons as they shall have found upon examination to be qualified for the fellowship.

*** Members of the College will pay ten guineas besides charges for status, and non members thirty guineas.

Regulations of the Council respecting the Professional Education of Candidates for the Diploma who commence their Studies before the year 1838.

I. Candidates will be required to bring proof— 1. Of being twenty two years of age. 2. Of having been engaged five years in the acquirement of professional knowledge. 3. Of having studied anatomy and physiology, by attendance on lectures and demonstrations, and by dissections, during two anatomical seasons. 4. Of having attended at least two courses of lectures on surgery, delivered in two distinct periods or seasons; each course to comprise not less than sixty lectures. 5. Of having attended lectures on the practice of physic, on chemistry, and on midwifery, during six months, comprising not less than sixty lectures respectively, and on botany and materia medica during three months. 6. Of having attended during twelve months the surgical practice of a recognised hospital in London, Dublin, Edinburgh, Glasgow, or Aberdeen; or for six months in any one of such hospitals, and twelve months in any recognised provincial hospital.

Regulations of the Council respecting the Professional Education of Candidates for the Diploma after the termination of the Session 1839-1840.

I. Candidates will be required to bring proof— 1. Of being not less than twenty-one years of age. 2. Of having been engaged in the acquirement of professional knowledge for not less than four years, three of which shall have been passed in a recognised school or schools of surgery; three months of vacation being allowed in each year, and, in the event of absence or absences from such school or schools during the said term of three years (exclusive of the vacations), the full term being completed subsequent year. 3. Of having studied anatomy and physiology, by attendance on lectures and demonstrations, and by dissections, during two anatomical seasons. 4. Of having attended at least two courses of lectures on surgery, delivered in two

distinct periods or winter sessons of six months, each course to comprise not less than seventy lectures. 5. Of having attended one course of lectures on the practice of physic, and one on chemistry, during six winter months, comprising not less than seventy lectures respectively; one course on materia medica with medical botany, during six months, and one on midwifery during six months, each comprising not less than sixty lectures, and at least twenty-five lectures on medical jurisprudence. Certificates of attendance on these lectures during the summer season will be received, provided they are equally divided over a period of four months. The lectures on medical jurisprudence may be delivered three days in the week. 6. Of having attended, during twenty-one months, the surgical practice of a recognised hospital in London, Dublin, Edinburgh, Glasgow, or Aberdeen; or for twelve months in any one of such hospitals, and twelve months in any recognised provincial hospital. 7. Of having attended the medical practice of a hospital or dispensary during six months.

II. Members and licentiates in surgery of any legally-constituted college of surgeons in the United Kingdom, and graduates in surgery of any University, requiring residence to obtain degrees, will be admitted for examination on producing their diploma, licence, or degree, together with proofs of being twenty-two years of age, and of having been occupied five years in the acquirement of Professional knowledge.

N.B. Certificates will not be recognised from any hospital unless the surgeons thereto, or a majority of them, be members of one of the legally-constituted colleges of surgeons in the United Kingdom, nor from any school of anatomy, physiology, or midwifery, unless the respective teachers be members of some legally-constituted college of physicians or surgeons in the United Kingdom; nor from any school of surgery, unless the respective teachers be members of some legally-constituted college of surgeons in the United Kingdom. Certificates will not be received on more than two branches of science from one and the same lecturer; but anatomy and physiology—demonstrations and dissections, materia medica and botany —will be respectively considered as one branch of science.

Regulations of the Council respecting the Professional Education of Candidates for the Diploma. August 15, 1843.

I. Candidates will be required, in addition to a certificate of being not less than twenty-one years of age, to bring proof—1. Of having been engaged in the acquirement of Professional knowledge for not less than four years; during which period they must have studied practical pharmacy for six months, and have attended one year on the practice of surgery at a recognised hospital or hospitals in the United Kingdom;—three months being allowed for a vacation in each year. (By a resolution of the Council, on the 7th of November, 1839, no provincial hospital will, in future, be recognised by the College which contains fewer than 100 patients, and no metropolitan hospital which contains fewer than 150 patients.) 2. Of having studied anatomy and physiology, by attendance on lectures and demonstrations, and by dissections, during three winter sessions, of not less than six months each. 3. Of having attended at least two courses of lectures on the principles and practice of surgery, delivered in two distinct periods or seasons; and one course on each of the following subjects, viz., the practice of physic, chemistry, and materia medica, and midwifery, with practical instruction.

Certificates will not be received unless the candidate have duly registered his tickets. The other regulations are virtually the same as before.

The Regulations of the Council respecting the professional education of candidates for the diploma of Member of the College, issued 16th of August, 1849, are as follows:—I. Candidates will be required to produce the following certificates, viz.:—1. Of being twenty-one years of age. 2. Of having been engaged during four years in the acquirement of professional knowledge. 3. Of having studied practical pharmacy during six months. 4. Of having attended at a recognised hospital or hospitals in the United Kingdom the practice of physic during one winter (a) and one summer (b) session. 5. Of having attended, during three winter and three summer sessions, the practice of surgery at a recognised hospital or hospitals in the United Kingdom. 6. Of having studied anatomy and physiology, by attendance on lectures and demonstrations, and by dissections during three winter sessions. 7. Of having attended, during two winter sessions, lectures on the principles and practice of surgery. 8. Of having attended, during one summer session, lectures on materia medica, and lectures on midwifery; practical midwifery to be attended at any time after the conclusion of the session. 9. And of having attended one course of lectures on the practice of physic and one course on chemistry. The course of study hereby prescribed is required to be observed by candidates who shall have pursued their studies in hospitals and schools in England. And those candidates who shall have studied in Ireland or Scotland will be admitted to examination upon producing certificates of having attended the required courses of lectures as delivered in the schools of Ireland and Scotland. 2. Members or licentiates of any legally constituted college of surgeons in the United Kingdom, and graduates in surgery of any university requiring residence to obtain degrees, will be admitted for examination on producing their diploma, licence, or degree, together with proof of being twenty-one years of age, and of having been occupied at least four years in the acquirement of professional knowledge. 3. Graduates in Medicine of any legally constituted College or University, requiring residence to obtain degrees, will be admitted for examination, on adducing, together with their diploma or degree, proof of having completed the anatomical and surgical education required by the foregoing regulations, either at the school and hospital of the University where they shall have graduated, or at one or more of the recognized schools and hospitals in the United Kingdom. 4. Candidates who shall have attended at recognized Colonial hospitals and schools, (c) the medical and surgical practice, and the several courses of lectures, with the demonstrations and dissections required by the foregoing regulations, will be admitted for examination upon producing certificates of such attendance, together with certificates of having attended in London, during one winter session, the surgical practice of a recognized hospital, and lectures on anatomy, physiology, &c., with demonstrations and dissections. 5. Certificates will not be recognized from any hospital unless the surgeons thereto be members of one of the legally-constituted Colleges of Surgeons in the United Kingdom; nor from any School of Anatomy and Physiology or Midwifery, unless the teachers in such school be members of some legally-constituted College of Physicians or Surgeons in the United Kingdom; nor from any School of Surgery, unless the teachers in such school be members of one of the legally-constituted Colleges of Surgeons in the United Kingdom. 6. Certificates will not be received on more than one branch of science from one and the same lecturer; but Anatomy and Physiology — Demonstrations and Dissections — will be respectively considered as one branch of science. 7. Certificates will not be received from candidates who have studied in London, unless they shall have registered their tickets at the College, as required by the Regulations, during the last ten days of January, March, and October in each year; nor from Candidates who have studied elsewhere, unless their names shall duly appear in the Registers transmitted during such studies from their respective schools.—By order of the Council.

Aug. 16, 1849. EDMUND BELFOUR, Sec.

N.B. In the certificates of attendance on Hospital Practice and on Lectures, it is required that the dates of commencement and termination be clearly expressed; and no interlineation, erasure, or alteration will be allowed. Blank forms of the required certificates may be obtained on application to the Secretary, to whom they must be delivered, properly filled up, ten days before the Candidate can be admitted to examination; and all such certificates are retained at the College.

These four forms of regulations are in force respecting candidates for the diploma, according to the period when they commenced their studies.

Fee for the diploma (including stamp), 22*l.*; for an articled student (allowed in the diploma fee), 10*l.* 10*s.*; for a certificate of having had the diploma, 5*l.* 5*s.*; for being enfranchised, 10*l.* 10*s.*; a certificate for a surgeon in the Royal Navy, or East India India Company's service (allowed in diploma fee), 5*l.* 5*s.*; for an assistant-surgeon, 2*l.* 2*s.*; for a candidate calling a special court, 5*l.* 5*s.*

Studentships in Anatomy.—Three studentships in human and comparative anatomy have been instituted by the College, to be held by each student for the term of three years, at a salary of one hundred pounds per annum. And with the view of promoting the objects of the College, in the institution of these studentships, the Commander-in-Chief of the Army, the Lords Commissioners of the Admiralty, and the Court of Directors of the East India Company, have placed at the disposal of the President and the Council an Assistant-Surgeoncy of each service, once in three years, for such of the said students as may be considered worthy of the honourable distinctions. 2. Candidates to be members of the College under twenty-six years of age. 3. The Council will determine annually whether one or more of such appointments shall take place during the current year, and will notify its resolution by public advertisement. 4. The appointment is made in the month of June, or as soon after as possible. 5. The students are subject to such duties and restrictions as the Council shall, from time to time, direct; and, in case of misconduct, are liable to dismissal. 6. Candidates are required to transmit to the Secretary, on or before the 1st of May, their applications for the appointment, together with certificates of general good character, and of fair acquirements in general learning, signed by two qualified members of the Medical Profession. 7. A meeting of the Museum Committee will be held as soon after the 1st of May as conveniently may be, at which the applications of the persons offering themselves will be examined, and, if approved, the applicants will be admitted as candidates. 8. The Museum Committee will determine the merits of the several candidates, and report to the Council which, in their opinion, possesses the highest merit. 9. The students are required to attend in the museum daily (Sundays excepted) from ten till four o'clock, and are under the immediate direction of the Museum Committee.

The *Museum* is opened to visiters on Monday, Tuesday, Wednesday, and Thursday, from twelve till four, except during the month of September; on Friday, to gentlemen for studying in it; and on Saturday, from ten till one, to gentlemen desirous of comparing specimens with those in the Museum. The *library* is open to members and students of the College, and visiters having tickets of admission, daily, (Sundays excepted,) from the 1st of October to the 1st of April, from ten till four; and from the 1st of April to the 1st of September, from ten till half-past five.

The Lectures at the College by the Professors

(a) The winter session comprises a period of six months, and, in England, commences on the 1st of October, and terminates on the 31st of March.

(b) The summer session comprises a period of three months, and, in England, commences on the 1st of May, and terminates on the 31st of July. No provincial hospital will be recognized by this College which contains less than 100 patients; and no metropolitan hospital which contains less than 150 patients.

(c) The recognition of Colonial hospitals and schools is governed by the same regulations, with respect to number of patients, to courses of lectures, and to Physicians, Surgeons, and Lecturers, as apply to the recognition of provincial hospitals and schools in England.

are delivered in the spring of the year, the Hunterian oration on the 14th of February.

APOTHECARIES' HALL.

Every candidate for a certificate or qualification to practise as an apothecary, will be required to produce testimonials—

1. Of having served an apprenticeship of not less than five years to an apothecary. No gentleman practising as an apothecary in England or Wales can give his apprentice a legal title to examination, unless he is himself legally qualified to practise as an apothecary, either by having been in practice prior to or on the 1st of August, 1815, or by having received a certificate of his qualification from the Court of Examiners. An apprenticeshi for not less than five years to surgeons practisir as apothecaries in Ireland and Scotland, gives t the apprentice a title to be admitted to examina tion.

2. Of having attained the full age of 21 years As evidence of age, a copy of the baptismal regist will be required in every case where it can possibl be procured.

3. Of good moral conduct. A testimonial o moral character from the gentleman to whom th candidate has been an apprentice, will always b more satisfactory than from any other person.

4. And of having pursued a course of medica study in conformity with the regulations of th Court.

Course of Study.

Every candidate whose attendance on Lecture shall commence on or after the 1st of Octobe 1849, must attend the following Lectures and M dical Practice during not less than three winter ar two summer sessions: each winter session to co sist of not less than six months, and to commenc not sooner than the 1st nor later than the 15th October; and each summer session to extend fron the 1st of May to the 31st of July:—

First Winter Session.—Chemistry; Anatom and Physiology; Anatomical Demonstrations.

First Summer Session.—Materia Medica an Therapeutics; Botany and Vegetable Physiology Midwifery, and Diseases of Women and Children.

Second Winter Session.—Anatomy and Physio logy; Anatomical Demonstrations; Dissections Principles and Practice of Medicine; Medica Practice. (a)

Second Summer Session.—Medical Practice; (a Midwifery, and Diseases of Women and Children Forensic Medicine; Practical Chemistry; (b) Mor bid Anatomy; Clinical Medicine.

Third Winter Session.—Dissections; Principl and Practice of Medicine; Medical Practice; (a Morbid Anatomy and Clinical Medicine.

Practical Midwifery, at any time after the conclusion of the first course of Midwifery Lectures.

The above course of study may be extended over a longer period than three winter and two summer sessions, provided the Lectures and Medical Practice are attended in the order prescribed.

Recognition of Lecturers and Schools.

No Member of the Court of Examiners will be recognised as a lecturer on any branch of medical science.

No lecturer will be recognised by the Court who is not connected with a recognised medical school; or who teaches on more than two branches of medical science; nor until he has produced very satisfactory testimonials of his attainments in the science he purposes to teach, and of his ability as a teacher thereof, from at least two persons of acknowledged talents and distinguished acquirements in the particular branch of science in question; and also given a public course of lectures on the subject he purposes to teach; but if, after such preliminary course, the lecturer shall be recognised, certificates of attendance on that course will be received.

Satisfactory assurance must also be given that the teacher is in possession of the means requisite for the full illustration of his lectures, viz., that he has, if lecturing—on Chemistry, a laboratory and competent apparatus; on materia medica, a museum sufficiently extensive; on botany, a Hortus Siccus, plates or drawings, and recent plants; on midwifery, a museum, and such appointment in a public Institution as may afford the means of practical instruction to the pupils.

Lectures on anatomy, and physiology, and anatomical demonstrations, must be in conformity with the regulations of the Royal College of Surgeons.

The lecturer on the Principles and Practice of Medicine, if he lectures in London, must be a Member of the Royal College of Physicians of London; and if in a provincial town, either a Member of the Royal College of Physicians of London, or a graduated Doctor of Medicine of a British University of four years' standing, unless prior to his graduation he had been for four years a licentiate of this Court.

The lecturer on Materia Medica and Therapeutics must be a Member of the Royal College of Physicians, or a graduated Doctor of Medicine of a British University of four years' standing, or he must have been a Licentiate of this Court for the same period.

The lecturer on Midwifery must be a Member of one of the legally constituted Colleges of Physicians or Surgeons in the United Kingdom of four years' standing, or he must have been a Licentiate of this Court for the same period.

The names of the lecturers recognised by the Court, may be known on application to the Secretary at the Hall of the Society.

The certificates of teachers recognised by the constituted medical authorities in Dublin, Edinburgh, Glasgow, and Aberdeen, as also those of the medical professors in foreign Universities, are received by the Court.

Much inconvenience having arisen from the presentation of schedules signed by lecturers unknown to the Court it is particularly requested that the Registrars of the medical schools will furnish a correct list of their recognised teachers to the Secretary of this Court, at the commencement of every winter session.

Hospitals and Dispensaries.

No Hospital will be recognised by the Court, unless, 1. It contain at least one hundred beds. 2. It be under the care of two or more Physicians, Members of the Royal College of Physicians of London or graduated Doctors of Medicine of a British University. 3. The Physicians give a regular course of Clinical Lectures and instructions in morbid anatomy. 4. The apothecary be legally qualified either by having been in practice prior to the 1st of August, 1815, or by having received a certificate of qualification from this Court. No Dispensary will be recognised by the Court, unless it be situated in some town where there is a recognised Medical School, and be under the care of at least two physicians and an apothecary legally qualified. [M]edical practice will be available, unless it [is a]ttended in conformity with the course of study [pr]escribed for pupils.

Registration of Testimonials.

All Testimonials must be given on a printed [sc]hedule and the *blanks* therein *must* be filled up by [th]e Lecturers themselves. Students will be supplied with schedules at the time of their first registration.

In London, at the Hall.

In Edinburgh, Messrs. M'Lachlan and Stewarts, booksellers.

In Dublin, at Messrs Hodges and Smith's, booksellers.

All Students, in London, are required *personally* to register the several classes for which they have taken tickets; and those only will be considered as complying with the regulations of the Court, whose names and classes in the register correspond with their schedules.

Tickets of admission to Lectures and Medical Practice must be registered in the months of October and May; but no ticket will be registered unless it be dated within *seven* days from the commencement of the course; and certificates of attendance must be registered in the months of April and August. Due notice of the days and hours of such registrations will be given from time to time.

The Court also require Students at the Provincial Medical Schools to register their names in their own hand-writing, with the registrar of each respective school, within the first twenty-one days of October and first fourteen days of May; and to register their certificates of having duly attended Lectures or Medical practice within fourteen days of the completion of such attendance.

The Registrars are requested to furnish the Court of Examiners with a copy of each registration *immediately* after its close, as those students only will be admitted to examination, whose registrations have been *duly* communicated to the Court.

Preliminary Latin Examination.

On the first Thursday in every month, those Students who have completed two Winter Sessions of their Medical studies, will be admitted to their Latin Examination, on leaving their schedules at the Beadle's Office, on or before the Monday preceding. Such Students will be required to attend on the Thursday at half-past three o'clock, and their schedules may be received again on the Saturday following; and those Students who fail to pass this Examination satisfactorily will not be re-admitted till they appear for their General Examination.

Examination.

Every person intending to offer himself for examination must give notice in writing to the Clerk of the Society on or before the Monday previously to the day of examination, and must at the same time deposit all the required testimonials at the office of the Beadle, where attendance is given every day, except Sunday, from ten until four o'clock.

The examination of the Candidate for a certificate of qualification to practise as an apothecary, will be as follows:—

In translating portions of the first four books of "Celsus de Medicinâ," and of the first twenty-three chapters of Gregory's "Conspectus Medicinæ Theoreticæ:

In Physicians' prescriptions, and the "Pharmacopœia Londinensis:"

In Chemistry:

In Materia Medica and Therapeutics:

In Botany:

In Anatomy and Physiology:

In the Principles and Practice of Medicine, including Midwifery and the Diseases of Children.

The examination of the Candidate for a certificate of qualification to act as assistant to an apothecary, in compounding and dispensing medicines, will be as follows:—

In translating Physician's prescriptions, and the "Pharmacopœia Londinensis:

In Pharmacy and Materia Medica.

By the 22nd section of the Act of Parliament, no rejected Candidate for a certificate to practise as an Apothecary, can be re-examined until the expiration of six months from his former examination; and no rejected candidate, as an assistant, until the expiration of three months.

The Court meet in the Hall every Thursday, where Candidates are required to attend at a quarter before four o'clock.

The Act directs the following sums to be paid for certificates:—

For London, and within ten miles thereof, ten guineas.

For all other parts of England and Wales, six guineas.

Persons having paid the latter sum become entitled to practise in London, and within ten miles thereof, by paying four guineas in addition.

For an Assistant's certificate, two guineas.

By order of the Court,

Henry Blatch, Secretary.

Apothecaries' Hall, June 1, 1849.

For information relative to these Regulations,

(a) Medical Practice must be attended during the full term of eighteen months; twelve months at a recognised Hospital, and six months either at a recognised Hospital or Dispensary.

(b) By Practical Chemistry is intended, a *specific* course of instruction in the Laboratory, with an opportunity of personal manipulation in the ordinary processes of Chemistry, and of acquiring a knowledge of the various re-agents for poisons.

Students are referred to the Beadle, at Apothecaries' Hall, every day, (Sunday excepted,) between the hours of ten and four o'clock.

It is expressly ordered by the Court of Examiners, that no gratuity be received by any officer or servant of the Court.

Information on all subjects connected with the "Act for better regulating the Practice of Apothecaries," may be obtained on application to Mr. R. B. Upton, Clerk of the Society, at the Hall, every day, (Sunday excepted,) between the hours of one and three o'clock.

HOSPITALS AND MEDICAL SCHOOLS.

ST. BARTHOLOMEW'S HOSPITAL AND MEDICAL COLLEGE.

The Hospital contains 580 beds; of which 400 are devoted to surgical cases and the diseases of the eye, and 180 to medical cases, and the diseases of women. The number of patients is upwards of 70,000 annually; of which the in-patients amount to nearly 6,000, the out-patients and casualties to 65,000.

Physicians—Dr. Hue, Dr. Roupell, Dr. Burrows. Surgeons—Mr. Lawrence, Mr. Stanley, Mr. Lloyd. Assistant-Physicians—Dr. F. J. Farre, Dr. Jeaffreson, Dr. Black. Assistant Surgeons—Mr. Skey, Mr. Wormald, Mr. Paget.

Fees of Attendance. — Medical Practice — Six months, 10 guineas; nine months, 12 guineas; eighteen months, 15 guineas; an unlimited period, 30 guineas. The clinical clerks to the Physicians are elected from the most diligent students. Surgical Practice—Six months, 15 guineas; twelve months, 20 guineas; three years, 25 guineas; an unlimited period, 30 guineas. Dresserships—Three months, 12*l.* 12s.; six months, 18*l.* 18s.; twelve months, 26*l.* 5s. The entrance to the Medical or Surgical Practice confers the right of attending the courses of clinical lectures by the Physicians or Surgeons.

Clinical lectures are delivered, during the summer session,—on Medicine, by Dr. Roupell, every Wednesday, at 12; and by Dr. Burrows, every Tuesday, at 12: on Surgery, by Mr. Lawrence, every Friday, at half-past 1; by Mr. Stanley and Mr. Lloyd, every Saturday, at half-past 12. The examinations after death are made in the Pathological Theatre, at 12 o'clock. Demonstrator of Morbid Anatomy, Dr. Kirkes, Registrar to the Hospital. Surgical operations, on Saturdays, at 1 o'clock The requisite opportunity of attending cases in Midwifery is provided for the students of the midwifery class.

The Museums of Anatomy, Materia Medica, and Botany, are open daily to the students of the respective classes. A Reading-room is open to all students of the school during the greater part of the day. Subscription, for three years, 10s. The Library contains upwards of 4,000 volumes of the standard works on Medical and other sciences, with the chief Medical journals, which are circulated among the subscribers. Subscription, for twelve months, 1*l.* 1s.; for three years, 1*l.* 10s.; for an unlimited period, 2*l.* 10s.

Collegiate Establishment.—Under the direction of the Treasurer and a Committee of the Governors of the Hospital, houses within the Hospital walls have been fitted up as a College, for the residence of forty students. The establishment is under the superintendence of the resident warden, Mr. Paget; from whom the rules may be obtained.

Scholarships and Prizes.—Examinations are held in the several classes at the end of each winter session, and scholarships, prizes, and honorary distinctions are awarded in May. A scholarship, of the value of 45*l.* a year, and tenable for three years, will be awarded in May, 1850. The subjects of examination will be Anatomy and Physiology. The Bentley Scholarship, of 50*l.* for one year, will be awarded at the same time. The subjects of examination will be Medicine and Surgery. The Wix Prize, founded by the Rev. S. Wix, Vicar and Hospitaller, will, in 1850, be given for the best Essay on the Connexion between Ancient and Modern Literature and the Study of the Medical Sciences. The President's Prize will, in 1850, be given for the best Report of Medical Cases observed in the Hospital during the previous year. The Bentley Prize, founded by James Bentley, Esq., Treasurer of the Hospital, will, in 1850, be given for the best Report of Surgical Cases observed in the Hospital during the previous year. The Collegiate Prize will, also, be given by the Treasurer to the Resident Student of the College who obtains the highest honours in the Class Examinations. Mr. Lloyd will give a Prize for the best Report of Cases of Diseases of the Joints occurring in the Wards under his charge. Prizes of books, or instruments, and honorary certificates, are awarded to the students who give proof of proficiency in the several subjects of study.

Further information, in regard to every department of the College, may be obtained from any of the medical or surgical officers, or lecturers; or on application at the Anatomical Museum, or the Library.

ST. THOMAS'S HOSPITAL.—MEDICAL AND SURGICAL SCHOOL.

Hospital Staff.—Dr. Roots, Consulting Physician; Dr. Barker, Dr. Leeson, Dr. Bennett, Physicians; Mr. Green, Mr. South, Mr. Macmurdo, Surgeons; Dr. Goolden, Dr. Cohen, Assistant Physicians; Mr. Solly, Mr. Le Gros Clark, Mr. Dixon, Assistant Surgeons; Mr. Simon, Lecturer on General and Clinical Pathology; Mr. B. Marsack, Mr. P. H. Bird, House Surgeon. Ophthalmic Department.—Mr. Mackmurdo, Surgeon; Mr. Dixon, Assistant Surgeon. Dr. Waller, Physician Accoucheur; Mr. C. O'Callaghan, Resident Accoucheur.

The out-patients are seen at nine o'clock.—The wards are visited daily, commencing at twelve.

Gentlemen proposing to become Students of St. Thomas's Hospital are expected to produce satisfactory testimonials of moral character and general education; and, with a view of encouraging those acquirements which tend to raise the character of the Profession, the Governors have decided on instituting a voluntary examination in classics, and mathematics. The admission fee to Hospital Practice and all the lectures is 40*l.* for the first year, a similar sum for the second, and 10*l.* for each succeeding year. Special entries to any course of lectures, or to Hospital Practice, may be made as heretofore. The most meritorious of the students will be selected to hold the following appointments in the hospital, without the payment of any additional fee; viz., those of House Surgeon, Physician's Clinical Clerk, Surgeon's Dresser, and Resident Accoucheur. Examinations will be held at the end of the several terms, winter, spring, and summer.

Scholarships and Prizes.—A scholarship of 20*l.* for the student who shall pass the best voluntary classical and mathematical examination, at the commencement of his hospital attendance. Two scholarships for first year's men, each of the value of 20*l.* a year, and tenable for three years, will be awarded annually. The Resident Accoucheur will be provided with rooms and commons in the hospital, free of expense. He will be selected, upon examination, from those Students who, being otherwise qualified, have attended the greatest number of cases. The dressers will be selected according to merit at the periodical examinations. They will be provided with rooms and commons in the hospital, free of expense, during their weeks of attendance. The House Surgeons, two in number, will be selected annually. They will be provided with rooms and commons in the hospital, free of expense. These appointments will be awarded to gentlemen who have most distinguished themselves as Dressers. They must be members of the Royal College of Surgeons, and either licentiates of the Society of Apothecaries, or graduates in Medicine. Prizes and certificates of honour will also be awarded to those who distinguish themselves at the periodical examinations in each subject. Two prizes to Clinical Clerks: The first prize to the value of five guineas, the second three guineas. The President's prizes: The first to the value of ten guineas, to be awarded for attention and good conduct, to the Dresser who shall have reported most accurately the greatest number of surgical cases. The second, to the value of five guineas, to be awarded to a second year's student for the best report of medical cases. Dr. Roots's prize, to the value of ten guineas, will be awarded to the Physician's Clinical Clerk, who shall produce the best report of not fewer than twelve medical cases, which have occurred in the hospital during the preceding twelve months, each case being accompanied with notes illustrative of its pathology, diagnosis, and treatment. One of the Governor's—a prize to the value of five guineas, will be awarded to the Student, who shall write the best report on the ophthalmic cases which shall have been admitted into the hospital. The Treasurer's Annual Prizes.—The first, a gold medal for general proficiency and good conduct, for Students at the completion of their studies; the second to the value of five guineas, for the best Essay read before the Physical Society. The Treasurer's Prize.—One hundred pounds will be awarded in 1851, to the author of the best Essay, including original researches on organic chemistry, in its relation to pathology and practical medicine. The special subject of the Essay is, "On the Chemical and Physiological Action of Mercurial Preparations."

Mr. Whitfield, Resident Medical Officer, is authorised to enter Students, and will give detailed conditions of the various prizes, with any other particulars which may be required.

GUY'S HOSPITAL.

Consulting Physician—Richard Bright, M.D., F.R.S. Physicians—Thomas Addison, M.D.; B. G. Babington, M.D., F.R.S.; G. H. Barlow, M.D. Assistant-Physicians—H. M. Hughes, M.D.; G. Owen Rees, M.D., F.R.S; Golding Bird, M.D., F.R.S. Surgeons—Bransby B. Cooper, Esq., F.R.S.; Edward Cock, Esq.; John Hilton, Esq., F.R.S. Assistant-Surgeons—John Birkett, Esq.; Alfred Poland, Esq; Obstetric Physicians—J. C. W. Lever, M.D.; Henry Oldham, M.D. Surgeon of the Eye Infirmary—John F. France, Esq. Apothecary—James Stocker, Esq.

Gentlemen, who desire to become students, must give satisfactory testimony as to their education and conduct. They are required to pay 40*l.* for the first year, 40*l.* for the second year, and 10*l.* for every succeeding year of attendance. The ticket for the year admits to the lectures, practice, and all the privileges of a student; and for that year only. Dressers, clinical clerks, assistants, and resident obstetric clerks are selected from those students who have attended a second year. Tickets will be withdrawn in the event of neglect or misconduct. Certificates will be given for lectures and practice which have been duly attended. The Christmas recess will commence December 22, and the lectures will be resumed January 3. The winter session will terminate March 31, and the summer course will commence May 1.

The Library, Museum, and Model rooms, are open to the pupils. Mr. Stocker, Apothecary to Guy's Hospital, is authorised to enter the names of students.

UNIVERSITY COLLEGE, LONDON.

Frequent examinations are held in every class. Medals and certificates of honour are given in every class at the end of each term; but those pupils only who have regularly attended the examinations will be admitted to contend for them. At the end of every session the "Longridge" exhibition of 40*l.* is awarded as a prize for general proficiency.

The payments are made by students nominated by proprietors: 5s. additional for every pound, until this extra payment amounts to 4*l.* 10s, are paid by those not nominated. A college fee of 10s. for one class, and 1*l.* for two or more classes, is paid by each student every session; where, however, the course is of short duration, this fee is diminished. The matriculation fee of 2*l.* relieves the student, during the whole course of his study, from the College fee. All fees are paid at the office of the College, where the student receives his tickets, which he afterwards takes to be signed by the Professor. The office is open from 9 o'clock till 4, except on Saturdays, when it closes at 2.

Several of the Professors receive students to reside with them; and in the office of the College there is kept a register of parties unconnected with the College who receive boarders in their families;

among these are several medical gentlemen. The Register will afford information as to terms and other particulars. At University hall, an Institution in the neighbourhood of the College, collegiate residence under the superintendence of a Principal is provided for a limited number of students.

UNIVERSITY COLLEGE HOSPITAL.

Physicians.—Dr. Walshe, Dr. Parkes, Dr. ——; Dr. Murphy, Obstetric Physician; Dr. Garrod, Dr. ——, Assistant-Physicians.

Surgeons.—Mr. Arnott, Mr. Quain, Mr. Mortoft; Mr. Erichson, Mr. Marshall, Assistant Surgeons; Mr. Durance George, Dental Surgeon.

To students who have already entered, in the medical faculty of the College, to three classes, of which the courses are of six months' duration—(two classes, in which the courses are of three months' duration, being considered equivalent to one of six months)—also to pupils who produce certificates of having attended a course of lectures of a recognised school of medicine, and during one year the practice of a recognised hospital: For perpetual admission to the medical and surgical practice, 26*l.* 5s. For one year to the Physicians' and Surgeons' practice, 21*l.*; Physicians' or Surgeons' practice separately, 15*l.* 15s.. For six months to the Physicians' and Surgeons' practice, 15*l.* 15s.; Physicians' or Surgeons' practice separately 10*l.* 10s.

To pupils other than as above specified:—For perpetual admission to the medical and surgical practice, 36*l.* 15s. For one year to the Physicians' and Surgeons' practice, 30*l.*; Physicians' or Surgeon's practice separately, 22*l.* For six months to the Physicians' and Surgeons' practice, 22*l.*; Physicians' or Surgeons' practice separately, 15*l.* The above fees to be paid at the office of the College. These fees are devoted to the maintenance of the Hospital, the Physicians and Surgeons having relinquished their proportion of them for its benefit. Every pupil pays, in addition to the fees, 10s. Apothecary's, and 5s. office fee.

Physicians's Assistants, House Surgeons, Midwifery Assistants, Physicians' Clerks, and Surgeons' Dressers are selected from pupils, being students of the College and of unexceptionable moral character, without additional payments. In case of the qualifications of the candidates for the respective offices being equal, preference will be given to those who have obtained the highest honours in the medical classes of the College. The Physicians' Assistants and House Surgeons reside in the Hospital, paying for their board. The Physicians' and Surgeons' visits are made daily at 1 and 2 o'clock. Each of the three Physicians visits his patients three times a week.

Obstetric Department.—Dr. Murphy attends three times a week to see patients affected with uterine diseases, and children; and on alternate days to receive applications from women who wish to be attended in their confinement.

Out-patients' Department.—Out-patients are seen daily by the Assistant Physicians, Surgeons, and Assistant-Surgeons.

KING'S COLLEGE.—Session 1849 50.

Medical Department—The academical year in this department is divided into two sessions; the winter session, which will begin on the 1st of October, and terminate on the 31st of March; and the summer session, which will begin on the 1st of May, and end on the 31st of July. Students are of two kinds, matriculated and occasional. Matriculated students are those who receive their entire medical education at King's College. They wear the College cap and gown, and enjoy certain privileges enumerated in the Calendar. Occasional students comprehend those who attend only the lectures of particular Professors.

KING'S COLLEGE HOSPITAL.

The Hospital is situate in the immediate neighbourhood of the College, and accommodates 120 in-patients.

Consulting Physicians—Thomas Watson, M.D.; Robert Ferguson, M.D. Physicians—George Budd, M.D. F.R.S.; R. B. Todd, M.D. F.R.S. Physician for Diseases of Women and Children, and Physician Accoucheur—Arthur Farre, M.D., F.R.S. Physician to Out-patients.—W. A. Guy, M.B. Assistant Physician—George Johnson, M.D. Surgeons—W. Fergusson, F.R.S.; Richard Partridge, F.R.S. Assistant-Surgeons—William Bowman, F.R.S.; Henry Lee, F.R.C.S. Surgeon-Dentist —S. Cartwright, jun.

Dr. Arthur Farre attends at half-past eleven on Tuesday, Thursday, and Saturday.

Clinical lectures are delivered, after the visit, on alternate Tuesdays, by Dr. Todd; Fridays, by Dr. Budd; Mondays, by Mr. Partridge; Thursdays, by Mr. Fergusson.

The Physician's Assistant and Clinical Clerks, the House Surgeon and Dressers, are selected by examination from among those matriculated students of the College who are pupils of the Hospital. —No fee is paid for any of these appointments.

The expense of the course of study required by the regulations of the College of Surgeons and the Society of Apothecaries is 96*l.* 12s. This payment may be made either in one sum upon matriculation, or in two equal sums; the one at the commencement of the winter session, October 1st, and the other after the Christmas vacation, not later than the 21st January. The following fees must be paid at the time of matriculation:—Matriculation fee, 1*l.* 1s.; library fee, 1*l.* 1s.; subscription to the scholarship fund, 1*l.* 1s.; cap and gown, 1*l.* 10s.; calendar, 2s.: total, 4*l.* 15s. The fees for admission to the laboratory class of analytical chemistry are, for one month, 4*l.* 4s.; for three months, 10*l.* 10s.; for six months, 18*l.* 18s.; for nine months, 26*l.* 5s. Fee for the Medical Tutor, to resident students, 2*l.* 2s. for each academical year; to non-resident students, 3*l.* 3s. All resident students are required to attend the Medical Tutor during their first two years.

Hospital Fees.—Perpetual admission to the Medical and Surgical Practice:—For Matriculated Students of King's College, 31*l.* 10s. For Pupils who are not Matriculated Students, 36*l.* 15s. Medical Practice:—Three months, 6*l.* 6s.; six months, 10*l.* 10s.; twelve months or eighteen months, 15*l.* 15s.; perpetual 21*l.* Surgical Practice:—Three months, 10*l.* 10s.; six months, 15*l.* 15s.; twelve months or twenty-one months, 21*l.*; Perpetual, 26*l.* 5s. Registration-fee, to be paid to the Secretary at King's College Hospital, 10s. 6d.

Endowments and Prizes in favour of Medical Students.—1. Scholarships, given annually.—One of 40*l.* for students of the third and fourth year, tenable for three years; one of 30*l.*, for students of the second year, tenable for two years; and three of 20*l.*, for students of the first year, tenable for two years. 2. Leathes Prizes.—The interest of 300*l.* bequeathed by the late Mr. Leathes, is applied in the purchase of a Bible and Prayer-book, as yearly prizes, to two medical students, who shall be found most worthy of the same, for their proficiency in religious knowledge, and their general conduct. 3. Warneford Prizes.—The interest of 1000*l.* given by the Rev. Dr. Warneford, is expended in the purchase of two medals, and of books to be given annually to two medical students who shall most distinguish themselves at an examination consisting of questions in—1. The Holy Scriptures; 2. Butler's Analogy; 3. Two branches of medical science taught in the College, to be selected by the candidates. The first prize is of the value of 25*l.*, and the second of 15*l.* Matriculated students only can become candidates for these prizes and scholarships. The examination for the Warneford and Leathes prizes takes place in October, and for the scholarships after the winter session. Candidates for the Warneford and Leathes prizes must bring certificates of regular attendance at the College chapel; and candidates for the Warneford prizes must also bring certificates of attendance at the lectures of the Principal and Chaplain. 4. Daniell Scholarship.—This scholarship has been founded in honour of the late Professor Daniell, and is open to every student of the College. It is of the annual of 20*l.*, tenable for two years; and is given every second year for the best series of researches in chemistry made in the laboratory of the College since the last award. 5. Prizes and certificates of honour are awarded in the different classes, according to fixed regulations. 6. Clinical prizes and certificates of honour are likewise given for proficiency in subjects taught at the hospital. Associates of King's College.—This distinction is conferred at the recommendation of the Professors, on such Students as, having completed with distinction four years of study, are approved by the Principal. Degrees.—Students of this College are admitted to degrees in Arts and Medicine, and for the honours, exhibitions, and scholarships conferred by the Senate of the University of London. By a regulation of the University of Edinburgh, three out of the four years of study required by that University for its degree of M.D., may be passed at King's College. Residence of Students.—Students may reside in the College; and some of the Professors receive pupils into their houses. The parents or guardians of students coming to King's College are earnestly requested to communicate with the Dean of the medical department before placing them in lodgings. Dining-hall.—There is a dining-hall in the College for the accommodation of the resident students, and for such other students as may desire to avail themselves of it. Further particulars may be obtained from the King's College Calendar; or by application to Professor Guy, the Dean of the medical department, or to J. W. Cunningham, Esq., Secretary of King's College, London. The next winter session will commence on Monday, the 1st of October next, with an introductory lecture by Professor Arthur Farre, at two o'clock precisely.

THE QUEEN'S COLLEGE, BIRMINGHAM.

Department of Medicine and Surgery.

The system of study pursued at this College constitutes a complete course of collegiate, medical, and surgical education. The lectures qualify for examination for the diplomas of the Royal College of Surgeons and the Society of Apothecaries, without any residence elsewhere. Students who have passed through the junior department of this College, and have there in due course matriculated at the University of London, may present themselves for their B A. or first M.B. examination at the end of their first year in the medical department. At the end of the second year, matriculated students who deferred their examination in the University of London, have again the opportunity of presenting themselves. At the end of the third year, students are eligible for M.A. and M.B. degrees in the University of London, for the diploma of the Royal College of Surgeons of England, and the license of the Society of Apothecaries. The academical year is divided into two sessions: the winter session, which commences on the 1st of October, and terminates in April; and the summer session, which begins on the 1st of May, and ends July 31st. Connected with the College are Museums of Human, Comparative, and Pathological Anatomy, containing upwards of 2,000 preparations, to which the student will be admitted daily; and, under certain regulations and restrictions, he will also have access to an extensive Museum, illustrative of zoology, geology, and the other departments of natural history. The Library contains upwards of 2,000 volumes; and the quarterly, monthly, and weekly periodicals of medicine and surgery and general science lie upon the table. The college expenses, including commons, chamber rent, and servants' wages, &c. &c., will not exceed 48*l.* for the two sessions. The students breakfast in hall at seven, a.m., have refreshment at twelve, dine at five, p.m., have coffee at eight, p.m. The payments to be made by three instalments, viz., 18*l.* on the 1st of October, 18*l.* on the 1st of January, and 12*l.* on the 1st of May. Every student will be expected to provide himself with chamber linen, a large and small silver fork, and a table spoon and tea spoon.

College Regulations.—1. Every student shall annually subscribe his name in the obligation book, and shall sign a declaration that be will regularly and diligently pursue his studies. 2. Students to attend prayers daily, and on Sunday Divine service in the Chapel, and also the Warden's theological lectures and

examinations. 3. Students to have furnished room with commons in college. 4. Students to wear the academical dress whenever they appear in hall, or at lectures, and in the College Chapel. 5. The names of students who come into college after ten o'clock p.m., to be entered in a book, to be kept by the porter, with the hour at which they come in. 6. No student to be absent from college any night during his residence without the express permission of the senior tutor. 7. In case of infringement of the rules and regulations of the College, the Senior Tutor shall have power to enforce the same, 1st, by restraint of hours, —2nd, by literary exercises, called impositions,—3rd, by suspension. In any case in which suspension is necessary, the Senior Tutor shall inform the several Professors thereof, in order that the attendance of such student at lectures be discontinued, and their certificates disallowed. In any case in which the Senior Tutor shall consider rustication necessary, he shall confer with the Warden, and the Warden and Senior Tutor together may rusticate for any period not exceeding two months. Whenever the Senior Tutor considers dismissal or expulsion necessary, he is to report the same in writing to the Council, together with a detailed statement of the circumstances. The Council, after deliberation thereupon, shall communicate its decision to the Senior Tutor, and such decision is final.

A book will be kept by each Professor specifying the dates of attendance of each student. Testimonials as to such attendance and as to professional acquirements will be given by the Professors in such printed forms only as have been agreed upon by them. A *vivâ voce* examination will be held in each class every week or fortnight, at the discretion of the Professor, and on the last day of each course there will be a general written examination in every class, at which all the students must attend. The Professors' medals and certificates of honour will be awarded to those students who, in such written examinations, shall display the greatest proficiency. During the last week of the winter and summer sessions, the schedules of the Royal College of Surgeons and Society of Apothecaries on Lectures and hospital practice are to be left with the Registrar; the schedules, duly signed by the respective Professors, will afterwards be delivered to students, by the Curator, on the last day of each term. Certificates will not be granted to those students who neglect to comply with this regulation.

Such members of the College as hold a diploma in medicine or surgery, or who are graduates in medicine, law, or arts, or such members of the late Birmingham Royal School of Medicine and Surgery as the Council may determine, are eligible to be "fellows." The fellows have power to vote at all special and general meetings, have free admission to the medical and general library, to the museums, and to the lectures of the Professors; and likewise are privileged to dine in the College-hall, on the payment of a specified sum, to be fixed by the Council. Four resident scholarships have been founded by the Rev. Dr. Warneford, of 10*l*. each, to be held for two years; to be conferred upon the students who have resided in the College at least twelve months, who have been distinguished for their diligence and good conduct, who have been regular in their attendance on Divine service, and who have availed themselves especially of the religious instruction of the Warden. The interest of 1,000*l*. to be applied for the institution of two prizes, either in equal or unequal amounts, as may seem to the Trustees most likely to advance the great ends in view, which are, to combine religious with scientific studies and pursuits, to make medical and surgical students good Christians, as well as able Practitioners in medicine and surgery. The compositions written for these prizes to be of a religious as well as scientific nature; the subject to be taken out of any branch of anatomical, physiological, or pathological science, and to be handled in a practical or professional manner, and according to those evidences of facts and phenomena which anatomy, physiology, and pathology, so abundantly supply; but always and especially with a view to exemplify and set forth, by instance and example, the wisdom, power, and goodness of God, as revealed and declared in Holy Writ. Two gold medals are offered by the Governors of the College for regularity of attendance at lectures and examinations, and good conduct during two years; to be certified by the senior tutor and professors. Silver medals are annually given by each professor, on a public examination, of proficiency in the respective departments of medical science, at the conclusion of the summer session. Certificate of Honour.—Students who may, after examination, be placed by the Professor next to the medallist, will receive a certificate of honour, signed by the Principal, Vice-Principal, and Dean of the Faculty. University Scholarships &c.—Students of the college are admitted to examination for the scholarships, exhibitions, gold medals, and books, offered by the Senate of the University of London. Students are also eligible to contend for the commission in the army, offered to the Senate of the University by the Army Medical Department once in every two years, for one of its most distinguished bachelors of medicine. Studentships, &c., of the Royal College of Surgeons.—Students are eligible to offer themselves for the studentships of the Royal College of Surgeons of England, of the value of 100*l*. per annum for three years, (three of which have been established), for the best proficients in human and comparative anatomy. The General commanding the Army in Chief, the Lords Commissioners of the Admiralty, and the Court of Directors, have (at the instance of the Director-General of the Medical Department of the Army, the Physician General of the Royal Navy, and the Chairman of the Honourable East India Company) placed the appointment of an assistant surgeon at the disposal of the President and Council of the Royal College of Surgeons once in three years, for such students as may be considered worthy of these honourable distinctions. These appointments are also open to the students of the College. Non-resident students are admissible, and may reside with their parents or guardians, or with a relation or friend selected by their parents or guardians, and approved by the Council. The Senior Tutor and Dean of the Faculty are authorized to inquire into the habits and general conduct of such out-students at their respective residences, and to report to the Council thereupon, at the end of every term. Out-students, if members of the Church of England, will be required to attend Divine service in the College Chapel every Sunday, unless the parent or guardian of the student requests the attendance of such student at his own place of worship. If the student be attached to any other communion, he will be expected to attend at the place of worship belonging thereto every Sunday. Non-resident students will be allowed to dine in the College hall, either regularly or occasionally, on giving such notice, and paying such sum, as shall be fixed by the Council.

QUEEN'S HOSPITAL, BATH-ROW.

Fees for Admission to the Hospital Practice, and to the Clinical Lectures.—Students may compound for three years, on the payment of 21*l*.; one year's attendance, 10*l*. 10*s*. The respective offices of House Surgeons, Physicians' Clerks, and Surgeons' Dressers, shall be filled up by the medical officers from the students of the Queen's Hospital, after public examination, and the production of testimonials of good conduct. Clinical lectures will be delivered weekly, by the Professors, in the theatre. A gold medal is offered by Professor Dr. Davies for the best reported medical cases occurring in his practice at the Queen's Hospital. A gold medal is offered by Professor Cox, for the best reported surgical cases occurring in his practice at the Queen's Hospital. All fees are paid to the Deputy Treasurer, Professor Davies, M.D., 25, Newhall-street, from 9 o'clock until 10 in the morning, where the student may obtain his ticket. The registry of tickets to the lectures and hospital practice is open from October 1st to October 21st, and from May 1st to May 14th, every year. Applications to be made and the tickets brought to the Registrar, W. Sands Cox, Esq., F.R.S., at the College, at the hour specified. It is the earnest request of the Council, that parents or guardians of medical students coming to Queen's College, should make early application to W. Sands Cox, Esq., 24, Temple-row, as only a limited number of rooms have been provided.

LONDON HOSPITAL MEDICAL AND SURGICAL SCHOOL, MILE END. 1849-50.

General fee for attendance on the medical and surgical practice and all the lectures, qualifying for the examinations at the London University, Royal College of Surgeons, and Apothecaries' Hall, 84 guineas, payable in two instalments of 42 guineas each, at the commencement of the two first sessions of attendance. General fee to the lectures alone 50*l*. Students can make special entries for lectures or practice as heretofore.

Hospital Practice.—The London Hospital contains 320 beds, of which 100 are allotted to Medical, and 220 to surgical cases. Physicians—Dr. Cobb, Dr. Frampton, Dr. Little. Assistant-Physicians—Dr. Pereira, Dr. Fraser, Dr. Davies. Surgeons—Mr. Luke, Mr. Adams, Mr. Curling. Assistant-Surgeons—Mr. Critchett, Mr. N. Ward. One of the Physicians and one of the Surgeons attend daily; the latter at one o'clock; and one of the Assistant-Physicians and one of the Assistant-Surgeons daily at twelve. Casualties are received at all hours in the accident-room by the house-surgeons and dressers. Surgical operations, except in cases of emergency, are performed on Thursdays at one o'clock. Consulting Physician in Obstetric Cases, Dr. Ramsbotham, who attends on Mondays at one p.m.

Fees of Attendance on the Hospital Practice.—On the Medical Practice—For six months, 6 guineas; for period required by Apothecaries' Hall, 11 guineas. On the Surgical Practice and Dressing—For twelve months, including six months' dressership, 12 guineas; for eighteen months, including twelve months's ditto, 18 guineas; for three years, including twelve months' ditto, 25 guineas; for twelve months' additional dressership, during the above three years, 5 guineas; for twelve months' dressership, after expiration of the above three years, 8 guineas. The pupils enter and dress under all the Surgeons. Two in rotation remain in the hospital day and night for a week, and are provided with commons. The privilege of dressing for twelve months is given annually to three pupils of the school, each pupil being previously required to dress the out-patients for one year. Two House-Surgeons are elected every six months, without any additional fee. They reside in the hospital, and are provided with commons.

Clinical lectures will be given by the Physicians and Surgeons. The *post-mortem* examinations take place, as opportunities occur, at two p.m. Microscopical demonstrations of Morbid Anatomy will be given by Dr. Parker. The Anatomical Museum is open daily to the students from eleven a.m. to two p.m. The Reading room is open daily from ten a.m. to four p.m. Gentlemen, who have entered to the medical or surgical practice, or to two or more courses of lectures, will be admitted, without any fee, to the Reading-room; and to the privileges of the Library, on depositing 1*l*., to be returned at the termination of the period of study at the hospital. A Cabinet of Materia Medica is open to the students. Medals and certificates of merit will be offered for competition in all the classes.

Hospital Prizes.—Two gold medals will be annually awarded by the Governors to such students attending the medical and surgical practice, as shall have most distinguished themselves in the performance of their duties at the hospital.

Further information may be obtained from Mr. Adams or Mr. Curling, or on application to Dr. Letheby, at the Anatomical Museum.

MIDDLESEX HOSPITAL SCHOOL OF MEDICINE. SESSION 1849-50.

Physicians—Francis Hawkins, M.D.; Mervyn A. N. Crawford, M.D.; Seth Thompson, M.D. Physician-Accoucheur—Charles West, M.D. Assistant-Physician—Robert Gordon Latham, M.D., F.R.S. Surgeons—Mr. Alexander Shaw, Mr. Campbell de Morgan, Mr. Charles H. Moore. Assistant-Surgeon—Mr. Mitchell Henry. Surgeon-Dentist—Mr. Tomes. Apothecary—Mr. Corfe.

The Hospital has recently been much enlarged, and important alterations and improvements have been introduced in its internal arrangements. It now receives 285 in patients, and contains wards specially appropriated to the admission of cases of syphilis and of cancer, in the male and female, and of uterine disease. Clinical Clerks and Dressers are selected by the Physicians and Surgeons of the Hospital from the most deserving pupils, without additional fee. Pupils are required to dress in the out-patient room and surgery before becoming eligible as dressers to the in-door patients. A Senior and Junior House-Surgeon are elected half yearly from the Dressers, and are provided with board and residence in the Hospital, free of expense. The in-patients are visited daily, at one o'clock punctually. Clinical Lectures will be given during the Winter and Summer Sessions. Clinical Prizes.—With a view to encourage the habit of investigating and recording at the bedside the phenomena of disease, the Physicians and Surgeons have instituted two prizes, of the value of 10 guineas each, which will be awarded, at the Annual Distribution, to the Students who shall present the best reports of cases that have occurred in the Hospital during the preceding Winter Session. Practical instruction in minor surgery, bandaging, &c., will be given by the Assistant-Surgeon. The hours of lecture, &c., have been so arranged as to allow as large an amount of time as possible for attendance in the wards of the Hospital, and at *post-mortem* examinations, and for dissection. The average annual number of out patients treated during the past five years is 9,316 The medical and surgical out-patients are attended on three days in the week by the Assistant-Physician and Assistant-Surgeon respectively, at 8 a.m. and every opportunity is taken to render this department available to the pupils for the prompt and ready investigation of disease. Midwifery and the Diseases of Women and Children.—Upwards of 500 cases of labour were attended under the direction of the Physician-Accoucheur, during the last year, and the students are at all times furnished with an ample supply of cases under his superintendence. Out-patients with uterine and infantile diseases are seen by the Physician Accoucheur on Mondays and Thursdays at twelve o'clock. Ophthalmic Department.—Patients with diseases of the eye are attended by Mr. De Morgan, on Mondays, Wednesdays, and Fridays, at twelve o'clock. Dental Surgery.—Pupils receive instruction in the operations and diseases of the teeth on Tuesdays, Thursdays, and Saturdays, at nine o'clock, from the Surgeon-Dentist. Morbid Anatomy and Pathology.—Post mortem examinations are performed by the Assistant Surgeon at two o'clock.

Medical Practice.—For three months, 6*l*. 6s; six months, 10*l*. 10s.; eighteen months, 15*l*. 15s.; an unlimited time, 21*l*. Surgical Practice.—For three months, 9*l*. 9s.; six months, 12*l*. 12s.; three years, 18*l*. 18s.; an unlimited time, 21*l*. Fee to the Apothecary, 1*l*. 1s. Fee to the Secretary, 5s. Students who are desirous of entering to the Medical and Surgical Practice of the Hospital, apart from the Lectures, for the periods required by the College of Surgeons and Apothecaries' Company, (viz., eighteen months of medical and three years of surgical practice,) may do so by making one payment of 30*l*. This includes the fees of the Apothecary and Secretary.

Instruction in Practical Pharmacy, with opportunities of Dispensing, is given by the Apothecary. Fee, for six months, 8 guineas; for twelve months, 12 guineas.—Instruction in Pharmacy, in the Drug room, without Dispensing. For three months, 6 guineas.

The Museum is open to students daily, and bones and models are supplied to them in it for study during the intervals of lecture. Students have frequent opportunities of making microscopical examinations of natural and morbid structures. Admission to the Library and Reading-room is included in the fees paid by general students. Occasional students, who desire to make use of the Library, may do so on payment of half a guinea. The Library has been considerably enlarged; it now contains an extensive collection of standard medical works, with the various medical periodicals. For the convenience of students, the authorities of the Hospital have made arrangements, by which they may dine with the resident officers, at the Board-room table. Parents and guardians who propose sending pupils to the school, may communicate with Mr. De Morgan, Treasurer to the school, at the Hospital, daily, from twelve to two o'clock; or information may be obtained on application to any of the Lecturers, or to Mr. Curfe, the Apothecary, at the Hospital.

ST. GEORGE'S HOSPITAL MEDICAL SCHOOL. SESSION 1849—50.

Hospital Practice.—Physicians—Dr. Wilson, Dr. Nairne, Dr. Page, and Dr. Bence Jones, F.R.S. Assistant Physicians—Dr. Pitman and Dr. Fuller. Surgeons—Mr. Keate, Mr. Hawkins, Mr. Cutler, and Mr. Tatum. Assistant Surgeons — Mr. H. Charles Johnson and Mr. Prescott Hewett.

Gentlemen are admitted to the Practice of the Physicians on the following terms:—Six months, 8 guineas; one year, or the period required by the Society of Apothecaries, 16 guineas; perpetual pupils, 24 guineas; fee to the apothecary, 1 guinea. Gentlemen are admitted to the Practice of the Surgeons on the following terms:—Six months, 15 guineas; one year, or the period required by the College of Surgeons, 20 guineas; perpetual pupils, 50 guineas.

Attendance of the Physicians and Surgeons daily at one o'clock. Surgical operations on Thursday. Clinical lectures are given by the Physicians and Surgeons of the Hospital during the Winter and Summer Sessions. Patients with diseases of the eye are treated by Mr. Tatum on Mondays and Fridays, at one o'clock. Gentlemen may be instructed in Pharmacy, in the Laboratory and Dispensary of the Hospital on the following terms:—Six months, 12 guineas; one year, 15 guineas. The pupils attending the Medical practice may become, when qualified, Clinical Clerks to the several physicians; the pupils attending the Surgical practice may become, when qualified, clinical clerks to the several Surgeons. Pupils entering to the Surgical practice for twelve months are allowed, when qualified, to dress the patients for three months, and perpetual pupils for six months, without additional fee. The perpetual pupils are eligible to be Assistant House-Surgeon for six months and House-Surgeon for twelve months (without additional fee), when properly qualified for the office. The Library and Reading-room are open during the greater part of the day. Subscription for the first year, 1 guinea, and 5 shillings for every subsequent year. The Museum is open daily to the pupils of the Hospital.

Students may compound, by payment of 50*l*., for admission to all the lectures required by the regulations of the College of Surgeons and Society of Apothecaries, (Practical Chemistry excepted) or by payment of 55*l*. for perpetual admission to all the Lectures, (Practical Chemistry excepted.) Such students will be required to pay a matriculation fee of 10s.

Examinations of those students who are Candidates for Prizes and Certificates of Merit will take place at the end of each Course.

There will be examinations for two Scholarships in April, 1850.

Further information may be obtained from any of the Lecturers, or from Mr. Hammerton, the Apothecary of the Hospital, who is authorised to enter the names of students.

THEATRE OF ANATOMY AND MEDICINE, No. 1, GROSVENOR-PLACE. ADJOINING SAINT GEORGE'S HOSPITAL. SESSION 1849-50.

Hospital Practice.—Table of fees for attendance upon the medical and surgical practice of St. George's Hospital:—Medical, six months, 8 guineas; twelve months, or time required by Examining Boards, 16 guineas; perpetual, 25*l*. 5s.; surgical, 15 guineas; twelve months, or time required by Examining Boards, 21*l*.; perpetual, 52*l*. 10s; apothecary's fee for students entering to the medical practice one guinea. All students entering to the hospital practice are entitled to attend the Clinical Lectures there delivered; and also to become house-surgeons and dressers when qualified, without the payment of an extra fee. The library and reading-room are open to all students of the hospitals upon payment of the usual fee. Medals or prizes, and honorary certificates, will be awarded in each class, and publicly presented on Wednesday, May 1st, 1850, at half-past two. Clinical prizes:—Prizes will be awarded by the lecturers of this school, for the best Reports of medical and Surgical cases occurring in the wards of St. George's Hospital; the competition for which will be open to all the students of the hospital. The microscope will be used to illustrate particular subjects in the lectures upon anatomy, chemistry, and botany. The dissecting-room and Museum are open to the students during day-light, where their studies will be superintended by the lecturers on anatomy, and by the anatomical tutors, from ten to half-past three o'clock. General fee to the whole of the courses required by the Royal College of Surgeons of England, and the Apothecaries' Company, including one course of practical chemistry, 42 guineas; half of which may be paid on the entrance of pupils, and the remaining half in January, at the commencement of the second division of the course. Further particulars respecting the school may be obtained at the Theatre, 1, Grosvenor-place, or at the residence of the Honorary Secretary, Dr. W. V. Pettigrew, 7, Chester-street.

WESTMINSTER HOSPITAL SCHOOL OF MEDICINE.—SESSION 1849-50.

The session will commence on Monday, Oct. 1st, 1849, with an introductory lecture, at 4 p.m., by Dr. Hamilton Roe.

Hospital Practice, daily from 12 to 2.—Consulting Physician, Dr. Bright; Physicians, Dr. Hamilton Roe, Dr. Kingston, Dr. Basham; Consulting Surgeon, Mr. Guthrie; Surgeons, Mr. Lynn, Mr. Hale Thomson, Mr. Benjamin Phillips; Assistant-Surgeon, Mr. Barnard Holt. Clinical lectures will be delivered regularly, twice a-week, by the Physicians and Surgeons. *Post mortem* examinations will be made under the superintendence of the Physicians and Surgeons; on which occasions, pathological demonstrations will be given, to illustrate the structural changes effected by disease.

Fees for Attendance.—Medical Practice: Six months, 10 guineas; twelve months, 12 guineas; eighteen months, 15 guineas; perpetual, 20 guineas. Surgical Practice: three months, 8 guineas; six months, 12 guineas; twelve months, 20 guineas; perpetual, 30 guineas. Conjoint fee for the period of hospital practice required by the Royal College of Surgeons and the Society of Apothecaries, 26 guineas.

Maternity Charity.—Physicians, Dr. Frederick Bird and Dr. W. Merriman; Surgeon, Mr. Greenhalgh. This Charity affords attendance to 500 lying-in patients annually. Clinical lectures will be delivered by Mr. Greenhalgh.

General fee to all the lectures required by the Royal College of Surgeons and Society of Apothecaries, 40 guineas, exclusive of practical chemistry. The fees are to be paid to the Secretary of the Hospital, who will issue tickets of admission to the courses, which must be subsequently counter signed by the Lecturers. Clinical Assistants, Clinical Clerks, and Dressers, will be selected from the best qualified students without extra fee. Certificates of honour in all the classes will be awarded at the end of each session. Further particulars may be obtained by application to the Physicians and Surgeons, the Lecturers, or to F. J. Wilson, Secretary of the Westminster Hospital.

CHARING-CROSS HOSPITAL.—MEDICAL SCHOOL, LONDON. WEST STRAND, NEAR CHARING-CROSS. SESSIONS 1849—1850.

Hospital Practice.—Physicians—Dr. Shearman, Dr. Golding, Dr. Chowne. Surgeons—Mr. Hancock, Mr. Avery.

Medical Practice—Six months, 10 guineas; full period required, 15 guineas. Surgical Practice—Six months, 10 guineas; full period required, 15 guineas. Full period required, to both Medical and Surgical Practice, 25 guineas.

The Physicians and Surgeons visit the wards, on

their respective days, between one and two o'clock. The cases in the out-patients' department are seen and prescribed for at the Hospital daily, between twelve and two o'clock. Clinical Lectures—Medical and Surgical Clinical Lectures are given weekly, by the Physicians and Surgeons of the Hospital. Practical Pathology — *Post-mortem* Examinations are performed in available cases. The Museum contains numerous instructive preparations of morbid and natural structure; together with a cabinet of Materia Medica, models, casts, drawings, diagrams, &c., for illustrating the various lectures. A gold medal, and other medals and testimonials of honour, are presented publicly to the successful candidates early in May, after the termination of the session. Diligence and regularity of attendance on the practice and classes are expected, as a preliminary qualification for the competition.

Certificates of attendance at this Hospital and School qualify for examination, on the respective subjects, at the University of London, Royal College of Surgeons, and Society of Apothecaries.

General fee, for all the lectures required by the College of Surgeons and Society of Apothecaries, 42 guineas; without Practical Chemistry, 40 guineas.

HUNTERIAN SCHOOL OF MEDICINE,
No. 1, BEDFORD STREET, BEDFORD-SQUARE.
ESTABLISHED IN 1822, BY THE LATE MR. DERMOTT.
SESSION 1849–1850.

For all the lectures required by the Royal College of Surgeons, Apothecaries' Hall, &c., 32 guineas. Hospital practice, both medical and surgical, together with the above lectures, 57 guineas. The different courses of lectures will be illustrated by preparations; recent specimens of diseased structure; a Hortus Siccus, and microscopes, with anatomical and pathological drawings. There will also be an ample supply of midwifery patients. Medical officers of the army and navy, and the East India Company's service, and missionaries, are permitted to attend gratuitously the whole of the public lectures delivered at this school. A private class will be established for preparing students to pass the different Examining Boards. Terms, five guineas. The private instruction will be undertaken by the tutors. Assistant Navy surgeons can prosecute private courses of operative surgery, and receive private instruction upon regional anatomy, preparatory to their examination for full surgeoncy, in accordance with the late regulations of the Admiralty. Resident house pupils are free to all the lectures delivered in the establishment,—have the privilege of attending all the courses of private instruction, besides receiving especial private aid and direction in the pursuit of their studies; also dissection, and consequently ample opportunities for acquiring a thorough knowledge of every branch of the Profession. They have also the choice of attending the Western, Farringdon, and Surrey Dispensaries, and the Metropolitan Free Hospital, all which Institutions are recognised. Out-door and in-door apprentices have opportunities for acquiring theoretical and practical knowledge in every branch of the profession. Their indentures are so arranged as to serve for passing the examinations, both at the College of Surgeons and Apothecaries' Hall; and the full curricula of study guaranteed for the degree of Doctor of the University of London, the London College of Physicians, and the diploma of the College of Surgeons. They have also the privilege of attending all the courses of private instruction, besides that of having special private tutorage. The widow of the late Mr. Dermott has an interest in the school. Prospectuses of the school, and any further information, may be had by application to Dr. Aldis, 1, Chester terrace, Chester-square; and at 28, Bedford square; or to any of the lecturers.

ROYAL COLLEGE OF CHEMISTRY, OXFORD-STREET, LONDON.

The practical course of instruction in this Institution is under the direction of Dr. A. W. Hofmann and assistants. The next session will commence on Monday, the 1st of October next, and end on Saturday, the 23rd of February, 1850. The fee for students working every day during the session is 15*l.*; for four days in the week, is 12*l.*; for three days in the week, is 10*l.*; for two days in the week, is 7*l.*; for one day in the week, is 5*l.* Hours of attendance from nine to five. Further particulars may be obtained on application to the Secretary, Mr. William Johnson.

LONDON CUTANEOUS INFIRMARY.
Established 1841.

The medical and surgical practice is open to practitioners and students. A fee of five guineas (applied towards the support of the Charity) admits to an unlimited attendance, and also to Mr. Startin's lectures on diseases of the skin, a course of which will commence in October next, and be extensively illustrated by cases in attendance and wax models. 21,760 cases of cutaneous diseases are now registered on the books of the Infirmary, and the annual number of patients averages 7000. Further particulars may be obtained on application to Thomas Bowen, Resident Dispenser, 25, Bridge-street, Blackfriars.

SCOTLAND.
UNIVERSITY OF EDINBURGH (1582).

Matriculation.—Every students in the faculties of arts, law, and medicine, before entering with any Professor, must produce a matriculation ticket for the ensuing session. Tickets will be issued at the matriculation office, in the Colleges, every lawful day, from ten till three. Enrolment in the general album is the only legal record of attendance in the University.

Library.—The library will be open for the purpose of giving out books to students, either on loan or for reference, in the hall appropriated for that purpose, every lawful day during the winter session, from ten a.m. till four p.m., except on Saturdays, when it will be shut at one precisely.

Every student applying for books must present to the Librarian his matriculation ticket for the session, with the ticket of at least one Professor.

Every book taken out must be returned within a fortnight, uninjured.

Fee for each course, 4*l.* 4*s.* For graduation, 25*l.*

Statutes of the University of Edinburgh Relative to the Degree of M.D.

Sect. I. No one shall be admitted to the examinations for the degree of doctor of medicine who has not been engaged in medical study for four years, during at least six months of each, either in the University of Edinburgh, or in some other University where the degree of M.D. is given; unless, in addition to three Anni Medici in a University he has attended during at least six winter months, the medical or surgical practice of a general hospital, which accommodates at least eighty patients, and during the same period a course of practical anatomy in which case three years of university study shall be admitted.

Sect. II. No one shall be admitted to the examinations for the degree of doctor who has not given sufficient evidence—1. That he has studied, once at least, each of the following departments of medical science, under professors of medicine, in this or some other university, as already defined,—viz.:—

During Courses of Six Months.—Anatomy, chemistry, materia medica, and pharmacy institutes of medicine, practice of medicine, surgery, midwifery, and the diseases peculiar to women and children, general pathology, practical anatomy (unless it has been attended in the year of extra-academical study allowed by Sect I.)

During Courses of Six Months or Two Courses of Three Months.—Clinical medicine, that is, the treatment of patients in a public hospital, under a professor of medicine, by whom lectures on the cases are given.

During Courses of at least Three Months.—1. Clinical surgery, medical jurisprudence, botany, natural history, including zoology. 2. That in each year of his academical studies in medicine he has attended at least two of the six months' courses of lectures above specified, or one of these and two of the three months' courses. 3. That besides the course of clinical medicine already prescribed, he has attended, for at least six months of another year, the medical or surgical practice of a general hospital, either at Edinburgh or elsewhere, which accommodates not fewer than eighty patients. 4. That he has attended for at least six months, by apprenticeship or otherwise, the art of compounding and dispensing drugs at the laboratory of a hospital, dispensary, member of a Surgical College or Faculty, Licentiate of the London or Dublin Society of Apothecaries, or a professional chemist or druggist. 5. That he has attended for at least six months, by apprenticeship or otherwise, the out-practice of a hospital, or the practice of a dispensary, or that of a physician, surgeon, or member of the London or Dublin Society of Apothecaries.

Sect. III. No one shall obtain the degree of Doctor who has not studied, in the manner already prescribed, for at least one year previously to his graduation, in the University of Edinburgh.

Sect. IV. Every candidate for the degree in medicine must deliver, before the 24th of March of the year in which he proposes to graduate, to the Dean of the Faculty of Medicine—1. A declaration, in his own handwriting, that he is twenty-one years of age, or will be so before the day of graduation, and that he will not be then under articles of apprenticeship to any surgeon or other master. 2. A statement of his studies, as well in literature and philosophy as in medicine, accompanied with proper certificates. 3. A medical dissertation, composed by himself, in Latin or English, to be perused by a professor, and subject to his approval.

Sect. V. Before a candidate be examined in medicine, the medical faculty shall ascertain, by examination, that he possesses a competent knowledge of the Latin language.

Sect. VI. If the faculty be satisfied on this point, they shall proceed to examine him, either *vivâ voce* or in writing—1. On anatomy, chemistry, botany, institutes of medicine, and natural history, bearing chiefly on zoology; and, 2. On materia medica, pathology, practice of medicine, surgery, midwifery, and medical jurisprudence.

Sect. VII. Students who profess themselves ready to submit to an examination on the first division of these subjects, at the end of the third year of their studies, shall be admitted to it at that time.

Sect. VIII. If any one, at these private examinations, be found unqualified for the degree, he must study, for another year, two of the subjects prescribed in Section II., under Professors of Medicine, in this or in some other University, as above defined, before he can be admitted to another examination.

Sect IX. Should he be approved of, he will be allowed, but not required, to print his thesis; and, if printed, forty copies of it must be delivered, before the 25th day of July, to the Dean of the Medical Faculty.

Sect. X. If the candidate have satisfied the Medical Faculty, the Dean shall lay the proceedings before the Senatus Academicus, by whose authority the candidate shall be summoned, on the 31st of July, to defend his thesis; and, finally, if the Senate think fit, he shall be admitted, on the first lawful day of August, to the degree of Doctor.

Sect. XI. The Senatus Academicus, on the day here appointed, shall assemble, at ten o'clock, a.m., for the purpose of conferring the degree; and no candidate, unless a sufficient reason be assigned, shall absent himself, on pain of being refused his degree for that year.

Sect. XII. Candidates for graduation shall be required to produce evidence of their having conformed to those regulations which were in force at the time they commenced their medical studies in a university.

UNIVERSITY OF GLASGOW.

Regulations regarding Degrees in Medicine and Surgery to Candidates entering the University in, or subsequent to, 1839 40.

Medicine.—Every candidate for a medical degree must lodge with the Clerk of Senate—

1. A certificate of moral character, by two re-

spectable persons, with evidence of having attained the age of twenty-one.

2. Evidence of having attended, for four years, university in which medicine is regularly taught, or medical lectures delivered in London or Dublin and at least one year of the four must be spent at the University of Glasgow. In each year, he must have attended at least two courses of lectures of six months' duration; but if he shall spend one year only at the University of Glasgow, then he must attend three courses of lectures delivered there two of them, at least, being of six months' duration.

3. Certificates of having attended one or more courses of lectures on the following subjects, each course, except forensic medicine and botany, being of six months' duration; if of less extent, then two courses shall be deemed equivalent to one of six months:—Anatomy and physiology; chemistry, the theory or institutes of medicine; practice of medicine; materia medica and pharmacy; midwifery; surgery; forensic medicine; botany (a); anatomical dissections; and two years' practice of a general hospital, containing eighty beds, and in which the student must spend at least one-half of the period of attendance in the physicians' wards. Neither hospital attendance nor anatomical dissections shall be considered as equivalent to a course of lectures.

4. Each candidate must lodge with the clerk of Senate, with the above certificate, a schedule of his course of study, properly filled up, together with an English essay on some medical subject chosen by himself, two months before the time of graduation—that is, on or before the 1st of March or the 10th of June, yearly—otherwise he cannot be admitted for examination till the following term. All tickets of attendance lodged by candidates must be certified, not excepting those of the current session; but the certified botanical tickets of the current session shall not be received until the 1st of April.

5. No student entered in any medical class later than the 1st of December, without special permission of the senate. And it is strictly required of every candidate for graduation that he produce evidence of his name having been enrolled in the library book, on or before that day, as well as an express certificate of his regular attendance by each Professor on whose lectures he attends. In order, further, to insure attendance, all students must inscribe their names, once a fortnight, in a register kept for the purpose, stating the lectures, &c., which they attend.

6. Every candidate shall prove that he has a competent knowledge of Latin, and shall undergo full examinations on all the subjects included in the curriculum.

Surgery.—The regulations respecting certificates of age and moral character are the same as those under the head of degrees in medicine.

Candidates for the degree of master of surgery shall produce evidence that they have attended medical lectures in one or other of the universities or schools already specified for four years, during which they must have attended one or more courses on the following subjects, the extent of each course, with the exception of forensic medicine, being six months, or the equivalent two courses of a shorter duration. The candidate must have attended not less than three courses of medical lectures in the University of Glasgow. In each year of his study he shall have attended at least two or more courses of lectures, of six months' duration, on anatomy, surgery, chemistry, theory or institutes of medicine, practice of medicine, midwifery, materia medica and pharmacy, forensic medicine, anatomical dissections, and two years' practice of a general hospital, in which the student must attend one half of the prescribed period in the surgical wards, and the other half in the medical.

The regulations as to lodging certificates of attendance, and an essay in English, and as to the candidate's knowledge of Latin, are the same as under the head of medical degrees, only the essay is to be on a surgical subject. The days of graduation are the last Wednesday of April and the first Wednesday of August.

Fee to the library, &c., for the degree of M.D.	£15 0 0
Duty on stamp for ditto . .	10 3 0
	£25 3 0
Fee for the degree of Chirurgiæ Magister	£10 10 0

N. B. Candidates for degrees who attended classes in the University of Glasgow previously to 1839 40, admitted to examination according to the regulations which existed at the time when they began to study medicine.

(a) No course of botany attended previously to 1839-40 is received, unless it shall have been delivered in a university.

UNIVERSITY OF ST. ANDREWS. (1412.)

Regulations for Granting Medical Degrees.—The candidate must produce evidence of unexceptionable moral character, and before being admitted to examination must subscribe a declaration that he is twenty-one years of age.

The candidate must have had a liberal classical education, and, if he be not in the possession of the degree of A.M., must be ready to undergo an examination as to his proficiency in the Latin language.

The candidate must produce certificates that he has regularly attended lectures delivered by Professors in some University, or by resident fellows of the Royal Colleges of Physicians or Surgeons of London, Edinburgh, Glasgow, Aberdeen, or Dublin, for at least four complete winter sessions, or three winter and three summer sessions, on the following branches:—1, anatomy, two courses of six months each; 2, practical anatomy, twelve months; 3, theory of medicine, or physiology, one course of six months; 4, chemistry, one course of six months; 5, practical chemistry, one course of three months; 6 materia medica and pharmacy, one course of six months; 7, surgery, one course of six months; 8, clinical medicine, one course of six months; 9, practice of medicine, one course of six months; 10, clinical surgery, one course of six months; 11, midwifery and diseases of women and children, one course of three months; 12, an apprenticeship, or six months' attendance in the shop of an apothecary, or in the laboratory of a public hospital or dispensary; 13, attendance at a public hospital, containing not less than eighty beds, for at least eighteen months.

These regulations will be invariably observed, except when the candidates are possessed of a surgeon's diploma or license from the Colleges of London, Edinburgh, or Dublin, or the Faculty of Physicians and Surgeons of Glasgow, or a licence from the Apothecaries' Company, in which case they have merely to present such diploma or license previous to their examination for M.D.

KING'S COLLEGE, ABERDEEN.

Regulations to be observed in granting Degrees in Medicine at King's College.

All Candidates for the degree of M.D. must be of the age of twenty-one years, and must produce satisfactory certificates of moral character, and exhibit the diploma of A.M. from some University.

All candidates, with the exceptions mentioned below, must have been engaged in the study of medicine for, at least, four years, one of which must be passed in Aberdeen, and must produce evidence of having attended, in some recognised school of medicine, the following courses of lectures:— Six months' courses: anatomy, two courses; chemistry, one course; materia medica, one course; surgery, one course; institutes of medicine and physiology, one course; practice of medicine, one course; midwifery, one course. Three months' courses: dissections, two courses; practical chemistry, one course; medical jurisprudence, one course; clinical surgery, one course; botany, one course; clinical medicine, two courses.

In addition to the above, the candidate must have attended, for two years, the wards of a hospital containing 100 beds; and, during three months, a shop, or dispensary, for the compounding of medicine.

The preceding regulations are strictly enforced in the case of all students who shall commence their medical studies at a period subsequent to October 1, 1840. But gentlemen who possess a licence, or diploma, from any of the Royal Colleges of Physicians or Surgeons, and who have been engaged for, at least, five years in the practice of medicine, may be admitted to examination on producing their license, or diploma, along with satisfactory evidence of sufficient preliminary education and of good moral character.

Previously to examination each candidate must lodge with the Secretary 26*l.* 5s. 6d., the same to be returned to him should he not obtain his degree.

Degrees in medicine are conferred at two stated periods annually—viz., at the end of April, and at the end of July.

REGULATIONS FOR GRANTING MEDICAL DEGREES IN MARISCHAL COLLEGE AND UNIVERSITY, ABERDEEN.

Curriculum.—Four years of attendance on medical classes, of which one year may be passed at any recognised medical school; but three, at least, must be passed in a university, including one, at least, in this university. The attendance in each year to embrace not fewer than two medical classes of six months each; or one of six months, with two of three months each. But it will be held equivalent to *one* of four years of such attendance in a university—1st, in a master of arts, to have attended one medical class while passing through the curriculum of arts; or, 2ndly, in any student to have attended a medical class, in each of two years, along with classes in the curriculum of arts. The university attendance to include the following eight classes, each for a course of six months:—Anatomy, practical anatomy, chemistry, materia medica, institutes of medicine, surgery, practice of medicine, midwifery; and the following three classes, each for a course of three months—botany, practical chemistry, and medical jurisprudence.

Eighteen months of attendance on the medical and surgical practice of a hospital containing not fewer than eighty beds, along with attendance for six months on lectures on clinical medicine, and for three months on lectures on clinical surgery.

Six months of compounding and dispensing medicines in the laboratory of a hospital, or of a public dispensary, or of a licensed general practitioner, or of a regular dispensing druggist.

Exemption to Practitioners.—It will be held equivalent to the curriculum prescribed in the three foregoing regulations to have obtained, upon examination, a diploma or a license, in medicine or in surgery, from a university or other authority established by law within the United Kingdom, and to have subsequently attended medical classes in this University during one winter session.

Examinations.—The examination terms to be two in each year,—the *first* to commence on the 20th of April, if a Wednesday, but if not, on the first Wednesday thereafter; the *second* on the 20th of October, if a Wednesday, but if not, on the first Wednesday thereafter.

Every candidate to undergo at least three separate professional examinations: the first, pharmaceutical; the second, surgical; the third, medical; to be conducted partly in writing, as well as *vivâ voce*, and partly by demonstration. The *first* to include chemistry, botany, materia medica, pharmacy, and the doctrines of physics relating to specific gravities, to gases and vapours, and to climate. The *second* to include anatomy, institutes of medicine, surgery, and the doctrines of chemistry and physics illustrative of animal structure and function. The *third* to include the practice of medicine, midwifery, and medical jurisprudence.

Every candidate not a Master of Arts must undergo a preliminary examination on the Latin language, (the book to be used being "Celsus de Medicinæ,") and on the etymology of such terms in the medical sciences as are derived from the Latin and the Greek.

Any candidate that so desires shall be admitted to each one, or to any two, of his three professional examinations, at different terms; but not to the

first examination until the beginning of his third year of medical classes; nor to the second until the end of his third year; nor to the third until the end of his fourth year, and until he be 21 years of age; nor shall a greater interval than eighteen months be allowed between two successive professional examinations without a full renewal of the previous one or two. The preliminary examination must be passed at the same term as the first professional examination.

In order to be received for examination, certificates must have been lodged with the Professor of Medicine on the first day of the month of the examination term, showing that the candidate is of the required age, that he is of good moral character, and that he has passed through the requisite course of professional education. Along with such certificates must be lodged a schedule, filled up in his own handwriting, containing a list of them, and specifying such additional branches of education, professional and general, as he may have studied.

ROYAL COLLEGE OF PHYSICIANS, EDINBURGH.

The members of the College are respectively entitled Fellows, Non-resident Fellows, and Licentiates.

Ordinary Fellows.—No one shall be elected an ordinary Fellow of the College till he has obtained the degree of doctor of medicine.

Every motion for the election of a Fellow shall be made, at a quarterly meeting, by one of the Fellows present, seconded by another, and determined by ballot—a majority of three-fourths being necessary to carry it in the affirmative.

No physician residing in Edinburgh shall be proposed for a resident Fellowship till he has been a licentiate for nine months, or, in case of his not being a licentiate, till nine months after his petition to be admitted a resident Fellow shall have been presented, unless an urgent reason be assigned; in this case, he may be proposed even on the same day on which he becomes a licentiate, or at any other quarterly meeting, or at a meeting specially called for the purpose, if this proposal shall be agreed to by every member present.

No Fellow shall engage himself to any candidate before the ballot; nor shall he reveal to any person in what manner he did ballot, under the pain of being considered as one who has broken his faith and honour to the College.

No Fellow shall take his seat in the College till the quarterly meeting after that on which he is elected, intimation to attend being then sent to him by the Clerk.

The Fellows shall be placed on the roll according to the dates of their admissions; and, when two or more Fellows are admitted on the same day, they shall be entered on the roll according to the dates of their diplomas; and, if their diplomas be of the same date, they shall be enrolled according to their ages.

Every Fellow, before taking his seat in the College, must sign a promissory engagement.

Graduates of Foreign Universities must previously submit to an examination, which can only be dispensed with by an unanimous vote of the College upon a motion made by a Fellow, of which due notice requires to be given.

If an examination shall take place, it shall consist of three trials: the first, by two Fellows appointed by the College, on any part of Medicine; the second, by two other Fellows, on two aphorisms of Hippocrates; and the third, by two other Fellows, on two medical cases. All these trials shall be in the presence of the College, and in the Latin language.

Non resident Fellows.—No physician residing in Edinburgh is eligible for a non-resident fellowship.

The mode of election of a non-resident Fellow is the same as that of a resident fellow; and the laws regarding examination, in the case of a foreign degree, also apply to him.

Fees.—The fee to be paid by a resident Fellow is about 130*l.*

The fee to be paid by a non-resident Fellow is 80*l.*

The fees are exclusive of any tax payable to the Government now existing, or which may hereafter be imposed.

ROYAL COLLEGE OF SURGEONS, EDINBURGH. (1505.)

Regulation for Fellows.—The candidate is required to present an essay on some surgical subject, which, if approved of, he must print for circulation among the fellows. He must then undergo three examinations—1. On anatomy and surgery; 2. On chemistry, materia medica, &c.; 3. On the essay he has written. If these are satisfactorily passed, he is admitted to the fellowship. Fee, 250*l.*; to apprentices of fellows, 100*l.*

School of Medicine.—Every candidate for a surgical diploma must have followed the course of study, to be specified afterwards, in a university; or at the seat of an established school of medicine, as defined below; or in a provincial school, specially recognised by the College.

Under the title, established school of medicine, are comprehended all places in this kingdom where diplomas in surgery are granted, and such foreign schools as are acknowledged by the constituted authorities of the countries in which they exist.

The extent and period of study allowed to be gone through at a provincial school will be regulated by the means and facility of study which the College receive evidence of its affording; but the lectures delivered at a provincial school will be held as qualifying for only one year's course of study unless specially recognised for more.

Qualifications of Teachers.—The following classes of persons shall be entitled to give lectures, which may be attended as part of the course of study:—1. In the universities of Great Britain and Ireland, and in University College and King's College, London, the Professors of these Institutions. 2. In Edinburgh, resident Fellows o the Royal College of Physicians of Edinburgh and Fellows of the Royal College of Surgeons of Edinburgh. 3. In London, Fellows and Licentiates of the Royal College of Physicians of London, and members of the Royal College of Surgeons of London, whose status as teachers has been admitted by that College. 4. In Dublin Fellows of King's and Queen's College of Physicians in Ireland, and members of the Royal College of Surgeons in Ireland. 5. In Glasgow, members of the Faculty of Physicians and Surgeons of that city. 6. In recognised provincial schools, teachers whose status as such has been admitted by the College, on special application. 7. In any of the above schools, teachers who, having acquired a status as such in one of the four established schools, in conformity with the above regulations, shall have been subsequently admitted, on application to the College, to the enjoyment of the same privileges in another school. (a)

The following branches of instruction may be conjoined:—Anatomy and Practical Anatomy, Chemistry and Practical Chemistry, Practice of Medicine and Clinical Medicine, Practice of Surgery and Clinical Surgery, Mathematics and Mechanical Philosophy; and, for the present, Clinical Medicine or Clinical Surgery may be taught in conjunction with any one of the other courses of education prescribed in the curriculum, by a physician or surgeon qualified according to the regulations of the College, and attached to a public Hospital of the size which these regulations prescribe.

Course of Study.—*Preliminary Instruction.*—Every candidate for the diploma of the Royal College must, either previously to or during his medical education, have received regular instruction in the elements of mathematics; and must have subsequently attended a course of mechanical philosophy of at least three months' duration, and of not fewer than sixty lectures.

Professional Instruction.—The candidate must have been engaged in attending the following separate and distinct courses of lectures during a period of not less than twenty-seven months, in which must have been included three winter sessions of six months' duration each. Anatomy, two courses of six months each. Practical anatomy, twelve months. Chemistry, one course of six months. Practical chemistry (the number of pupils in each class being limited to twenty-five), one course of three months. Materia medica and pharmacy, one course of six months. Practical pharmacy, one course of six months. Institutions of medicine or physiology, one course of six months. Practice of medicine, one course of six months. Clinical medicine, one course of six months, or two courses of three months each, during the period of his attendance at the hospital where they are delivered. Principles and practice of surgery, two courses of six months each, or principles and practice of surgery and military surgery, one course of six months each. Clinical surgery, one course of six months, or two courses of three months each, during the period of his attendance at the hospital where they are delivered. Midwifery and diseases of women and children, one course of three months. Medical jurisprudence, one course of three months. Besides the above-mentioned course of lectures, the candidate must have attended a course of instruction in practical pharmacy, at the laboratory of a surgeon or apothecary; or of a chemist and druggist recognised by the College on special application; or of a public hospital or dispensary; and he must produce evidence that he has been engaged in compounding and dispensing medicines for the space of six months. Those who produce certificates of having been, for the space of at least two years, private pupils or apprentices to regularly licensed medical Practitioners, keeping laboratories for dispensing medicines, shall be exempted from attendance on this branch of instruction.

The six months' courses delivered in Edinburgh must consist of not fewer than 110 lectures, with the exception of clinical medicine, clinical surgery, and military surgery. The three months' courses must consist of not fewer than sixty lectures. Two London courses of three months each on any of the above subjects will be taken as equivalent to one six months' course.

The candidate must also have attended for twenty-one months a public general hospital containing at least eighty beds.

Fees payable by Candidates.—For a diploma, ordinary candidates pay the sum of 7*l.* 5s. (Apprentices of fellows of the Royal College, bound for the freedom, pay 25s.; their other apprentices pay 2*l.* 16s. 6d.) Assistant-surgeons in the navy, having previously obtained certificates from the College, pay 2*l.* 11s. 6d. Surgeons in the navy, having obtained certificates from the College, pay 15s. 6d.

For the certificate of qualification to act as assistant-surgeon in the navy, candidates not having paid for any previous qualification pay 4*l.* 19s. 6d.

For the certificate of qualification to act as full surgeon in the navy, assistant-surgeons who have already obtained certificates from the College pay 3*l.* 18s. 6d., and those who have previously obtained the diploma of the College pay 2*l.* 17s. 6d.

FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW.

Regulations for the Surgical Diploma.—The Faculty recommend that candidates should attend elementary courses of study in mathematics and natural philosophy. These branches, however, are not imperative. Every candidate's knowledge in Latin should be tested at his examination, by being required to construe some part of Gregory's "Conspectus Medicinæ Theoreticæ."

Curriculum.—Anatomy, two courses of six months. Practical anatomy, one course of six months; enacted 7th June, 1830. Surgery, two

(a) The only lectures excepted from this law are those on mechanical philosophy and on chemistry. The former may be Professors in universities, lecturers in public institutions, or teachers specially recognised by the College; and the latter may be persons not medical, if recognised by the College on special application, in conformity with a resolution of the College on the 25th October, 1838. In all cases of special recognitions, proof of capability, and of the applicant possessing the requisite apparatus for illustrating his lectures, will be required.

courses of six months. Chemistry, one course of six months. Practical chemistry, one course of three months; enacted 8th November, 1831. Theory of medicine, one course of six months. Practice of medicine, one course of six months. Materia Medica, one course of six months. Midwifery, one course of six months. Clinical medicine, one course of six months; enacted 7th June, 1830. Clinical surgery, one course of six months; enacted 7th June, 1830. Medical jurisprudence and police, one course of six months; enacted 4th April, 1841. Botany, one course of three months; enacted 3rd February, 1834. A public hospital, eighteen months; enacted 3rd February, 1834. A surgeon's or apothecary's shop, six months; enacted 3rd February, 1834.

The above lectures must have been delivered by Professors or Lecturers in a University; or by resident members of the Royal Colleges of Physicians or Surgeons respectively of London, Edinburgh, or Dublin; or by means of the Faculty. Every candidate must have been employed in the above course of studies for four winter sessions, or for three winter sessions and two summer sessions, so that the whole period of attendance shall not be less than three years complete. An essay, the subject to be fixed by the examiners, to be written by the candidate, in his own handwriting; and no essay to be submitted for a shorter period than two days. Specimens of bones, or other anatomical or surgical preparations, or specimens from the materia medica, shall be used at the discretion of the Examiners. The fee of seven guineas shall be deposited with the President previous to the examination, and, at the same time, satisfactory documents shall be produced that the above curriculum of education has been duly completed by certified attendance.

N.B. Those branches whose dates are specified are not required by those students who commenced their studies anterior to these enactments. The commencement of education is ascertained by the date of the first ticket.

The fees for the diploma are 7*l.* 7*s.* The President, Visiter, Collector, Box-masters, and Seal-keeper, form, along with the Assistant-Examiners, the examining Court. The diploma of the Faculty is recognised by all the licensing bodies in the three kingdoms, and by the Poor-law Commissioners in England and Ireland.

IRELAND.

UNIVERSITY OF DUBLIN (TRINITY COLLEGE). 1591.

Chancellor, His Majesty the King of Hanover; *Vice-Chancellor*, His Grace the Lord Primate of Ireland; *Provost*, Dr. Sadleir.

The days of graduation are, Shrove Tuesday, and the first Tuesday in July. The degree of bachelor of medicine may be obtained in two modes:—

1. Graduates in arts can obtain the degree at any of the half yearly periods of graduation, provided the requisite medical education and examination shall have been accomplished. Fee for entrance, 16*l.*; fees for study in arts during four years, 7*l.* 10*s.* each half year; fees for graduation in arts, 8*l.* 17*s.* 6*d.*

2. Candidates are admissible to the degree of M.B., without previous graduation in arts, at the end of five years from the July following the Hilary examination of the first undergraduate year, provided the usual education and examinations in arts for the first two years of the undergraduate course shall have been completed, as also the medical education and examinations, as in the case of other candidates. Fees for two years' study in arts (besides the usual entrance payment of 16*l.*) are 7*l.* 10*s.* each half year. The graduation fees for the degree of bachelor of medicine are 11*l.* 15*s.* The standing of the first undergraduate year may be obtained by attending the October examination of that year, if the student has entered not later than the first Monday of the July of the same year, and has completed the payments due since the ordinary period of entrance in the preceding November. The medical education of a Bachelor of Medicine comprises attendance on the following courses of lectures in the school of physic established by Act of Parliament, provided that one, and not more than three, of the courses which begin in November be attended during each of four sessions. Three of these courses, at the discretion of the candidate, may be attended at the University of Edinburgh. The courses are—on anatomy and surgery, chemistry, botany, materia medica and pharmacy, institutes of medicine, practice of medicine, midwifery (by the Professor to the College of Physicians), clinical lectures at Sir Patrick Dun's Hospital, during at least one session (six months), as delivered by the Professors in the school of physic; the attendance on such clinical lectures by the Professors to be extended to three additional months of a summer session commencing in May. This regulation to affect all students commencing their medical studies after 17th July, 1841, and to be in lieu of attendance on the hospital from 1st May to the 1st November following. The fees for attendance on the clinical lectures are 3*l.* 3*s.* to the Professors for each three months' attendance, and (provided the student be of two years' standing in the University) 3*l.* 3*s.* to the Treasurer of the Hospital for the first year, with a proportionate sum for any longer period. The fee for each of the other courses is 4*l.* 4*s.* The Examinations are conducted by the Regius Professors of Physic of the University, the six Professors of the School of Physic, and the Professor of Midwifery to the King and Queen's College of Physicians. No further examination is requisite for the degree of Doctor of Medicine, which may be taken at the expiration of three years from having taken the degree of M.B., provided the candidate shall have graduated in arts. The fees for the Degree of Doctor of Medicine are 22*l.* The Degrees are publicly conferred by the Vice-Chancellor, in the Senate or Congregation of the University.

College Terms.

Hilary begins	January 10,	ends	March 25.
Trinity ,,	April 15,	,,	June 30.
Michaelmas	October 10,	,,	December 20.

KING AND QUEEN'S COLLEGE OF PHYSICIANS IN IRELAND.

Qualifications of Candidates for Licence.—Candidates must produce evidence of having been engaged in the study of Medicine for four years, and of having attended two at least of the required courses in each year. Candidates, except those who have taken a Medical Degree, prior to 1840 must produce certificates of attendance on one or more courses of lectures on the following subjects, each course being of six months' duration, with the exception of botany and forensic medicine, which must include at least fifty lectures:—Anatomy and physiology, chemistry, materia medica and pharmacy, botany, institutes of medicine, practice of medicine, principles and practice of surgery, midwifery, and forensic medicine. The lectures on anatomy, chemistry, botany, materia medica, institutes of medicine, and practice of medicine are required to have been delivered by the respective Professors of the School of Physic in Dublin, or in a University. The lectures on surgery are required to have been delivered on at least three days in the week, during four months, by a Professor of Surgery in a University or College of Physicians or Surgeons in the United Kingdom, or by the Surgeon of a Medico-Chirurgical hospital recognised by the College. These lectures must not form a part of a course of lectures on anatomy. The lectures on midwifery are required to have been delivered by a Professor of Midwifery in a University or College of Physicians or Surgeons in the United Kingdom, or by the master of the Lying-in Hospital, Dublin. The lectures on medical jurisprudence are required to have been delivered by a Professor in a University or College of Physicians or Surgeons in the United Kingdom. Certificates must also be produced of six months' attendance on anatomical demonstrations and dissections, and of at least two years' hospital practice; one year in the hospital of the school of physic in Dublin or Edinburgh, the other in any recognised medico-chirurgical hospital. The certificates must include attendance on the entire practice of the hospital, and on all the clinical lectures delivered in the hospital during such attendance. Candidates who have taken a medical degree in a university shall be admitted to examination upon such degree alone. Every candidate for license, except those who have taken a medical degree prior to 1840, is examined on two separate days: on the first day, on anatomy and physiology, chemistry, botany, materia medica, and pharmacy; and on the second day, on acute and chronic diseases, midwifery, and non-naturals, and on the translating of one or more of the following books from the original Greek, viz.: Hippocrates, Aretæus, and Galen. Graduates in medicine are only required to undergo the second day's examination. The examinations, which are public, are conducted in the English language; but every candidate, except graduates in arts at Oxford, Cambridge, or Dublin, is required to translate medical cases from the English into the Latin language, before he is admitted to examination as to his professional acquirements. Fee for license, 30*l.*

The license of this College is equivalent to a medical degree, and it confers privileges which a degree does not.

The fellows are chosen from the licentiates of three years' standing; they are required by statute (10 Geo. III., cap. lxxxiv., sect. 42) to have taken the degree of M.D. in one of the Universities of Dublin, Oxford, or Cambridge; or to have taken the degree of A.B. in one of these Universities, and to have received the medical education requisite for obtaining the license, for which a degree in medicine is not necessary. Fee to the College on election to the fellowship 20*l.*, with an additional stamp duty of 25*l.*

The Act of Parliament provides that these qualifications may be dispensed with whenever, at any time, the number of fellows is reduced to six.

The College has the power of conferring the honorary fellowship on any of its own licentiates who have not the statutable qualifications; on such of its fellows as resign or vacate the fellowship; d on such eminent medical men, not licentiates, as it may wish to distinguish by its approbation.

ROYAL COLLEGE OF SURGEONS IN IRELAND. (1784—1828).

Bye laws respecting the Registry of Pupils.—Every person requiring to be registered as a pupil on the College books shall be so registered, if he shall have laid before the Court of Censors the following documents, viz.:—

Provided he be an apprentice, and shall have paid any apprentice-fee:—1. A receipt showing he has lodged, to the credit of the President and for the use of the College, in the Bank of Ireland, the registry fee of ten guineas. 2. A receipt showing that the member or licentiate to whom he is indentured has lodged a similar sum of ten guineas. 3. A declaration, subscribed by the member or licentiate to whom he is indentured, stating that he has really and *boná fide* received the usual fee of 150 guineas, or value to that amount. 4. His indenture of apprenticeship, duly executed, and bearing the requisite stamp.

Provided he be an apprentice, and shall not have paid an apprentice-fee, he shall lay before the Court—1. A declaration, subscribed by the member or licentiate to whom he is indentured, that he has not received, or that he does not expect to receive, any apprentice-fee. 2. A receipt, showing that he has lodged, to the credit of the President and for the use of the College, in the Bank of Ireland, the sum of fifty guineas. 3. His indenture of apprenticeship, regularly executed and registered.

Provided he be an apprentice, and be the son, brother, or nephew of the member or licentiate to whom he is indentured, or the son of some other member or licentiate of the College, and shall not have paid an apprentice-fee, he shall lay before the court—1. A declaration, subscribed by the member or licentiate to whom he is indentured, that he has not received, or that he does not expect to receive, any apprentice fee. 2. A receipt, showing that he has lodged, to the credit of the President, and for the use of the College, in the Bank of Ireland, the sum of ten guineas.

Provided he shall not be an apprentice to a

ber or licentiate of the College—1. A receipt, showing that he has lodged, to the credit of the President and for the use of the College, in the Bank of Ireland, the registry fee of ten guineas.

Bye-laws relating to Education and the Qualification of Candidates for Letters Testimonial.—Every registered pupil or apprentice shall be admitted to an examination for letters testimonial, if he shall have proved and showed that his professional education has been, in all respects conformable and agreeable to the provisions and enactments of the bye-laws and rules of the College, and shall have laid before the Court the following documents:—1. A receipt, showing that he has lodged, as a registry fee, the sum of ten guineas in the Bank of Ireland, to the credit of the President and for the use of the College previously to his being admitted to any examination. 2. A receipt, showing that he has lodged a sum of twenty guineas in the Bank of Ireland, to the credit of the President, and for the use of the College previous to his final examination for letters testimonial. 3. A certificate, signed by the President or Vice-President, and two of the Court of Censors that he has passed an examination as to his acquaintance with the Greek and Latin languages. 4. Certificates, showing that he has been engaged in the study of his Profession for not less than four years, three of which shall have been passed in attendance on lectures or Hospitals, during the winter sessions in Dublin, London, Edinburgh, or Glasgow. 5. Certificates of attendance on a surgical hospital where clinical instruction is constantly given, containing fifty patients at least, for a period of not less than twenty-four months. 6. Certificates of attendance on the medical practice of a recognised hospital or dispensary, where clinical instruction is constantly given during twelve months. 7. Certificates of attendance on three courses of lectures on anatomy and physiology, three courses of lectures on the theory and practice of surgery, and of the performance of three courses of dissections, accompanied by demonstrations; also certificates of attendance on two courses of lectures on chemistry, or one course of lectures on general, and one on practical, chemistry, one course of lectures on materia medica; one course of lectures on the practice of medicine; one course of lectures on midwifery, and one course of lectures on medical jurisprudence. 8. A thesis, essay, or dissertation, in Latin or English, on any of the following subjects:—Anatomy, physiology, surgery, the practice of medicine, chemistry, materia medica, midwifery, or medical jurisprudence; or, in the place of such dissertation, a series of cases collected in the hospital in which the candidate has attended, illustrated by comments or observations.

A candidate, being a registered pupil, shall be allowed to pass the first of the two days' examination above mentioned, on anatomy and physiology, on laying before the Court of Censors the following documents:—1. A receipt, showing that he has lodged a sum of ten guineas in the Bank of Ireland, to the credit of the President and for the use of the College. 2. Certificates, showing that he has been engaged in the study of his profession for not less than three winter sessions in Dublin, London, Edinburgh, or Glasgow. 3. Certificates of attendance on three courses of lectures on anatomy and physiology, and of the performance of three courses of dissections, accompanied by demonstrations; such candidate not being admissible to the second day's, or the final examination, on the other subjects above specified, until he shall have lodged a further sum of ten guineas in the Bank of Ireland, to the credit of the President and for the use of the College, and shall have laid before the Court of Censors all the documents enumerated in the bylaws relative to "qualifications for the letters testimonial." Notice of every examination for letters testimonial is posted in the Hall, and the Secretary also, by regular summonses, gives notice of such examination to the members resident in Dublin. The examination takes place in the presence of such members and licentiates as choose to attend. The candidate is examined on two several days in anatomy and physiology, on the practice of medicine and surgery, and on any other branch of medical science, and shall perform such surgical operations or dissections, and explain such anatomical preparations, as the Court may require.

Fee for letters testimonial or diploma, 31*l*. 10*s*. and for admission as member, (which takes place by ballot after three years' standing as a licentiate, and confers corporate rights,) 31*l*. 10*s*.

APOTHECARIES' HALL OF IRELAND. 1791.

Laws Regarding the Education of Apothecaries.—Every candidate must undergo two separate examinations—one for the certificate of apprenticeship, the other for the licence to practise.

Every candidate for the certificate of apprenticeship must have attained the age of fifteen years, and will be examined in the following books?—The works of Sallust; the first six books of the Æneid of Virgil; the Satires and Epistles of Horace; the Greek Testament; the Dialogues of Lucian; the first four books of Homer's Iliad; the first six books of Telemachus, or the History of Charles the Twelfth (in French); the first two books of Euclid and algebra—to simple equations.

Every candidate for the licence to practice as an apothecary must lay before the Court the following documents:—1. The certificate of apprentice. 2. The indenture of apprenticeship, enrolled according to the Act of Parliament, bearing the certificate of the licentiate apothecary to whom he has been indented, that he is of good moral character, and has fulfilled the period of his apprenticeship. 3. Certificates duly signed that he has diligently attended at least one course of lectures on each of the following subjects, delivered at the school of Apothecaries' Hall or at some other school of medicine recognized by the Court (the order of the study here laid down is recommended for the guidance of students):—Chemistry, anatomy, and physiology, six months; practical chemistry and botany, three months; materia medica, demonstrations, and dissections; theory and practice of physic, surgery, midwifery and the diseases of women and children, six months; medical jurisprudence, three months.

A certificate of twelve months' attendance on the entire practice of a medico-chirurgical hospital, recognized by the Court, containing not less than fifty beds, and where clinical instruction is regularly given.

Also, a certificate of having assisted in at least thirty cases of midwifery practice, twenty of which must be attended in a recognized hospital.

The examination for the licence to practise as an apothecary will be as follows:—In translating and explaining the process of the British Pharmacopœias and extemporaneous prescriptions; in chemistry and general physics; in materia medica and therapeutics; in natural history and medical botany; in anatomy and physiology; in the theory and practice of medicine; in midwifery; in medical jurisprudence.

The examination for the licence to act as assistant to an apothecary in compounding and dispensing medicine will be confined to the following subjects:—To translate the Dublin Pharmacopœia, and extemporaneous prescriptions; pharmacy, botany, materia medica, and mechanical philosophy.

The candidate for the assistant's licence may present himself for examination at the termination of five years' apprenticeship.

The Court of Examiners sit every Friday, at two o'clock, and proceed with the examination of candidates in the order in which their names appear on the list.

A rejected Candidate cannot be re-admitted to examination until the expiration of six months, and, after a second rejection, can appeal to be examined by the King and Queen's College of Physicians.

All lecturers are required to furnish the Court of Examiners with a list of such gentlemen as have taken out admission tickets on or before the 1st day of January; also a similar list of those who have obtained certificates of having attended their respective courses, with the number of lectures in each course, on or before the 10th of May, annually.

REGULATIONS OF THE ARMY MEDICAL DEPARTMENT, 13, ST. JAMES'S-PLACE.

A candidate for an Assistant Surgeoncy in the army is required to fill up a blank form of certificate, which may be obtained at the office by written application to the Director General, specifying by whom he is recommended, his Christian and surname at full length, with the course of study he has pursued. The candidate is, in addition, to sign and forward the following declaration:—

"I [Christian and surname at full length] —— years of age, a candidate for employment in the medical department of the army, do hereby attest my readiness to engage for general service, whether at home or abroad, and to proceed on duty immediately on being gazetted. I declare my age not to exceed twenty-six years, that I am unmarried, and that I labour under no mental or constitutional disease, nor physical disability, that can interfere with the most efficient discharge of the duties of a medical officer in any climate." [Signature.]

In selecting from among the candidates for the medical department of the army, a preference is given to those who can fill up all the blanks in the printed form; but the name of no gentleman can be placed on the list who does not possess the diploma of either of the Colleges of Surgeons of London, Edinburgh, or Dublin, and who cannot produce the following testimonials:—Eighteen months' attendance at an hospital of celebrity, where the average number of in patients is not less than one hundred; twenty-four months' anatomy; twelve months' practical anatomy; twelve months' surgery, or (what is preferred) six months' surgery, and six months' military surgery; eight months' clinical surgery, a complete course of two or three lectures during the week; twelve months' practice of physic, or six months of practice of physic, and six months of general pathology; eight months' clinical lectures on ditto, the same as required in surgery; twelve months' chemistry; six months' practical chemistry; three months' botany; four months' materia medica; three months' practical pharmacy, or apprenticeship; five months' natural history; five months' midwifery; five months' natural philosophy.

The candidates must be unmarried, not beyond twenty-six years of age, nor under twenty-one years.

Candidates who have had a university education, and have the degree of A.B. or A.M., as well as that of M.D., will be preferred; but a liberal education, and a competent knowledge of the Greek and Latin languages, are indispensably requisite in every candidate; and the greater the attainments of the candidates in various branches of science, in addition to competent professional knowledge, the more eligible will they be subsequently deemed for promotion in the service; for selections to fill up vacancies will be guided more by reference to such acquirements than to mere seniority. Before promotion from the rank of assistant-surgeon to any higher rank, every gentleman must be prepared for such other examination as may be ordered before a board of medical officers.

Although the British schools are specified, it is to be understood that candidates who have received regular education in approved foreign universities or schools will be admitted to examination.

With the exception of practice of physic and clinical medicine by one teacher, candidates must have attended separate lectures for each branch of the science. The certificate of each teacher of practical anatomy must state the number of subjects or parts dissected by the pupil. Certificates of lectures and attendance must be from physicians or surgeons of the recognised colleges of physicians and surgeons of the United Kingdom, or of foreign universities. A certificate that the candidate is acquainted with the art of cupping is required.

Diplomas, tickets of attendance on lectures, and certificates of regular attendance, by each professor, or lecturer, must be lodged at the office for examination and registry, at least one week before the candidate appears for examination, and likewise certificates of moral conduct and character, one of

them by a clergyman, and that of the parochial minister, are desirable. Baptismal certificates are required at the same time; if the parish register cannot be resorted to, an affidavit from one of the parents, or some person who can attest the fact, will be accepted.

All communications to be forwarded "unsealed," under cover, to "the Right Honourable the Secretary at War," with the words "Army Medical Department" at the corner.

Although, in the examination of candidates, gentlemen are expected to be qualified in every branch of study required, they are requested to be particularly conversant in the knowledge of—1. Tropical diseases, and the diseases to which soldiers are most liable. 2. Military surgery, and works on the habits of soldiers and rules of the service. 3. "Cullen's Nosology," being that adopted in all returns and reports. 4. "Willan's Classification of Cutaneous Diseases." 5. The latest authors on the diseases of the eye. They are expected readily to translate a passage from a Greek or Latin author; to be conversant with Baillie and the later authors on morbid anatomy; with Cullen's, Mason Good's, and Gregory's "Practice of Physic," the latter giving an account of tropical diseases, and those most commonly met with in the army; with the works of Hunter, Hennen, Dr. John Thomson, Guthrie, Samuel Cooper, Millengen, Ballingall, Marshall, and Baron Larrey, on "Military Surgery;" with the works of Chisholm, Bancroft, Lind, Blane, Burnett, Johnstone, and Annesley, on "The Diseases of Warm Climates;" but Baillie's "Morbid Anatomy," Hennen's and Ballingall's "Military Surgery," 3rd edition, with his valuable work on "Medical Topography," Guthrie on "Gunshot Wounds" and on the "Eye," and Gregory's "Practice of Physic," should form part of the baggage of every military surgeon.

Candidates, after passing their examination, will not have any leave of absence granted, but will be stationed at Chatham for two or three months, previously to being gazetted; and on their conduct there will depend their obtaining their commissions. The appointment of army assistant-surgeons rests with the Director-General, by whom the examinations are generally conducted.

NAVAL MEDICAL DEPARTMENT.
ADMIRALTY-OFFICE, SOMERSET HOUSE.

Director-General of the Medical Department of the Navy, Sir William Burnett, M.D., Knt., K.C.H., F.R.S.

Qualifications.—The Right Hon. the Lords Commissioners of the Admiralty having been pleased to direct "that no person be admitted as an assistant-surgeon in the Royal Navy, who shall not produce a certificate from one of the Royal Colleges of Surgeons of London, Edinburgh, or Dublin, of his fitness for that office; nor as a surgeon, unless he shall produce a diploma or certificate from one of the said Royal Colleges, founded on an examination to be passed subsequently to his appointment of assistant surgeon, as to the candidate's fitness for the situation of surgeon in the navy; and, in every case, the candidate producing such certificate or diploma, shall also undergo a further examination before the Director-General of the Medical Department of the Navy, touching his qualifications in all the necessary branches and points of medicine and surgery for each of the steps in the naval medical service," the Inspector-General doth hereby signify, for the information of those persons to whom it may relate, that these regulations and directions will be strictly adhered to; and further, that, previously to the admission of Assistant-Surgeons into the navy, it will be required that they produce proof of having received a preliminary classical education, and that they possess, in particular, a competent knowledge of Latin; also, that they are of good moral character, the certificate of which must be signed by the clergyman of the parish, or by a magistrate of the district. That they have served an apprenticeship, or have been engaged for not less than six months in practical pharmacy. That their age be not less than twenty years, not more than twenty-four, and that they are unmarried. That they have actually attended a hospital in London, Edinburgh, Dublin, Glasgow, or Aberdeen, for two years, after the age of eighteen, in which the average number of patients is not less than 150. That they have been engaged in actual dissections of the human body twelve months; the certificates of which, from the teacher, must state the number of subjects or parts dissected by the candidate. That they have attended lectures, &c., on the following subjects, at established schools of eminence, by physicians or surgeons of the recognised Colleges of Physicians or Surgeons in the United Kingdom, for periods not less than here understated, observing, however, that such lectures will not be admitted if the teacher shall lecture on more than one branch of science, or if the lectures on anatomy, surgery, and medicine be not attended during three distinct winter sessions of six months each:—

Anatomy (or general anatomy, twelve months; and comparative anatomy, six months), eighteen months. Surgery (or general surgery, twelve months; and military surgery, six months), eighteen months. Theory of medicine, six months. Practice of medicine, twelve months. If the lectures on the theory and practice of medicine are given in conjunction, then the period required is eighteen months (six months' lectures on pathology, if given at a university where there may be a professorship on that branch of science, will be admitted in lieu of six months' lectures on the practice of medicine). Clinical lectures, at a hospital as above (or the practice of medicine, six months; and the practice of surgery, six months,) twelve months. Chemistry (or lectures on chemistry, three months; and practical chemistry, three months,) six months. Materia medica, six months. Midwifery (accompanied by certificates stating the number of midwifery cases personally attended,) six months. Botany (or general botany, three months,) six months.

In addition to the tickets for the lectures, certificates must be produced from the Professors, &c., by whom the lectures were given, stating the periods (in months) *actually* attended by the candidates. The time also of actual attendance at a hospital or infirmary must be certified, and the tickets, as well as certificates of attendance, age, moral character, &c., must be produced by the candidate immediately on his being desired to appear for examination.

Although the above are the only qualifications which are absolutely required in candidates for the appointment of assistant-surgeon, a favourable consideration will be given to the cases of those who have obtained the degree of M.D. at either of the Universities of Oxford, Cambridge, Edinburgh, Dublin, Glasgow, or London, or who, by possessing a knowledge of the diseases of the eye, and of any branch of science connected with the profession, such as medical jurisprudence, natural history, natural philosophy, &c., appear to be more peculiarly eligible for admission into the service, observing, however, that lectures on these, or any other subjects, cannot be admitted as compensating for any deficiency in those required by the regulations.

By the rules of the service, no assistant-surgeon can be promoted to the rank of surgeon until he shall have served three years in the former capacity, one year of which must be in a ship actually employed at sea; and it is resolved, that not any diploma or certificate of examination from either of the aforesaid Royal Colleges shall be admitted toward the qualification for surgeon, unless the diploma or certificate shall be obtained on an examination passed after a period of not less than three years' actual service, observing, that no one can be admitted to an examination for surgeon, unless he be a member of one of the above-named Royal Colleges; and whenever Assistant-Surgeons, (already in the service (whose professional education may not be in accordance with the above), obtain leave to study previously to their passing for surgeon, they will be required, on their examination, to produce testimonials of their having availed themselves of the period of leave to complete their education, agreeably to these regulations.

It is also to be observed, that candidates who may be admitted into the naval medical service must serve in whatever ship, &c., they may be appointed to, and that, in the event of their being unable to do so from sea-sickness, their names cannot be continued on the naval medical list, nor can they, of course, be allowed half-pay.

ORDNANCE MEDICAL DEPARTMENT.
68, PALL-MALL.

Regulations for the Admission of Candidates.—Provisional List.—Medical students who have completed their twentieth year, who have been well instructed in the Latin and Greek languages, the elements of mathematics and natural philosophy, and who can produce satisfactory proofs of being of good moral character, and diligent in the study of their profession and the sciences connected with it, may be entered in the provisional list of gentlemen desirous to be admitted candidates for employment in the Ordnance Medical Department. A knowledge also of modern languages, though not indispensable at the time of provisional reception, is highly desirable, and will be duly appreciated.

Candidates.—No applicant is to be received on the list of candidates before he is twenty-two, or retained on it after he is twenty-five years of age. The age of every individual must be verified by a certificate of his baptism, if it can be procured. He must be also unmarried, and in the full enjoyment of health, both bodily and mental.

Qualifications.—Every candidate must produce a diploma from one of the Colleges of Surgeons of London, Edinburgh, or Dublin; and a certificate of qualification from the Society of Apothecaries in London. He must also bring proof of having diligently gone through the following branches of professional education, nearly all of which are required to enable him to take out the above-mentioned diploma and certificate—viz., of having served an apprenticeship of five years to a surgeon and apothecary, if educated in England; but if not, qualification in the practice of medicine and pharmacy equivalent thereto; of having attended the practice of surgery in a recognized hospital or hospitals, where clinical instruction is constantly given, for three years, three months being allowed for a vacation in each year; of having attended the under-mentioned lectures, &c.:—

Anatomical lectures. Ditto—demonstrations. Ditto—dissections	Three anatomical seasons or sessions.
Morbid Anatomy and Pathology	One course.
Lectures on the principles and practice of surgery, delivered in two distinct periods or sessions	Two courses, each comprising seventy lectures, or one course of surgery, and one of military surgery.
Natural history, or comparative anatomy	One course.
Chemistry	One course of a hundred lectures.
Botany	One course.
Materia medica and therapeutics	One course of a hundred lectures.
Lectures on the principles and practice of medicine	Two courses, each 100 lectures; second and third winters.

Medical practice, with clinical lectures, eighteen months, commencing the second session, viz., twelve months in a recognised hospital, and the remaining six months either in a recognised hospital or a dispensary.

Medical jurisprudence, with toxicology	One course of fifty lectures.
Midwifery	Two courses, each of 30 lectures, second and third sessions.
Practical midwifery (not less than thirty cases)	After the conclusion of the first course of midwifery lectures, a certificate of having passed the usual examination is to be produced.
Diseases of the eye — With attendance on patients of that class.	One course.

He must produce a diploma from either of the Colleges in London, Edinburgh, or Dublin, and, if not a graduated M.D. of Scotland or Ireland, after having actually passed an examination in the University where he has obtained his degree, a cer-

tificate of qualification also from the Society of Apothecaries in London. It is likewise expected that candidates shall have attended establishments for the cure of diseases of the ear and skin, and for the treatment of patients affected with mental derangement. Certificates will not be received on more than two branches of science from one and the same lecturer; but anatomy and physiology, demonstrations and dissections, Materia Medica and botany, will be respectively considered one branch of science. In the certificates of attendance on hospital practice, and on lectures, the dates of commencement and termination are to be inserted in words at full length. The moral conduct and character of each individual must be certified by the gentlemen to whose care his education was confided; and also by a clergyman, who, if practicable, should be the incumbent or officiating minister of the parish in which the applicant usually resides. The documents above detailed are to be inspected by a Board, to consist of not less than five medical officers, after which they are to examine the candidate as to his professional acquirements. If his education has been chiefly medical, the examination will be principally in practical surgery; but if surgical, in the theory and practice of physic, including cluding pharmacy. The full qualification being required on admission, a second examination is deemed unnecessary.

EAST INDIA COMPANY'S SERVICE.

Regulations for the admission of medical gentlemen into the East India Company's Service as assistant-surgeons for India.

Age.—The assistant-surgeon must not be under twenty-two years, in proof of which he must produce an extract from the register of the parish in which he was born.

Qualifications in Surgery.—The assistant-surgeon, upon receiving a nomination, will be furnished with a letter to the Court of Examiners of the Royal College of Surgeons, to be examined in surgery, and their certificate will be deemed a satisfactory testimonial of his qualification; but should the assistant-surgeon be previously in possession of a diploma from the Royal College of Surgeons of London, or of the College of Surgeons of Dublin or Edinburgh, or of the College and University of Glasgow, or of the Faculty of Physicians and Surgeons of Glasgow, either of them will be deemed satisfactory as to his knowledge of surgery, without any further examination. He is also required to produce a certificate from the cupper of a public hospital in London, of having acquired and being capable of practising with proper dexterity the art of cupping.

Qualifications in Physic.—The Assistant-Surgeon will also be required to pass an examination by the Company's examining physician in the practice of physic, and to produce satisfactory proof of his having attended at least two courses of lectures on the practice of physic; and, above all, that he should produce a certificate of having attended diligently the practice of the physicians at some general hospital in London for six months.

The Assistant-Surgeon is also required, as a condition to his appointment, to subscribe to the Military or Medical and Medical Retiring Fund at his respective presidency, and also to the Military Orphan Society, if appointed to Bengal.

The Assistant-Surgeon is required, by a resolution of Court of the 21st of May, 1828, to apply at the office for cadets and Assistant-Surgeons for his orders for embarkation, and actually proceed under such orders within three months from the date of being passed and sworn before the Committee for passing military appointments; he will then be furnished with an order to obtain the certificate of his appointment, signed by the Secretary, for which he will pay a fee of 5*l.* in the Secretary's Office.

Assistant-Surgeons who shall fail to apply at the cadet department for their orders within three months from the date of their being passed and sworn before the Committee, or shall not actually proceed under such orders, are considered to have forfeited their appointments, unless special circumstances justify the Court's departure from this regulation.

Cholera at Boulogne-sur-Mer.—We are informed that cholera raged at Boulogne with greater violence, taking the population into account, than in any town in France. Notwithstanding the Mayor's late assertion that it was confined solely to the lower classes, we have reason to know that many English visiters in good circumstances fell victims to the disease. Mr. Meridew, the much respected English librarian, died of cholera after five hours' illness; also Mrs. Hussey, the proprietor of the British Hotel, and several inmates of the house, which was immediately closed, and has since passed into other hands. It has often been boasted that neither plague nor pestilence could enter the Hauteville, so healthily situated was that part of Boulogne; and certainly, in 1832, it escaped the invasion of cholera. Last week, however, the charm was broken, for four persons were lying dead of cholera in a house in the Rue de Balance, near the Calais gate. Madame Chevaux-Sier, the wife of the ex mayor, has also died from cholera after a very brief illness; but then her death was attributed to having eaten largely of melon and cucumber. It is remarkable, how interest affects opinion, and how people who have houses to let, and live upon visiters, refuse to believe, or rather deny, that cholera is rife among them, and attribute every death to any but the right cause. The number of deaths in Boulogne from apoplexy and disease of the heart, make those diseases much more common than most men wot of. The indifference, too, of the authorities to the simplest sanitary measures, is, to say the least of it, singular. The river Liane, when full, and the flood-gates closed, forms one of the chief ornaments of the town; but when the water is let out, and its muddy bed exposed to the action of the sun during a long summer day, what ought to be both ornamental and useful is converted into a fertile source of miasma, ague, &c. Still, during the past season, the water has been oftener out than in, and without any other cause being assigned than that of the trouble of letting it in and out; for, unfortunately, the works going on along its banks have been suspended since July for want of funds to carry them on.

We have to repeat our request that gentlemen, when they favour us with communications, will have the candour to inform us, if, at the same time, they have forwarded copies for publication to any of our Contemporaries. Every Editor ought to be allowed to exercise his own judgment as to a Communication being of sufficient value or importance to warrant its appearance simultaneously in more than one Journal. For our part, we claim the right to use our editorial discretion as to the admission of such papers into this Journal; and, the columns of the *Medical Times* will be closed against those who may offend in this matter. Moreover, we would remind whoever it may concern, that the act of sending the same paper to contemporary Journals has a very quackish, and therefore unprofessional appearance; it seems as if the writer sought more to circulate his own name, than to advance science; and, when such a motive influences an author, then, in our opinion, an advertising column of the daily press is the most appropriate medium for his purpose.

Complaints having reached us of the irregular delivery of the MEDICAL TIMES *in the country by the Booksellers and Newsmen, we state, for the information of our readers, that this Journal is always published early on Friday afternoon, so that it may reach the Provinces by post on Saturday morning.*

Correspondents are requested to address their Communications to "The Editor of the MEDICAL TIMES *147, Strand."*

TO SUBSCRIBERS.

New Subscribers will oblige by forwarding their Names direct to the Office, 147, Strand, or to the News Agents or Booksellers. All Post office Orders should be made payable to the Publishers, WM. S. ORR AND CO.

THE MEDICAL TIMES.

SATURDAY, SEPTEMBER 29, 1849.

THE approach of another Session reminds us of our annual duty; and glad indeed should we be, if any remarks of ours should incite those whom we address to a consideration of theirs.

The occasion suggests many thoughts more or less applicable to the existing state of society, to the demands of the times, and to the altered condition of the Medical Profession—a condition which imposes upon the student severe mental exertion, and an energy and concentration of power, neither exacted nor deemed necessary in years past. Those who have to live by the exercise of their talents, will have in future to contend against no ordinary difficulties. To lessen these, or smooth the path to independence, they must justly appreciate the value of the present moments. To them they are indeed golden. We are not unmindful of the natural feelings of youth—of youth let loose from imaginary thraldom, and thrown inexperienced upon the great Metropolis, with high hopes, with a limited and vague knowledge of mankind, with restless desires, and, too often, with the means of gratifying them. Alas, for the consequences which often follow! Of all these we are fully sensible. It is the knowledge of them which dictates our remarks.

In our early days the career of the student was, for the most part, one of gross dissipation. It never seemed to be contemplated, that the studies entered upon could possibly have any other object than simply the attainment of the privilege to practise. As for any anxiety, industry, or enterprise, to acquire distinction by the variety, accuracy, or extent of professional information, it was scarcely known; nay, he who manifested a disposition to make the most of his opportunities, was subject to no trifling impediments from the generally reckless conduct of his associates. Amusements and sensual indulgences were the order of the day. The theatre, the opera, the fives-court, gambling, and licentiousness, were the places and the mode in which they sacrificed their health and money, and squandered that irretrievable element—Time. Towards the close of the Session, as the grand ordeal approached, by which their *passing*, but not practical efficiency, was to be tested, then came the struggle to get up the necessary knowledge. Of the expedients employed for the purpose we have a lively recollection. Short and ready methods of impressing facts upon the mind, without the slightest regard to the principles connecting them, either in a physiological or pathological point of view, were the means almost universally employed. Then came the trembling and momentous occasion. An assumed diffidence, agitation, and embarrassment, were considerately imagined, by the courteous and indulgent Examiners, to be in keeping with the peculiar position of the student; and this allowed both parties time,—the one gradually to break the ice, and the other to think before he replied. An approximation to truth, in the answers given, was, in those days, no mean merit, and added no little to the claims of the aspirant. If rejected, the examination was an unfair one, and of course the candidate had been most harshly and unjustly treated. There was never any difficulty in finding reasons to explain the result, without dreaming of a want of knowledge. If, however, successful, he returned to his friends, with his high honours blushing thick upon him, and naturally excited their sympathies by the consideration of his uninterrupted and severe exertions. He had got his passport to practise, and that which was supposed to be a guarantee of his ability to exercise his art with marvellous advantage, both to his patients and to himself.

We have no desire to trace him further; nevertheless an analysis of the subsequent steps in his career might be rich in practical instruction. He is at present vividly before us, after the lapse of many years. He soon lost the flashing exterior, the taste and dandyism of a town life. His old habits, however, clung to him. The glass and the social circle had still their attractions, and, the abundance of time at his command, allowed him most freely to indulge in them. The misery of living alone suggested a ready cure, and the results of it were strong and additional demands upon his energies. Fortunate, indeed, if he responded to them by aroused and well directed labours.

But now all these things are changed; and we would have the student of the present day to be sensible of the vast revolution which has taken place in the requirements and condition of society. Competition has not only become an awakening consideration,—and hence the necessity of unabated application in the acquisition of knowledge, but the public at large have become much better judges than formerly of the talents of those whom they employ. The peculiar degree or authority to practise has lost much of its *prestige* and influence. It is the Man—whether of Cambridge or of Oxford; of Edinburgh, London, or of Dublin; Glasgow, St. Andrews, or Aberdeen,—and his recognised and unquestionable talents, that can alone make way. For him, there is always an arena open to his exertions; and, though even he will have trials to meet and difficulties to overcome, he will ultimately surmount them, and dignify the Profession to which he belongs. That even he will have to wait his time is no subject of regret. The probationary period is the most valuable of his life. It permits him gradually to extend his knowledge, and to elaborate and classify his experience; to look at Nature, not through books or systems, but through that medium which alone presents clear, practical truths,—the actual examination of disease. We are disposed to think that men usually get into practice as soon as they are efficiently prepared for its duties.

Though we are far from being inclined to underrate the value of distinctions attained in Medical Schools, as a measure of the talents of those who obtain them, they are, however, no great indications of the fitness of the individuals to enter with advantage on the onerous and embarrassing responsibilities of the Profession. They are the flower of the plant,—and, from its luxuriance, full of high promise,—but the fruit comes at a later season. The sun and the breeze have to play their part before it can be appropriated to any profitable purposes. So it is with the talents of the young and enterprising. We would also further remark, that the extraordinary efforts made to secure these distinctions are not without their drawbacks. They too frequently concentrate the attention to some particular pursuit, to the exclusion of that general survey of the Medical art, which is indispensably necessary to its beneficial exercise. These very clever men are frequently very ignorant at the bed-side of the patient. They have all sorts of knowledge,—save that which a just appreciation of disease requires. Their flourish of principles, and display of varied scientific lore, are often accompanied with a species of contempt of that drudgery and patient toiling after the minutiæ of details, without a familiar acquaintance with which, principles are of little value.

If the attainment of these distinctions or honours narrow or limit the attention to a comparatively small field of inquiry, it is unwise in the student to make the sacrifice. His time can be much more usefully employed in the laboratory, the dissecting-rooms, or the hospital wards. The last should engross his untiring attention. It is here that he has an opportunity of studying disease on a most extensive scale; it is here that he will cull precepts, and enjoy the inestimable advantage of observing the re-

sults of the exercise of his art in the hands of men, whose talents and industry have obtained for them so commanding a position.

Let him not forget the high objects of his Profession, nor the importance of knowledge. The season of study is short, the occasions for improvement many, and on the mode in which he uses them, depend his success and respectability in life. If he flatter himself that success is a species of lottery—a game of chance, and hence a matter of indifference how he prepares himself for the struggle, he labours under a serious error and gross delusion. If he will endeavour to merit the countenance and support of the public, though he must calculate on difficulties, (for these are inherent in the existing state of society,) he will be astonished at the facility with which they may be overcome. *A wise man by his conduct creates good luck. It springs naturally beneath his footsteps. It comes to those who are prepared to appreciate it.*

Good fortune in every pursuit of life is not so much a matter of accident as is generally imagined. A man may receive an unexpected legacy, or may chance to light upon a mine of wealth; but these are the exceptions to the rule. "Conduct is fate." Success depends upon some mental quality; and it does not necessarily follow that it shall be distinguished talent or vast acquirements. It may be persevering industry, and a sedulous waiting for favourable occasions. The mental elements which these imply are essential to success. Were we intimately acquainted with the history of those who start out from among the mass, whether in trade or in any of the walks of the learned Professions, it would be found, that he who acquires wealth or influence—who takes the lead of his neighbours—has brought into action some mental quality which they either do not possess or have not exercised.

It is not unusual to regard with astonishment and envy the supposed good luck of others. We survey their mansion, establishment, or their command of the luxuries of life, as if these had been called into existence by a species of magic, or legerdemain, or spell of potent agency. If we descended a little into particulars—took the pains to analyse the steps by which they had risen—we should discover that very ordinary means had been employed, though not, perhaps, in a common way.

We are anxious to impress these truths upon the minds of the rising generation of practitioners. We would not mislead them, by picturing a smooth and easy path, stretching wide and boundless before them. At the best, it will be a rugged one: beset with difficulties and disheartening influences. But let them take courage, and view these as means necessary to the free development of their energies and their talents. If in doubt as to the best mode of attaining their object, let them studiously examine the circumstances which have promoted the success of those around them. There is seldom any mystery about the source of success. It will probably be traced to the superior abilities, skill, or acquirements of the individuals, the nice honour or propriety of their conduct, or it may possibly arise from untiring and unwearying industry in association with comparatively very humble mental powers. The contemplation of these qualities in actual operation will furnish an inexhaustible lesson of practical wisdom.

We remember the high hopes—the buoyancy of spirits—the unreasonable anticipations, unfruitful calculations, and unfounded data, of our own early career. Time, however, invariably corrects these false estimates. We do not wish to lessen the just value of these qualities, for they have an important use. Without them, it would be impossible to carry on, from day to day, the great struggle of life. Our object is to give them a legitimate direction, and, if possible, to impart to them the sober hue of experience.

The cessation of the labours of the student is too frequently the cessation of study. Books are consulted, but little read. The privilege to practise should not be regarded as an end, but as a means, and as furnishing incitements to further mental exertion. The information which has been forced upon the mind has necessarily brought under observation various departments of knowledge; and some of these, according to the taste or talents of the individual, should claim his especial attention. It should be his aim and ambition to endeavour to dignify the Profession to which he belongs, by the extent or respectability of his attainments. In proportion to the energies so aroused and directed, he brings into the field of competition one of the elements essential to success. It has, however, other relations, far more important to himself. What is existence worth without refined resources of enjoyment? These can spring only from the cultivation of the mind; and he who neglects the opportunity which the leisure of early professional life liberally presents for the acquisition of knowledge, will never cease to regret the misapplication of his time and talents. No exertion will afterwards recover the lost ground. It is gone for ever.

The occasion calls for one other remark. There is a circumstance to which we have not yet alluded, which materially leads to success; viz., a devoted attention to the necessities of the poor. They afford a rich field for the investigation of disease, and seldom fail to lead to a large and lucrative practice. The needy and the wretched are important links in the social circle, and, by a law of our nature, excite an interest and awaken warm sympathies in others more favourably situated. These are to be reached through the miserable hovels and apparently unnoticed sufferings of the poor, and the latter have a claim on the resources of our art, independently of all other circumstances; they have, however, a value, as a means to professional advancement, which is rarely fully estimated by the young practitioner. They are the steps by which alone we can rapidly progress, and he who neglects them, though he may ultimately succeed, it will be with far greater difficulty. We question, moreover, whether the foundation he lays is ever so sound or secure as when it results from the wide and grateful impression left upon the minds of the humbler classes of society.

Let these observations fall as fruitful seeds on the minds of those who are now entering on the severe studies of the Profession. They are prompted by one feeling only:—The desire to guide their efforts and promote their interests, and on the mode in which they discharge their duties will depend their future success and respectability in life.

And now one word in reference to ourselves. We have our duties as public Journalists, and we have endeavoured, to the best of our ability, to discharge them efficiently. An honesty of purpose, a regard to the just claims of all parties, and a sincere desire to promote the true interests of the Profession, are the motives by which we are actuated. Whatever objections may in former years have been alleged against the management of the *Medical Times*, they cannot in any degree be urged since it has fallen into the hands of the present Proprietors. To elevate its character, and enlarge its usefulness, has been their constant study. The greatly increased circulation of the Journal, and the distinguished names which adorn its columns, are acknowledgments, on the part of the Profession, that their exertions have been justly appreciated. The same anxiety, the same liberal and independent line of conduct, swerving from the performance of no duty, will equally distinguish their efforts for the future.

DR. BRITTAN'S CHOLERA VIEWS.

We understand that some interesting, and, possibly, very important microscopic observations on the discharges from the stomach and bowels in cases of Cholera, have been made by Dr. Brittan, of Bristol, a very able and dexterous anatomist. These observations have not yet been made public, but, as a contemporary has referred to them, we see no harm in laying before our readers such particulars as have reached us. When Dr. Brittan has made known his researches, we shall more profitably determine as to their value.

It appears, then, that Dr. Brittan has discovered in the flocculent sediment which exists in the matter vomited and voided per anum in cases of Cholera, (and which has been variously considered to be mucus, fibrine, or another protein compound in a peculiar and as yet undetermined state,) certain organic corpuscles, which both to him and to other observers well versed in such inquiries, appear to be fungi. In their most developed condition these bodies are of some size, that is, are considerably larger than blood corpuscles. They have a well-defined transparent double outline, which occasionally becomes opaque and thickened. The centre is occupied by granular matter or by cells, and has somewhat of a yellowish or brownish hue. The smallest of these bodies are much more minute, and require the highest powers (such as Ross's or Powell's 12th) before they can be satisfactorily made out. They then appear as minute cells, with a clear double outline, and bear a very strong resemblance to the sporidia of fungi. Both kind of cells appear to be spherical, or but slightly flattened, and the transition from the one into the other can be traced with a little care. These bodies are not to be confounded with the granular cells which Dr. Brittan also finds in great numbers.

Did the observation stop here, the discovery of fungi different from the common torulæ, which often form rapidly in cholera stools, and which have been figured and described by Boehm and others, would, no doubt, if confirmed, be highly important. But Dr. Briftan has proceeded further. By causing the air of rooms and districts in which Cholera is prevailing, to pass through a glass tube surrounded by a freezing mixture, he has condensed the atmospheric watery vapour. In this vapour he finds under the microscope, minute spherical bodies, corresponding as far as the eye can determine, most completely with the smallest kinds of the presumed fungous cells, which can be noted in the Cholera dejections. We understand that observers of the highest eminence in this department of Histology, have expressed a decided opinion as to the identity of these bodies.

Such are the very few particulars which have reached us during the last few days in reference to this subject. We have brought them thus prominently forward, in order that, before the Epidemic subsides, they may be submitted to scrutiny by others. The slightest hint which may lead us to a better understanding of this fatal disease ought not to be neglected; and it is an imperative duty on us all to follow up, and submit to the touchstone of observation, any clue which may seem likely to guide us in our search.

At present it would be almost impossible to estimate the exact value of Dr. Brittan's observations. We have first to determine what these bodies are; since, of course, it is by no means certain that they are fungi. But, supposing they *are* fungi, they may merely be products; low cellular forms developed rapidly in the favourable matrix of the cholera stool, just as the little vibriones are, which sometimes can be seen under the microscope moving in shoals in a dejection which has only the moment before been passed from the body. Perhaps the spores of these fungi may exist at all times in impure and contaminated air, and may merely find in the cholera discharges their appropriate blastema. We foresee the greatest difficulty in deciding upon some of these points, and, assuredly, the only accurate method will be, to make at once an inquiry as extended as possible into all the questions connected with the subject. Apart from any investigations into the nature and structure of these bodies, the following points strike us as being preliminary inquiries which must be settled before we can venture even to *surmise* that these fungi are the cause of cholera—1. Are they present in all cholera stools? 2. Are they present in all cholera localities? 3. Are they absent from the discharges in all other diseases? 4. Are they absent in all localities where there is no cholera? If these questions were all answered in the affirmative, we should then have arrived at this point: the presence of a cholera fungus would prove to us the existence of certain causes which produce cholera, in the same way as the presence of the yeast plant proves the action of the causes which produce fermentation. But as the yeast plant is merely an index of the extent of the fermentation, and a token of that complex interchange of elements which, arising as far as we know from deeper forces, produces that torula as one of its necessary results, so also these fungi may be merely the material evidences of those more recondite and subtle forces, which call these elementary germs into life, at the moment while they strike the more complex organisms with death.

We allude to these difficulties for the purpose of calling attention at once to them, and with the hope that some thorough investigation will be set on foot. We do not in the least underrate the importance of Dr. Brittan's researches: we are expressing probably opinions similar to those he himself entertains. Nor do we wish to overlook the fact, that, singularly enough, some observers, as Cowdell and Mitchell, have concluded, from analogical evidence, that the active cause of cholera might be a species of fungus. But we are merely desirous of preventing any hasty conclusions, which, if not based on perfect evidence, cannot but be detrimental to the progress of truth.

Since the above Article was in type, the undigested opinions we anticipated have already commenced to be circulated. Already men, who should be wise, are jumping at conclusions which it is *impossible* they can at present *prove* by evidence. We are truly grieved to find a man of the reputation of Dr. Budd, of Bristol, publishing such a letter as appeared in the Daily *Times* a day or two ago. Whatever may be the truth of the opinions contained in this letter, they cannot at present be otherwise than mere guesses; and if true, can be no more than lucky hits. Whether true or not, what can we think of the logic and philosophy of a man who has ventured to settle the whole pathology of Cholera on the basis of a few imperfect observations? But we shall return to this subject next week, and then further allude to some conclusions in Dr. Budd's letter, which appear to be even irreconcileable with each

PROGRESS OF MEDICAL SCIENCE.

IRELAND.

(From our Dublin Correspondent.)

MEDICAL SCHOOLS AND HOSPITALS OF DUBLIN.

Six medical and surgical schools will, during the session of 1849-50, be opened in the Irish Metropolis. Three of these are under the patronage of corporate bodies, by whom their Professors are elected; namely, the School of Physic, at Trinity College; the School of Surgery, in York-street; and the School of the Apothecaries' Hall, built on the site of the old Dublin theatre, in Cecilia-street, opposite Crow-street. The other three are what are called private schools, being got up exclusively at the expense of the lecturers, who, however, must satisfy the various medical corporations as to education and competency, in order to have their certificates recognised. This recognition has hitherto been too frequently a matter of form; but the Irish College of Surgeons has, of late years, very properly exercised a strict *surveillance* over the capabilities and pretensions of those who assume the responsible functions of professional teachers. Two of these private schools are situate in Peter's-street, and the third in North Brunswick-street. The Park-street School of Medicine, so long distinguished, both on account of the eminent men who have lectured within its walls, and the excellence of its Pathological Museum, will be, in future, discontinued. Of the great men who formerly drew attention to it, some, like the lamented Houston, have paid Nature's last debt; others, such as Graves, Marsh, Cusack, &c., have ceased to lecture; and the remainder, among whom we may mention the names of Stokes, Apjohn, Harte, Jacob, and Wilde, are scattered among other Institutions. The Museum, we are given to understand, is destined for the Queen's College at Belfast.

As there are so many existing Schools of Medicine, it may be imagined that there is a good deal of competition between them in order to attract pupils. The branches lectured on will, in future, be nearly the same in all, inasmuch as a Professor of Surgery is about to be added to the School of Physic, in which Institution this department was formerly conjoined with Anatomy. There is, indeed, a distinct course of lectures delivered at the School of Physic, on the Institutes of Medicine. In the other schools, *physiology* is conjoined with anatomy, and *pathology* with the practice of medicine. This appears to be the most reasonable arrangement; but, as some of the Universities still require separate certificates on the Institutes of Medicine, it is for the convenience of students in Dublin to have the opportunity of taking out such certificates in that city. The other subjects, upon which courses of lectures will be given in the various schools, are—1st. Anatomy and Physiology; 2nd. Surgery; 3rd. Medicine; 4th. Chemistry; 5th. Materia Medica; 6th. Medical Jurisprudence; 7th. Midwifery; 8th. Botany. The fees payable for attendance on these several courses are the same in all the schools, with the exception of the School of Physic. These fees are 3*l*. 3s. for each course, except Anatomy and Surgery, which are 2*l*. 2s. each. All the courses at the School of Physic are 4*l*. 4s. each. The only compensating advantage for these larger fees at the School of Physic is, that the certificates issued from it are recognized by the Universities of Edinburgh, Cambridge, Oxford, and Dublin; a privilege not conceded to the other schools of Dublin; but this advantage is more than neutralized by the non-recognition of school of physic certificates by the Dublin College of Surgeons. These mutual exclusions, the remnants of barbarism, inflict considerable inconveniences upon students, particularly those who intend to practise in Ireland, inasmuch as those who have received their education in an extra-academical school are forced to take out their medical degrees at the London University, Glasgow, St. Andrews, or Aberdeen; while those, on the contrary, who have studied within the walls of the University are compelled to go to London or Edinburgh, if they wish to take out a license to practise surgery.

We have already said that considerable competition exists between the various medical schools; but as the fees are the same in all, this competition is forced to confine itself for the most part to promises of extraordinary advantages, either in assistance to the pupils' studies, or the offer of valuable premiums. We strongly advise students to beware of either of these lures. Dissecting-rooms, illumined by numerous gas-lights, may attract moths who are fond of the glare, and sometimes singe their wings by indulging in this partiality; but they are of very little real use to the student who wishes to learn anatomy. Catechetical examinations, unremitting services of demonstrators, all these are to be regarded as suspicious baits, it may be, intended to divert the attention from important deficiences, such as the want of proper museums, or the existence of unwholesome dissecting rooms, or confined and inconvenient laboratories. And with respect to premiums, we have seldom known a prizeman who was a well-informed physician or surgeon. We do not now allude to premiums for clinical attendance, or for proficiency in any branch of practice, such as the use of the stethoscope, or the art of bandaging; but the prizes given in Medical Schools, we believe to be more frequently gained by the clever tactician, who can detect the pet subjects and peculiarities of the lecturer, than by the really honest-minded and industrious student. Besides, the young man who wishes to acquire an equally extended and practically useful knowledge of the different branches of his profession, cannot be expected to find time to devote himself to any particular department, so as to entitle him to compete for a premium; yet it

must be mortifying, both to himself and his friends to find himself apparently outshone by a fellow-townsman, it may be, who, although perhaps far inferior in general and practical information, is enabled, by a little worldly wisdom and specially applied industry, to parade a prize as the signal of his desert before their mutual acquaintances. Besides the forms of competition alluded to, others less creditable are occasionally resorted to, such as the spreading of *on dits* concerning special recognitions, or other peculiar advantages attached to particular schools. We trust we shall not hear of any trick of this nature being practised during the coming session. On the whole, we recommend the student to be guided in the selection of the school which he would enter, by the characters of the teachers, and by a personal examination of the ways and means of instruction offered to him.

There are seven joint Medical and Surgical, and one purely Medical Hospital open to students in Dublin. The latter, or Sir Patrick Dun's Hospital, is chiefly attended by gentlemen intending to graduate in Medicine at the University. The Meath Hospital—an Institution which has acquired a more than European reputation—contains about 120 beds; a proof that, for the purpose of successful clinical teaching, ability and zeal on the part of the instructors is of greater importance than a wilderness of crowded wards. Dr. Steevens' Hospital contains 200 patients, and is provided with distinct venereal wards. The Richmond, Hardwicke, and Whitworth Hospitals, although distinct buildings, and called by different names, may be regarded as different parts of the same Institution,—one department being for surgical diseases, another for fever, and a third for other medical diseases. This Institution contains 346 beds, and has acquired a deserved reputation from the untiring zeal and industry of the surgeons attached to it. Of the minor hospitals, St. Vincent's is particularly deserving of notice. This charity was established by the Sisters of Charity, an order of Roman Catholic nuns. The building—an enlargement of the noble mansion, formerly the town residence of the Earls of Meath—is situated in Stephen's-green, in a very central part of the city. It is strange to walk up the broad oak stairs, and enter the magnificent rooms and survey the richly stuccoed ceilings, and then reflect that you are within the wards of a hospital. Nothing can exceed the neatness and cleanliness of all the details, and the various arrangements conducive to the comfort and welfare of the patients are carried out with the most scrupulous exactness and regularity under the superintendence of the Sisters. We feel bound to state, that with the fullest opportunities of investigating the working of this establishment, into which patients are admitted without the slightest distinction of creed, we have never observed the slightest attempt at proselytism on the part of the *religeuse*, through whose philanthropy it has been called into existence. The hospital contains eighty beds for medical and surgical cases, and a ward especially devoted to the diseases of children. A very well attended Dispensary is attached to the Institution, which the Medical Officers attend by turns. That these gentlemen will avail themselves of the opportunities thus afforded them, the pages of the *Medical Times* sufficiently testify.

The other Medical and Surgical Hospitals in Dublin, open to Students, are Mercer's, the City of Dublin, and Jervis-street Infirmary; the latter, from its locality, is usually the recipient of cases of severe accident; on this account, especially, it is deserving the attention of the Student. The fees for Hospital attendance vary from twelve to eight guineas per annum.

There are five Lying-in Hospitals in Dublin. The Rotundo Lying-in Hospital is a truly noble building, an ornament to the city, and a lasting memorial of the philanthropy and genius of its founder, Bartholomew Mosse. Great Britain and Ireland may be well proud of the munificent charity displayed by so many of their children. The instances have not been few of men, labouring all their lives in trade and commerce, and devoting the ample fortunes which they had thus realised to the relief of their sick and indigent fellow-creatures. But the conduct of Bartholomew Mosse was unique; he was not a man of fortune,—on the contrary, his efforts in the cause of humanity kept him always in straitened circumstances. It was in the midst of pecuniary difficulties and personal privations, and surrounded by calumnious aspersions and injurious thoughts, that he unceasingly and energetically worked for the one darling object of his heart—the establishment, in his native city, of an asylum for poor women, in the hour of their bitter travail. For this he went for subscriptions from house to house; for this he petitioned and re-petitioned the Irish Parliament; for this he had recourse to every variety of amusement calculated to entrap human vanity and love of pleasure to the side of benevolence; and, although rebuffed, misinterpreted, or condemned by the code of a rigid pharisaism, he, at length, succeeded in establishing the first lying-in hospital in Europe. Honour to his manes. This Institution is governed by a master, elected for seven years. He is permitted to take two assistants, who pay a sum of about 300*l.* for three year's enjoyment of the advantages of the Institution. The assistants live in the house, and either they or the master are always in readiness to assist the student in difficult cases. The wards are visited by the master at a fixed hour every day; courses of lectures on midwifery are delivered every session in the Theatre; there is a special ward for the diseases of women. The fee is 12 guineas.

The minor Lying-in Hospitals depend chiefly for means of instruction on attendance upon the parturient poor at their own residences. The fees are 10*l.* 10s. for intern pupils, and 4*l.* 4s. for extern.

Besides the schools and hospitals which we have mentioned, Dublin presents other and considerable advantages to the medical student. There is a very numerously-attended dispensary for the diseases of children, in Pitt-street; attendance on which may be cured by a small fee, and where much instruction may be acquired. We would also wish particularly to draw attention to the Hospital and Dispensary for Diseases of the Eye and Ear, situated in Mark's-street, and which contains 14 beds, and an average attendance of upwards of 100 out-patients.

Lectures, free to the public, are delivered at the Dublin Royal Society, on natural philosophy, geology, and other subjects.

The meetings of the Pathological, Surgical, and Obstetrical Societies are open to students.

Besides the libraries attached to the College of Surgeons, and some of the hospitals and schools, there is also an excellent medical reading-room in Grafton-street, one of the most central parts of the city.

QUEEN'S COLLEGES IN IRELAND.

As the arrangements of the medical schools connected with these Institutions are not yet completed, and as it is not yet certain to what extent they may be recognised by the licensing bodies, we shall refrain from entering into details that must necessarily be imperfect. We may state, however, that some changes have already taken place in the Professorships. Dr. Carte has resigned the Chair of Anatomy at Belfast; Dr. Carlysle has been appointed in his stead; and Dr. Alcock, hitherto Professor of Anatomy to the Apothecaries' Hall, has been appointed to the College Cork. Dr. O'Meara has also resigned the Chair of Materia Medica in Belfast, and Dr. Stewart has been appointed instead.

A course of lectures on Military Surgery, as required by the Army, Navy, and Ordnance Medical Departments, is annually delivered during the winter Session, by Mr. Tufnell, Surgeon to the Military Prison.

THE CHOLERA AND DR. BRITTAN'S VIEWS.

[To the Editor of the Medical Times.]

SIR,—In this week's Number of the *Medical Gazette* there is an announcement of the discovery, by Dr. Brittan, of Bristol, "of certain peculiar bodies, hitherto undescribed, as a characteristic constituent of cholera evacuations," &c.

In confirmation of the discovery made by Dr Brittan—a discovery on which I cordially congratulate him, while it gratifies me exceedingly, as it appears to promise a demonstration of the views published by me, in my "Disquisition on the Fungous Origin of Cholera," I may be permitted to say, that, in concert with my friend Mr. Curme, of this town, some microscopic investigations have been made into the nature and appearances of the exudations of cholera patients; and that, although our opportunities have hitherto been very limited, they have yielded *positive* results sufficient to encourage a more extended series of examinations.

To avoid the appearance of plagiarism, I think it well, before seeing the publication of Dr. Brittan's observations, to state, that in the clammy sweat accompanying the last stage of collapse in cholera, we have observed minute organised bodies closely resembling other bodies admitted by naturalists and microscopists to have a *protophytic* organization.

I should not have published this immature account of our incomplete investigation; but, with the twofold object of corroborating (it may be) Dr. Brittan's statements, and of vindicating myself from the possible imputation of piracy in anything I may hereafter publish on the subject; and I am, Mr. Editor, yours very obediently,

CHARLES COWDELL,
Physician to the Dorset County Hospital.

Dorchester, Sept. 22, 1849.

[We readily, in the above case, depart from our rule of never *knowingly* inserting in our columns papers or letters that are to appear in contemporary journals. We wish all our correspondents possessed the candour of Dr. Cowdell, and stated, with the communication forwarded to us, that it had also been addressed elsewhere.—ED. *Med. Times.*]

DR. TURLEY ON SALINE TREATMENT OF CHOLERA.

[To the Editor of the Medical Times.]

SIR,—Mr. C. T., aged 47, of robust and rather plethoric frame, was in good health at ten o'clock in the morning. Immediately after this he was seized with pain and cramps in the stomach and bowels; these soon extended to the limbs, so that the knees were drawn up to the shoulders, and the nails were nearly driven into the palms of the hands; he vomited his breakfast, and everything given for relief returned. A relative, a chemist, gave him a draught with aromatic confection, and twenty-five drops of laudanum in mint water. This returned, and so did two others such, before I saw him at twelve o'clock. The bowels had been but little moved. I found him on his sofa in a state of great prostration—cold clammy skin, bluish cheeks and mouth, hands blue, shrivelled and purple nails, pulse about 40, and very feeble and intermittent. He was prostrated to a great degree, perfectly helpless, and complaining of pain at the præcordia. I gave him a teaspoonful of common salt, and half that quantity of carbonate of soda in a glass of potass water highly effervescent. This remained and afforded him immediate comfort. In about a quarter of an hour I gave him in the same vehicle one of the powders of Dr. Stevens. He expressed himself better, re-action commenced; no cramps since the first powder; the face appeared more natural. We got him to bed, using every means to keep the body warm, and he became com-
ulse fuller an
doses of the powders in the course of the day, and a little gruel when he wished it, was all he had. He became restless and peevish in the night, and got no sleep. He was sleepless for three nights. Some mild aperient, after a little blue pill, left him well in a few days.

Remarks.—The sudden occurrence of the choleraic blueness in this case is worthy of notice. The cramps and sickness left after the first dose of salines. Warmth and proper colour supervened on the second dose gradually. Cholera had been rife in Worcester, but had declined considerably before Mr. T. became ill.

I am, Sir, &c.,
E. A. TURLEY, M.D.

Worcester.

MEDICAL NEWS.

Apothecaries' Hall.—Names of gentlemen who passed their Examination in the science and practice of medicine, and received Certificates to practise, on Thursday, September 20th, 1849:—Thomas Costerton, Great Yarmouth, Norfolk; Samuel Montgomery Charles Alfred Anderson Smith; Robert Clarke, Farnworth.

Obituary.—On the 8th instant, at Wisbeach, John Rose Weatherhead, Esq., surgeon, deeply lamented by a large circle of fri nds.—On the 14th instant, at Newport, Salop, Robert Higgins, Esq., surgeon, aged 77, in which town he practised for upwards of half a century.

War Office, September 25.- 1st Regiment of Foot—Acting Assist.-Surg. George William Peake, to be Assist.-Surg., vice Barron, promoted on the Staff. 72nd Foot—Acting Assist.-Surg. Daniel John Doherty to be Assist.-Surg., vice Horniblow, appointed to the Staff. 91st Foot—Assist.-Surg. Francis Reid, M.D., from the Staff, to be Surg., vice Power, deceased. Hospital Staff—Assist.-Surg. Luke Barron, M.D., from the 1st Foot, to be Staff-Surg. of Second Class, vice Hardy, deceased. Assist.-Surg. George Horniblow, M D., from the 72nd Foot, to be Assist.-Surg. to the Forces, vice Reid, promoted in the 91st Foot.

University College.—It affords us infinite gratification to inform our readers that we shall be enabled, through the politeness of its Author, to lay before them a corrected copy of the able Professor of Medicines' Lecture Introductory to the commencement of the Winter Session at University College.

Dentist to Christ's Hospital.—The office of Dentist to Christ's Hospital, vacant by the death of Mr. Fox, has been filled by the appointment of Mr. Tracy, of St. Bartholomew's Hospital.

Derbyshire General Infirmary.—A special general meeting of the Governors of this excellent Institution was held yesterday, for the purpose of electing a surgeon, in the room of John Wright, Esq., resigned. The High Sheriff, Mr. Jedediah Strutt, then proposed, and Mr. Eaton Mousley seconded, the nomination of Mr. Henry Francis Gisborne, as a gentleman well qualified to fill the vacant office. The Rev. E. H. Abney proposed, and Francis Wright, Esq., of Osmaston Manor, seconded, the nomination of Mr. S. W. Fearn. William Leaper Newton, Esq., proposed, and F. Hurt, jun., Esq., seconded, the nomination of Mr. S. H. Evans. A ballot was then taken, the scrutineers being William Eaton Mousley, Esq., for Mr. Gisborne; Mr. Burroughs for Mr. S.W. Fearn; the Rev. R. M. Hope for Mr. S H. Evans. The ballot was closed at four o'clock, when the chairman announced the numbers as follows:—For Mr. Gisborne, 134; Mr. S. W. Fearn, 55; Mr. S. H. Evans, 37. The Chairman then declared Mr. Gisborne duly elected.

New Lunatic Asylum at Bristol.—The Commissioners in Lunacy have called upon the Secretary of State to put in force the clauses of an Act of Parliament, empowering him to order the erection of a new asylum for the pauper lunatics of Bristol. It is said that the cost of such an asylum as the Commissioners contemplate will not be less than 50,000*l*.

We are happy to say, that the cholera, in most of the Provincial towns, is on the decline.

Sanitary Condition of the City of London.—In the Report of Mr. Simon, the Medical Officer of Health, on Tuesday, to the Commissioners of Sewers, he submitted a schedule of complaints, 128 in number, made to him, on the preceding day, by various Medical Practitioners of the city. Many of the matters complained of were such as must exert a most destructive influence upon the health of the population, and the complainants stated, that they had frequently addressed the Court relative to the subject of these grievances. There were thirteen instances of overcrowding given, against which no remedy could be found without the assistance of the Board of Guardians. He cited two cases only:—No. 48, Halfmoon-street, a filthy, stinking, ill-ventilated pest-house, in which fourteen families were collected, and from which fever was never absent; No. 4, Hartshorn court, where, in the midst of cholera and diarrhœa, nine persons were inhabiting a single small and stinking room. Eighteen instances of extreme non-ventilation were given; and there again sanitary improvement must be considered unobtainable while the admission of light and air in quantities requisite for health would subject the unfortunate inhabitants to the grievance of a double window-tax. Upwards of sixty cases were cited in which, notwithstanding all the Court, and the police, and the assistant-inspectors had done, the odious conditions of houses, cesspools, privies, &c., remained without remedy—cases each of which would require to be accounted for by those who were responsible for the enforcement of their orders in the several localities complained of, and he again most earnestly advocated the importance of all the powers of the Act of Parliament being directed unflinchingly against those owners of property in the city who persisted in maintaining the most active causes of disease in the midst of a population which the Court had undertaken to make healthy. Many instances were given of gross neglect of duty upon the part of the scavengers, and two in particular were cited in which refusal had been made by the scavengers to fulfil the terms of their contract without a bribe. Gully-holes were complained of in three instances, and in one case it was stated that a Petition had been fruitlessly addressed to the Court by several inhabitants of the vicinity of Bow-lane. Other nuisances were complained of in fifteen instances. Seventeen complaints were made on the subject of defective water supply, and one of them extended to the whole district of Bishopsgate. That the supply was uncertain and insufficient; that there had been no water for a week, for three weeks; that water was only turned on for half an hour at a time, were statements which occurred under that head, and which required prompt attention. The information was supplied exclusively by members of the Medical Profession, who were employed in three several districts in the treatment of disease, and who considered the circumstances to be essential causes of sickness and death among their patients. The Report concluded by stating, that the list of districts complained of included those in which, during the last three months, the largest mortality had occurred from epidemic causes, and where, consequently, the vigilance of the inspectors and the police might have been most usefully employed.

The Cholera in Dublin.—There has not been since Saturday a single fatal case reported. It is not, however, to be inferred from this, that the pestilence has suddenly disappeared altogether, but there are symptoms which medical men are disposed to regard as favourable to the latter supposition, namely, the gradual re appearance of the ordinary maladies incidental to this particular season of the year, such as colds, rheumatisms, &c. It has been the subject of remark, that since the first outbreak of the cholera in Dublin all other diseases to which flesh is heir seemed to have vanished, leaving, as it were, a clear field for the ravages of the terrible enemy. A like phenomenon was observed in the year 1832.

The Cholera in Paris.—*The Gazette des Hôpitaux* announces the still further decrease of the cholera and diarrhœa even beyond what had been anticipated. On Thursday and Friday week the number of cases in the civil hospitals were only 16 from the former, and 17 the latter; while the deaths on Thursday were 13, and on Friday only 7. In private houses the deaths were, on Wednesday 21, and on Thursday 18.

Cholera in France.—It is stated, that, in certain parts of the department of the Haut-Rhin, the terror excited by the cholera was so great, that for several days no one would venture to approach a person affected with the malady, nor aid in carrying the dead to the burial-ground; and the prefect of the department was obliged to call to his assistance the attendants of the military hospitals to perform those offices. A curious case lately occurred at St. Maurice. A young man, nineteen years of age, was attacked with cholera at five o'clock in the morning of the 8th. From that hour until ten o'clock the following morning, he drank 44 litres of water, four litres of red wine, and two large cups of curdled milk. The same night he was completely out of danger, and recovered.

Cholera Inoculation.—A surgeon at Marseilles proposes to inoculate for cholera; we are not, however, informed of the method he proposes to pursue. He has applied to the Government for permission to experiment upon a prisoner condemned for life to the galleys, and whom he proposes shall be set at liberty if he survive the operation. We need scarcely remark upon the absurdity of the proposal.

Cholera and the Plague.—The present epidemic in London seems to have carried off, on an average 150 persons per day, that is to say, about 1 in 10,000 inhabitants. Far higher, however, was the mortality of the plague of 1664, the official returns giving a mortality, from the 22nd of August to the 26th of September, of 38,195! and of this number one-third died in one week.

Worthy of Imitation.—It is proposed in France that the names of the medical men and students who have fallen victims to their attendance upon cholera patients, should be inscribed upon a marble tablet and placed in the Musée Dupuytren.

Invalid Chair.—We wish our London readers would call at Messrs. Brown, Brothers, 117, Jermyn-street, and inspect a chair they have just patented, and admirably suited for an invalid, as well as for lounging. It is so constructed that it applies itself to any position of the body, and strongly supports the loins and hollow of the back. It is, moreover, very portable and very cheap.

MORTALITY TABLE,

(Metropolis.)

For the Week ending Saturday, Sept. 22, 1849.

Causes of Death.	Total.	Average of Five Summers.
All Causes	1981	1008
Specified Causes	1965	1005
Zymotic (or Epidemic, Endemic, and Contagious) Diseases	1291	302
Sporadic Diseases:		
Dropsy, Cancer and other Diseases of uncertain or variable seat	32	44
Tubercular Diseases	163	190

TO CORRESPONDENTS.

"Dr. James Arnott."—We had prepared a reply to Dr. James Arnott's complaint, that we do not see sufficient cause for believing in the value of his proposal to treat cholera by benumbing cold. It must, however, stand over until next week, even although he charges us with ungentlemanly and undignified conduct.

"Dr. Dickson."—We can well imagine the delight and self-glorification of the author of the "Fallacies of the Faculty" when he made the notable discovery that the opinions of the "Medical Times" had borrowed from him some of their tone and colouring. But, alas! there is nothing new under the sun; and when we offered the suggestion that epidemic diseases might depend upon electrical influences, we only repeated an old proposition, and one that had been made long before Dr. Dickson deserted the broad path of the Profession, and took to more devious ways. When we next write upon the "Philosophy of Epidemics" we may allude to Dr. Dickson and his letter. In the meantime, if he is really in earnest about publishing it in our advertising columns, we do not object, but he must address himself to the commercial department of the "Medical Times" on the subject.

"B. An Annual Subscriber."—The term is employed to designate a simple bowel complaint.

"Mr. F. C. Howard, Linton.—We fear our correspondent would have to bear the expense."

"J. D., M.D. Edin."—The License of the Apothecaries' Company will give a legal qualification to practise in England.

"Medicus Junius" will find all the information he needs on Medical Education in the present Number.

"B." is thanked for his communication.

"Mr. John Davis, Galway."—(1) No doubt the oil is taken up to a certain extent by the absorbents. (2) The effects are not so powerful as when administered internally. (3) The alteration of colour is probably due to the metallic oxides.

"R."—(1) The Work will be brought to a close in the present volume. (2) Mr. Churchill, Princes-street, Soho.

"A Subscriber."—No difficulty whatever, with good proofs that the person had prescribed and compounded medicines for a patient.

A Correspondent, who signs himself "A Member of the Sydenham Society," informs us, that Dr. Greenhill is now translating the lost books of Galen from an Arabic M.S., found two years ago in the Bodleian Library, and that ptyalism is often produced by prussic acid and the preparations of iodine.

Erratum in Dr. Arnott's letter on the "Remedial Action of Intense Cold, in the "Medical Times," September 15. In third paragraph, for "chin" read "skin."

Owing to press of matter we are compelled to omit several very valuable communications, and among others, those from Dr. Aldis, Dr. Richardson, Dr. Drury, A London Physician, &c.

ORIGINAL LECTURES.

ON THE

LOGICAL APPLICATIONS OF PHYSIOLOGY TO PATHOLOGY.

A LECTURE

INTRODUCTORY TO THE COURSE ON

THE PRINCIPLES AND PRACTICE OF MEDICINE.

Delivered by Professor WALSHE, M.D., at University College, London, October 1, 1849.

GENTLEMEN,—On the occasion of appearing before you for the first time, as your instructor in the Theory and Practice of Medicine, it would seem not only natural, but almost imperative, that I should explain to you the views which I entertain of the just and appropriate basis of that theory and that practice. It would, for several reasons, have been well, could I have entered fully into an explanation of the kind; and, forced as I am by limitation of time to relinquish the idea of even an attempt at a complete exposition of the subject, I will still endeavour, at least, to touch upon some fair share of its more prominent points. It will be thus practicable for me to give you, inferentially, an insight into the character of the evidence, and into the mode of using that evidence (especially when derived from certain collateral sciences) which I am disposed to believe essential to the solid establishment of the Science of Pathology, or General Doctrine of Disease.

§ II. Placed conspicuously before you are four Tablets, on which are inscribed the fundamental plans, by which, in the sequence adopted, the science of Pathology is, I conceive, to be *directly and immediately formed.*

I.

CASES OF DISEASE SUBMITTED TO

OBSERVATION,

LEAD TO THE ESTABLISHMENT OF

Individual Pathological Phenomena.

II.

INDIVIDUAL PATHOLOGICAL PHENOMENA

SUBMITTED TO

INTERPRETATION,

LEAD TO THE ESTABLISHMENT (PROVISIONALLY)

OF THE

Nexuses of those Phenomena.

III.

THESE PROVISIONALLY ESTABLISHED NEXUSES,

SUBMITTED TO

NUMERICAL COMPARISON,

ARE JUDGED, AND SO LEAD TO THE ESTABLISHMENT

OF THE

General Laws of Diseases.

IV.

THE GENERAL LAWS OF DISEASES SUBMITTED TO

CLASSIFICATION,

CONSTITUTE

The Science of Pathology.

Hence the intellectual processes by which the Science would be formed, are, successively, Observation, Interpretation, Numerical Comparison, and Classification. And, commencing with individual cases of disease, we should be gradually led to classified laws,—the substance and essence of the science of disease, and the highest generalizations at which human intelligences may legitimately grasp. I need, in truth, scarcely remind you, that in our Science, First Principles are utterly unattainable; for the counterpart of the gravitation of the Natural Philosopher, the Pathologist may sigh in vain.

Now, the prominent characteristic of the scheme for the foundation of Pathology, I here set forth and espouse, is its independence. It recognises facts of its own kind—not only kindred, but identical, in quality—as its sole basis. It makes no provision for the qualification of its laws by, much less for the formation of these laws out of, facts or generalizations belonging to other sciences, be the consanguinity of these sciences ever so close, and, *ex naturâ rerum*, direct. It holds Pathology to be a code of doctrines, founded upon distinct, proper, and special elements—elements whose ultimate adaptation to that code takes place utterly irrespective of *à priori* notions pressed forward by cognate branches of knowledge. It gives Pathology a place as purely self-dependent and distinct, in regard of the means of its *actual establishment as a science* (but of this only), as is held by chemistry, for example, in the sciences of matter. Or, more clearly to particularize, this scheme refuses by implication to recognize as the *true formative material* of the science of Pathology (that is, the sum of classified laws of diseased actions), inferences deducible, prior to experience, from current notions (whether possible, probable, likely, very likely, or certain), held concerning the natural texture and healthy actions of the frame. This scheme denies that physiology (vital, chemical, or physical) is the basis of Pathology, in the sense that acquaintance with the one secures by involution acquaintance with the other. This scheme denies that physiology is the basis of Pathology, in the sense that, given the recognized healthy life of an organ, the consequences of the derangements of that life can by any forms of reasoning, inductive, deductive, analogical, or other, be positively predicated prior to actual experience of their character and habitudes. It affirms, on the contrary, that from the Observation, Interpretation, Numerical Comparison, and Classification of those derangements themselves (collated, of course, with healthy conditions), are their nature and laws alone to be established.

But is not this scheme tainted with heterodoxy? To all seeming it must plead guilty to the charge; it does, in truth, clash with the doctrine *verbally accepted* as part of medical grammar, and repeated from lip to lip, as though constituting a fundamental judgment, against which appeal was neither desirable nor possible. But the habitual repetition of that doctrine does not prove that it accords with the serious conviction of thinking men; for, as a close analyst of human character has aptly observed, "there are certain things which all the world goes on repeating, simply because they have been once said;" (a) and it may be that the apophthegm, "All Pathology is based on Physiology,"—become a household phrase in medical circles—is precisely a proposition of the kind. Now I believe that it actually is a proposition of the kind; and that, if its signification were closely c[illegible]d, its soundness would be generally demurred to. L[illegible] me proceed to justify this view of its character.

§ III. There seem to be three possible ways in which Physiology may be conceived to hold scientific relationship to Pathology. Physiology may be imagined to provide the means of establishing *à priori*, otherwise of predicting, the conditions of Pathology; or it may be supposed capable of explaining pathological relationships, when evolved; or, lastly, it may be considered as supplying a standard of comparison, and as suggestive of plans and measures, observant or experimental, for investigating pathological conditions.

(*a*) As regards the first of these pretensions, the prophetic, I have already intimated my belief in the powerlessness of Physiology. It must, in truth, be admitted that, by its agency alone, we can never advance beyond the simple demonstration of the primary truism, that if healthy action be interrupted, morbid action necessarily ensues, (just as, it might be affirmed, that a watch with a damaged spring will not work, as when that spring was in order;) but the what, the when, the how, the how long, the what for, and the where to, of the new morbid actions, are all matters belonging to the province of experience alone. Let us begin, by way of illustration, with the very simplest pathological phenomena—those in which mechanical function is predominant. Take the instance of a wound in the gall-bladder. We know from Physiology that the gall-bladder is meant to contain bile; and we can certainly logically predict, that if the containing-bag be suddenly pierced, (a), the contained fluid will escape more or less abundantly. But beyond that, our powers of positive prophecy fail; we could not, except as the result of clinical experience, in any wise or in any degree affirm, what the results of the effusion of the bile might be. Take, again, the instance of an aged person, the neck of whose femur suddenly snaps: Physiology might certainly justify us in the positive affirmation, that inability to use the limb for progression would follow the accident; it might by diligent consideration of the precise lines of action of the various connected muscles (admitting this knowledge to be perfect in its way) make a correct assertion, prior to experience, as to the unnatural direction the limb would assume. But all this is merely mechanical; it is the sort of inferential power which would indeed prove Physiology to be the formative basis of Pathology, were man a mere machine. But he is not simply a machine; his femur cannot be broken without vital action being disordered; and the sum total of physiological knowledge could never have established, prior to actual experience, the vital consequences, local and general, of that simple injury. No; scarcely, I affirm, could it have supplied even a solitary link of the great chain of impressions which, originating in the disruption of a few minute nerves, vessels, and bone-lamellæ, may eventually make themselves felt in every fibre and every function of the frame. Again, Physiology would enable us to affirm, prior to actual experience, that if all entry of air into the lungs were suddenly arrested mechanically, death must almost instantaneously ensue. Vital reactions have no opportunity for complicating the problem. But make the obstruction less complete,—make death less instantaneous, and less purely mechanical,—give time for vital force to come into play, and what comes of the physiological gift of prophecy? What physiology could, prior to experience, have taught us the functional differences that ensue, where œdema of the glottis, laryngitis simple or diphtheretic, phthisical, cancerous, or syphilitic, extrinsic pressure from solid tumour or from aneurism, are severally the causes of mechanical obstruction? (b)

No; once vital action steps in, Physiology is

(a) Montesquieu.

(a) If perforation be *slowly* effected, it is almost needless to observe, that even this limited prophetic power is lost.

(b) Illustrations may similarly be taken from the varying effects of sudden mechanical section, and slowly-produced breach of continuity of nerves, and of the spinal cord, &c.

posed. For, to take the most favourable example for the exercise of its faculty in regard of such action,—that of a simple vital property, say, muscular irritability,—let it be granted that Physiology, having thoroughly analysed this property in regard of the quality of its natural stimuli and the phenomena and immediate effects of its healthy action, is in a position to foretell absolutely the direct and essential influences on itself of its exaltation, impairment or perversion; still for all practical purposes of pathological and clinical prophecy, the power will prove abortive and valueless. For in nature muscular irritability is not a condition that suffers alone,—that property is changed in connexion with others; in connexion with innervation, too, and structure; and hence the effects of its perversion vary from those which (on the admission made) could have been anticipated. The clinical coexistences of the perversion are as far beyond the prophetic ken of Physiology, as though this knew naught of the simple property. Besides, the admission made is, in reality, one which the pathologist is not called on to make. On the contrary, the conditions of muscular irritability have not been fully explored by physiology, if trust may be placed in recent pathological inquiries. Physiology, in truth, had not prepared us for the singular circumstance (established, to all appearance, satisfactorily, by numerous and careful experiments on man and the lower animals in a state of disease), that in certain morbid conditions the voluntary muscles will respond to, and act under, the influence of the will, while they refuse to obey the ordinary extrinsic stimuli,—while they remain motionless under the passage of a galvanic current, for example, though the conducting power of the muscular tissue has undergone no impairment. (a) Turn from a vital property to a simple function,—local innervation. The finer nervous filaments are so constantly accompanied by blood-vessels, that it is maintained the nerve and vessel are physiologically but one;—the integrity of the vessel and its contents is essential to the action of the nerve; unless blood flow in healthy proximity and abundance, beside the nerve filament, the action of this is at an end. Yet, look upon that woman, pale, marble-like, inanimate. Naturally possessed of ordinary powers of hearing, she has just chanced to lose some pounds of blood by hæmorrhage,—her life is in imminent danger,—her vessels seem drained of their contents,—a filiform pulse remains alone, to show that a dwindled current still trickles through her artery; yet her hearing is hyper-acute. She, who heard simply like other people, when her blood and nerves stood in natural relationship, is now distinctly, and almost painfully, alive to the slightest whisper at the further end of a large room, when her frame is quasi-bloodless. Could Physiology have predicted this condition of the auditory nerves? Could Physiology have foretold the mysterious influence that saves those nerves from impairment of functional power, (the brain is even anæmiated, for the sufferer is in a constant state of semi-syncope,) amid the general wreck of the vital fluid?

Consider next those varied combinations of altered texture and impaired function, known clinically as morbid processes and diseases. Does the mantle of the prophet belong more rightfully to Physiology in regard of these, than of the simpler phenomena we have just referred to? Think not of the absurdity which seems to lie on the very face of the question,—absurdity because that, which fails in regard of elementary phenomena, can scarcely be expected to succeed, when these are complex in infinite variety and sequence: think not of this, but appeal to the decree of experience. Is there, then, in the whole range of diseases, general, diathetic, and local, one solitary instance whose phenomena and whose pathogeny, from first to last, might have been foretold prior to experience, by any existing, or any fairly conceivable knowledge of Physiology of texture or function? That no such malady exists, from the simplest inflammation to the most complex blood-disease, is so completely a matter of every-day observation, that to illustrate the fact by examples would be an absolute waste of time. Yet, in spite of this, men have occasionally been found to act, as if the process were natural, and easy of execution. Men have actually ventured to fashion (and give names to) diseases, by grouping together morbid phenomena in such union, and in such sequence, as, from physiological considerations, they are led to imagine those phenomena *ought* to arise. In such manner did Cullen produce his description of "synocha," or pure *idiopathic* inflammatory fever, a disease which he acknowledged he had never seen. (a) Yet (such is the weight of authority in Medicine) notwithstanding this acknowledgment; notwithstanding the admission of Cullen's successor, Dr. James Gregory, that, during thirty years, he, too, had never met with synocha; notwithstanding the analogous statement of Dr. T. Bateman, and notwithstanding that clinical experience still looks in vain for the disease, various systematic writers continue to describe this creature of the imagination as an observed and observable reality!

But, further than all this, physiological *à priori* Pathology, finds idolaters who yield it still higher powers,—who assign it the function of announcing, prior to experience, the conditions and effects of various infractions of hygienic rules. Physiology, in other words, has been, and is perpetually, made to teach (what is to the tenth power, perhaps, more difficult) prophetic Ætiology. An example or two will show with what success. Not many years ago, a Committee sat in the House of Commons, for the purpose of inquiring into the effects of factory labour on adult, and especially on infant, health. Medical men were examined in numbers,—men of zeal, of honour, of accomplishment. But they chanced to be physiological ætiologists; they were men who denied the necessity for seeing the localities, watching the mode of working, scrutinising the habits of the workers, and, above all, substantiating the actual condition of the nutrition and innervation—the life—of those concerning the influences of whose occupation on health they were required solemnly to pronounce. Idle toil! They had philosophy and physiological dogmata at command; they knew much about oxygen and carbonic acid, imperfect oxidation of the blood, floating flue, and bronchial irritation, late hours, over-work, imperfect hæmatosis and mal-nutrition. And, armed with such philosophy and such physiology, they went to work. The results are recorded, and what are they? Why the system of man is scarcely exposed to an ailment, that was not, by one or other of the physiological ætiologists announced as an inevitable effect of the pursuit of the species of labour in question. Let me not weary your patience by rehearsing the series. It will answer our purpose to refer to three kinds of affection concerning the necessary frightful prevalence of which all were agreed,—namely, scrofula, deformity of the limbs, and flattening of the plantar arch. The sentence went forth, and was accepted for the time. But by-and-bye men who had actually occasionally seen factory children, and had not noticed the universality of the visitations announced, thought it might be as well to inspect a large body of them carefully, with a special view to the detection of scrofula, deformity of the limbs, and flattening of the plantar arch. Dr. Holme, for instance, (a name which should never be heard within these walls without a feeling of the deepest and most respectful gratitude) examined 401 factory children, and found eight only of them scrofulous. Mr. Harrison passed 1656 in review, without finding a single example of deformed limbs; and Sir David Barry inspected the feet of 111 girls, without stumbling on a single flattened plantar arch. It was absolutely found that the factory population was freer from some of the evils they had been so lavishly accommodated with by the prophetic ætiologists, than the population of the surrounding towns at large.

Let me offer you another illustration. Ramazzini (sound though he generally was, in his judgments) occasionally sinned logically by describing on mere *à priori* physiological grounds the influences of certain trades on health. He erred thus—for instance, in regard of tobacco-workers; and Cadet, Patissier, Percy, Mérat, and many others, followed in his train. Now, among the effects ascribed by these writers to the occupation referred to, appear habitual headache, vertigo, nausea, sneezing, vomiting, colic, and affections of the lungs (asthmatical and other), tremors, narcotism, bloody flux, discolouration of the skin, emaciation, and actual death. Reading these portentous statements (and I have positively put them below the actual mark), might not one suspect that an indictment for homicide fairly lay against men who habitually indulged in the use of snuff and tobacco? Might one not marvel how the existence of these luxuries, as cheap purchaseable commodities, was to be explained? Parent-Duchâtelet arose, and solved the mystery. He examined, either personally or through competent unprejudiced agents, 4518 men employed in the tobacco manufactories of France; and he found, simply, that these men did *not* suffer from nervous ailments, *nor* from chest diseases, *nor* from abdominal complaints, *nor* from emaciation, *nor* from discolouration of the skin, more than the community at large; that, further, their ordinary duration of life was below the usual average—nay, that the dismissal of workmen *in consequence of advanced age* was a frequent occurrence! Ramazzini and his copyists forgot altogether (that which nothing but experience can teach the precise influence and effect of in any particular instance,) the great *law of accommodation or habit.* (a)

(a) It will be seen that reference is made to the recent experiments of M. Duchenne.

(a) Vide Bartlett, on the Fevers of the United States, Pref. p. x. Ed 2.

(a) This law of accommodation is not only systematically kept out of view (or at least neglected) in the consideration of such ætiological questions as those just referred to, but forgotten in the estimation of the influence of already developed morbid states in generating others. I may, perhaps, be permitted to refer for an illustration of the latter point to observations elsewhere made (*Lancet*, March 17, 1849, p. 280,) on the presumed connexion between hypertrophy of the heart and cerebral hæmorrhage. Ought this law of accommodation to be lost sight of, when experience shows that certain morbid states, commonly producing (and originally having produced,) a given set of symptoms, may actually become necessary to their prevention? M. P. Berard removed a portion of a large meningeal tumor from a man, who at the time was perfectly free from symptoms of compression of the brain. The moment the morbid mass was cut away, and pressure thus taken off the brain, the ordinary symptoms of compression came on; nor did they disappear till pressure was made with the hand, so as to imitate that exercised by the morbid growth.

(*b*). Secondly, the pretensions of physiology to explain and connect the phenomena of disease, as actually observed, present themselves for consideration. This is a species of pretension, *primâ facie*, not illogical, and hence more likely to be well-founded, than that we have just dismissed. And it actually is better founded; many of the simpler departures from health, and especially many perversions of single functions, may be plausibly explained by the current notions of physiology: of the latter, Dr. Marshall Hall's beautiful and deeply philosophical system of excito-motory innervation furnishes a striking example. But there is an abrupt limit even to this power. I fear that, in regard of the more complex diseases, physiology is no more an Œdipus, than it, upon inquiry, proved a Cassandra. That physiology cannot explain the whole sequence of events, and relink, throughout the broken chain of necessary and contingent circumstances, of any given disease, is unfortunately the veriest of truisms: still, it enables us, here and there, to seize a causation, and establish a nexus,—no small triumph. We have then, legitimately hope in store for the future. But what seemingly unfathomable mysteries sleep in the depths of that future! Look to the laws of disease, as determined by observation, and (limited as our determination of these, in proportion to their true number, has been) say, what physiology shall penetrate the obscurity that encompasses their being. Glance at the class of virus diseases; what light does physiology throw on the spread of the virus of syphilis, on the order of its secondary and tertiary phenomena, on the special characters of each? What physiology makes clear the reason, why the virus of plague should seize on the lymphatic glands, of typhoid fever on the intestinal glands, of influenza on the organs fed by the pneumo-gastric nerve? What physiology will give demonstrative explanation of the fact, that some morbid changes (as, for instance, calcification of the arteries) affect the body symmetrically? How shall we learn from physiology why blood-diseases, such as cancer and tubercle—(with their, in some sort, prototypes, chronic poisoning by lead, iodine, spurred rye, &c.)—infect some organs rather than others, some parts of those organs rather than the rest of their substance, —why they fix upon one organ at one period of life, and in one sex, and attack other organs at other periods of life, and in the other sex? Can we hope to ascertain, through physiology, why ulcerations of the small intestine are almost absolutely limited, among chronic diseases, to the syphilitic and tuberculous diatheses, while cancers may grow in abundance in the frame, and yet the continuity of that bowel remain unharmed? Why, again, inflammations of continuous textures become limited;—why bronchitis, for instance, except under peculiar circumstances, does not pass into pneumonia;—why rheumatic endocarditis, unless in excessively rare cases, stops short at the sygmoid valves, and affects neither the pulmonary artery nor the aorta;—why general peritonitis is a thing almost unknown? What says physiology of the periodicity of disease —of the nature of constitutional aptitude or predisposition to various maladies? Does it explain very readily why, in a certain proportion of all primiparous women a membraniform plate of bony matter forms between the cranium and dura-mater? But enough; let me not weary you by a multiplicity of such illustrations—their name is Legion. Doubtless, time will give the answers to some of these enigmas; and, doubtless, physiology will, *in the manners to be presently mentioned*, aid in the search for them. But how greatly more necessary to their probable, and how essential to their positive explanation, is the comparison of a large number of accurately observed instances of the diseases themselves. Meanwhile, reflecting upon these mysteries, are we not reminded of the poet's phrase,—"Truth is strange, stranger than fiction"? Yes gentlemen, laws, as observed, are stranger than principles, as imagined; the realities of pathology are stranger than its romance.

(*c*). Thirdly, physiology may be considered as suggestive of points of inquiry in pathology, and as establishing a standard of reference for morbid conditions and processes. Now here are, I believe, the true functions of physiology in regard of pathology; here the field is peculiarly its own, and here the good it may work out is almost incalculable. On some occasions suggesting points altogether novel for the investigation of the pathologist, at others giving a new aspect to facts deemed familiar, and in either case lending zest to inquiry; in this sense it is that advances in physiology must almost of necessity, immediately or more remotely, contribute to advances in pathology. In this sense it is, that he who labours in the former, is sowing seed which, in due season, shall bear fruit in the latter. In this sense it is, that sound physiology promotes sound pathology. In this sense it is, that the hymn to the merits of physiology can neither be too loud nor too long. In this sense it is, that I shall have repeated occasions in the progress of the course to draw your attention to our debts, past and positive, future and probable, to physiological science.

Let me here anticipate with a single illustration it will sufficiently exemplify the manner in which *à priori* and *à posteriori* pathologists severally avail themselves of discoveries in physiology. An acute physiologist, M. Bernard, had been led by experiment to infer, that the production of starch-sugar is constantly going forward in the healthy state in the substance of the liver, quite independently of saccharine or amylaceous diet,—that, in fact, sugar-formation (like bile-formation) is a function of the liver. Subsequently, he discovered that section of the par-vagum immediately arrested this formation of hepatic sugar. Here was materiel to arouse the attention of pathologists. How, if at all, were these announcements applicable to the pathogeny of saccharine diabetes? Certain pathologists of the physiological school have already answered the question. In their eyes the mystery hitherto attached to diabetes is gone;—they argue thus: if sugar be naturally produced in the liver through the influence of the par-vagum, that disease clearly consists in simple excess of a natural secretion, and that excess is as obviously dependent on undue stimulation of, and by, the controling nerve. In a word, saccharine diabetes may henceforth be defined to be a hyper-innervation of the pneumo-gastric nerve. I have heard this said,—statements tantamount to this have been printed. On the other hand, pathologists of the observation school proceed more cautiously; they would say, (granting, of course, that M. Bernard's physiology is sound,) here is a new element of healthy chemico vital acts in its general signification deeply important, and having some probable, or at least possible, connexion with diabetes. Here, too, is evidence of the necessity, in all cases of that disease, for the clinical consideration of the pneumo-gastric nerve. But they would not attempt, prior to experience, to draw any positive conclusion as to the part (if any) played by that nerve in generating the malady. They would argue (the healthy influence of the nerve being fully admitted:) it may be, that diabetes depends on hyper-stimulation or perverted action of the nerve; or it may be, that it depends on disease of the connected portions of brain; or it may be, that the undue accumulation of sugar in the blood is a consequence of a primary change in the liver itself, whereby it yields an excess of sugar to a natural amount of nervous influence; or it may be, that the blood circulating in the liver is in such a state as to lend itself with unnatural facility to sugar-formation; or it may be, that the nerve, the liver, and the blood, are natural in regard of the sugar-producing force, but that, from some defect in respiration, the sugar formed is not oxidised in the lungs with sufficient ease and rapidity. They would maintain, that observation alone could decide which, if any, of these hypotheses was correct; and they would regard M. Bernard's results as having furnished a new standard, and suggested a new path of inquiry, but not as having determined the nature of diabetes, prior to experience.

§ IV. If the legitimate application of physiology be thus limited, why, it may be asked, has the attempt to found pathology on physiology, prior to experience, always proved, both with authors and readers, teachers and disciples, so singularly popular? Nine conditions occur to me as having mainly operated in this direction.

An obvious cause of the popularity, the system has uniformly enjoyed, is the fact of its saving trouble. There is, probably, no more laborious intellectual employment in existence, than the effort to work out, by clinical observation and interpretation, the laws of any given disease. It requires a combination of powers of physical and moral endurance and mental capacity rarely meted out to the same individual. Constituted, in truth, as man is, by nature an indolent being, is it to be wondered that when presented with "first principles," whereby he is empowered to fix the origin, course, and issue of diseases; and, independently of direct labour of any kind, but simply through a musing, *dolce far niente*-like exercise of his reasoning faculties, to mould them into such forms as may best suit his purposes,—is it to be wondered, that he seizes with avidity on the complacent instruments, and eschews with determination the severe and rugged toil of direct observation?

But, secondly, not only do these principles save labour to the original investigator, but to the learner. They are a precious and a facile *Memoria Technica*. Few memories can retain an accumulation of generalised facts or laws, no matter how interesting or important they may be, unless by constant exercise and perpetual reference, either simply mental or direct, to the objects referred to by those laws. Here, then, is labour again involved. But, with a supply of physiological "first principles" at command, the dependent facts of pathology string themselves in readiest order; or, if the memory be hopelessly sluggard, the principles are there to reproduce the facts at will. The only drawback is, that as the solidity of the principles, and hence of the facts, owing them paternity, may be questioned, the advantage of readily recalling or reproducing these is more than problematical.

But physiological principles serve, it is argued, as guides, prior to experience, to the determination of unknown pathological conditions; and hence a third source of their popularity. To their *investigation*, yes; to their *determination*, no; observation must intervene. In fact, the argument, though just in foundation, is a sophism in its application. That in a new and difficult path a guide is an desirable thing, is a position, abstractedly stated, which few will dispute. But the utility of any particular guide must, as of all other things, depend on fitness or unfitness for its purpose. Suppose ourselves travelling in a new country, and desirous of ascending a mountain peak, at all times difficult

of approach, but the ascent of which has by land-slips, changed course of torrents and avalanche-falls been recently rendered a new and more complicated problem. Guides present themselves. They may be of three kinds. Men may crave to lead you, who honestly confess they have not been the way since the occurrence of the changes. But they assure you emphatically, that, from their acquaintance with the natural conditions of the mountain passes, the course of the rivers, the tracks by which avalanches *must* fall, and so forth, they can form a complete and perfect notion of the changed conditions they have never seen. They can deduce the possible pathology of the passes from their physiology. You probably pay such persons as these a compliment on their sagacity, (as estimated by themselves,) but decline to place your flesh and bones at their disposal. Or a second group may solicit the honour of conducting you; and, upon inquiry, you learn that these aspirants have not only not explored the altered mountain routes, but have settled among themselves to guide you on a plan that (under circumstances of mountain convulsion, more or less similar) has proved over and over again a fallacious one. You pronounce them to be impostors, and suspect their motives. You feel that the guidance offered by both these groups is shadow, not substance,—that they have made no further advance than yourselves to the desired haven; you feel that in common with yourselves they have the laborious path of experience to tread. But a third group of guides may offer, who, as before, so likewise since the changes, have made the ascent many a time and oft,—men to whom each step almost in the path is by experience familiar. To the superiority of these you bow; to them you confide yourselves in all security; they are guides not alone in name but in reality.

And so in the difficult and untrodden routes of pathology, three classes will propose to guide you in the determination of new conditions. Men who have no experience of the regions in which they purpose to lead, but who believe honestly in the perfect aptitude of a new species of theory to serve in lieu thereof;—men who are not only devoid of that express experience, but who, in defiance of past example and warning, would guide you by a worn out species of theory, to inevitable error;—and men who, having that experience, know the route to truth. And of the former false guides in pathology, or principles prior to experience, those rising with largest and most hopeful promise, have ever set behind the most hopeless failure. Soaring brightly aloft like rockets, they have fallen darkly like their sticks. Archæism, Pneumatism, Animism, Stahlianism, Hoffmanism, Cullenism, Brownism, Contra-stimulism, Broussaisism! Ye guides of the hour; ye blind that led the blind for a season! say, even now, before the personal memory of some of your authors has passed away, say what verdict does posterity pronounce on the quality of your guidance? Alas, posterity is pitiless and stern; it thinks naught of the genius, and ambition, and positive services of your authors,—it simply proclaims that you arrested all progress in true knowledge for the time, and in the quarters your guidance was trusted to!

Fourthly, physiology is very constantly assigned the merit of establishing pathological facts and doctrines, which in reality it has had no share in substantiating. An apt illustration occurs in a recent work, by one of the first physicians of the day, whom I am proud to call my friend, and whose admirable style almost redeems (what appears to me) the oversight in the thought,—as choice setting gives somewhat of the value of the gem to the imitation. He observes:—"Every physiological physician knows well that a morbid condition, which may have been months or years in forming, can only be effectually and permanently removed by means which act slowly and for a length of time, not on one part only, but, more or less, on the whole system." (a) Now, the general doctrine here broached (although exceptions might readily be cited) is in accordance with observation. But, obviously, the credit of establishing that doctrine should be assigned to pathological, not physiological, observers. What physiological facts are known, justifying the assertion, even as a probability, prior to experience, that morbid conditions, slowly built up, can only be slowly thrown down? All that is positively known of the rapidity with which waste and change of tissue are physiologically effected, would rather warrant the expectation of sudden removal of long-existent disordered states being easy of accomplishment, when once the right impulse was given. But pathological observation has proved that (in the present state of therapeutics, at least) the reverse is the rule; while the laws regulating exceptional cases furnish a very curious subject of inquiry.

So, too, it is the habit to class the now popular investigations into the morbid conditions of the blood with physiological researches, though their distinguished re-originator, Andral, gave the hint of their true character in the terms "*Pathological* Hæmatology."

Again, somewhat similarly, a large proportion of experiments on living animals, essentially pathological in their character and aim (as, for instance, those consisting in the injection of various noxious substances into the blood-vessels,) are confounded, under the general name of physiological, with others really deserving this title. Now, the effect of this misnomer is, that when perchance the former class of experiments leads to suggestions available in the direct investigation of disease, physiology, instead of experimental pathology, unfairly receives the credit.

Fifthly. An artifice very commonly resorted to by physiological pathologists, has contributed not a little to throw a false glare of wisdom over their *à priori* modes of divining the conditions of morbid phenomena. From alleged speculative examination of certain groups of physiological facts, they set forth a certain principle of pathological action. The principle created and announced—let us look around, say they, for illustrations; and, behold, these are not long in coming. Who can feel disposed to scrutinise sharply the logical quality of a system that leads to such startling results? Who is not rather disposed to bend the head irreflectively before an intellectual procedure of such seemingly high stamp? Observe what it would signify. A man from the workings of his brain on actions of *one kind* creates principles that must regulate actions of *another kind*,—and finds in the ready illustrations that present themselves, the proof that Nature has precisely the same views on the matter as himself,—that, in other words, he is possessed, *quoad* intellect, of creative faculty. Beautiful and wondrous indeed would the process be, were it only honest and true! But has it these qualities? Divest yourselves of the obsequious spirit of admiration, and assume the cold judgment of the critic, and I fear you will find that it has not. You will, I think, discover that in such cases the real course of proceeding has been this. A single fact has been caught up, of a novel or ill-appreciated kind; that fact has been generalized at once; and this generalization is the putative *à priori* principle, the *quasi*-offspring of a creative faculty. So that, if this anatomy of the pseudo-creation be correct, the whole process resolves itself into elements of the following species: a fact due to observation; an inference from this, belonging to a very vicious class of sophism, the *argumentum à particulari ad universale*; and, lastly, a conversion of this imperfect *à posteriori* inference into a baseless *à priori* principle. Is it not plain that the process sins logically? Does it not strangely remind one too of a sleight-of-hand *coup*,—a sort of intellectual leger-de-main? Quick, presto, it is done,—your fact is a principle!

Sixthly, more crafty still are they who throw off *à priori* applications of physiology to pathology, and look not for illustrations, and care not for acceptance at the moment. Time, they mysteriously hint, will judge them. As the world advances in observed wisdom, facts will come to demonstrate that the Deity has given to some men intuitive prescience. Well, time flows on: the oracles are forgotten. But at length, perchance, some observer, in the course of investigations, wholly without reference to, or knowledge of, the bygone divinations—on grounds completely different, with aids as dissimilar, through philosophy egregiously opposed,—comes to results in some sort according with, or corroborative of, the oracles that have slumbered. Then comes the *cantus triumphalis* of the augur. Behold! I said it—I divined it—years before your dull observation had started even the terms of the problem, my principles had worked out the solution. And with lusty voice the crowd sings chorus. But is this right? Ought the crowd to lend their harmony of praise? Is the seeming merit all real? Is there no artifice here also? Does the crowd remember, did it ever know, the multitude of instances, in which similar divinations have been made, have failed, and have slept the sleep of death? Must not the crowd, when reminded of these, admit that the triumph is signally like that of the professional fortune-teller, who, wrong fifty times, comes right, she knows not why or wherefore, the fifty-first? And lo! a present miracle, exclaims the gentle candidate for a "fair or a dark man;" while the philosopher aside knows that an occasional successful hit is a matter of necessity, the frequency of which may be determined by mathematical calculation. No; it is not he who starts possibilities, or even probabilities, on illogical grounds, but he who by logical inference converts possibilities into certainties (positive or negative) that, unless I deeply err, deserves the homage of his fellows.

Seventhly, people are dazzled by the wondrous, almost miraculous, appearance of progress in pathology, which the direct application of physiological speculation occasionally effects. Chemical physiology, which has of late taken the lead in this point of view, deserves particular notice here. It seems to have taken that lead, first, because one or two chemists (men of singular mental power, and, like the Chemi-Iatrists of old, chemically in advance of their age) gave the impulse; secondly, because it has all the charms of novelty; and, thirdly, a section of pathologists seems to seize upon it, because (singular contradiction!) they are more or less unacquainted with the qualities of its alleged facts. Accepting these facts from others, unconcerned in reputation by the correctness or incorrectness of these facts, blind to the difficulties of their establishment, uncognizant of the host of uncertainties pervading the very atmosphere wherein they originate, this section of pathologists manages these facts (or pseudo-facts) in the

(a) The Physician's Holiday, p. 268. By John Forbes, M.D., &c., &c. A work abounding in varied beauties of thought and expression.

beatitude of innocence; and the man who, as a clinical observer, would hesitate to pronounce positively on the characters of a symptom or a physical morbid change, where any source of fallacy existed, although he had examined it scores of times perhaps, welcomes, as absolute truths, chemical inferences essentially plunged in obscurity and doubt. His conscience is at ease, and away he works. And while no complete or trustworthy analysis of a single morbid product, in accordance even with the nascent organic chemistry of the present day, *exists*; while masses of matter are thrown on one side under the title of extractions, or, as one might baptise them, the "great unknown;" while the very constitution of protein is matter of dispute; while one of the first organic chemists of the age (Dr. Prout) "knows at present of no apparatus or means of operating, capable, where azote is concerned, of unequivocally deciding about the presence or absence of *one proportion* of hydrogen or even of oxygen in a complicated body" (on Stomach, &c., 4th edit., p. 556), and "is satisfied that very few, if any, of the formulæ now so much in fashion with chemists, represent the true constitution of organised substances" (ibid. Preface, p. viii.); while the alkaline reaction of the blood, even, was yesterday referred to one salt, is to-day traced to another, and will to-morrow, in all probability, be affiliated to a third; while we know, that of certain substances entering into the blood by absorption, all chemical traces may be almost instantaneously lost, though, when the same substances are mixed with dead blood without the body, those traces may be readily followed; while all these evidences of imperfection (and they are but a brick of the Babel) stand forth in warning reality, men are found to pretend that pathology is to be based on chemistry, prior to experience, and that the votaries of eclectic observation are to bow to its dictates! Here appear men, who (just as if they asked for a piece of Prussian-blue) will most readily undertake to make pus, or cancer, or tubercle, at a moment's warning from any tissue-detritus or exudation you please,—all they want is the temporary loan of an atom or two of oxygen, or hydrogen, or nitrogen, as the case may be. No, gentlemen, place no confidence in these figments of an overheated fancy. Even if they seem to accord with the results of experience, they are only possibly, not necessarily, just; if they fail to accord with those results, they are necessarily inapplicable for pathological purposes, if not necessarily unsound. Besides, it is not the higher order of chemists, who produce, or encourage the production of these fanciful syntheses. Did *they* profess, that such applications of chemistry were sound and just, it would be hazardous to contest their scientific quality. Still, some chemists of most brilliant repute have promulgated chemical theories of diseases, unchecked by observation; and so given, indirectly, a colour of justification to the wild exploits just referred to. As a single instance, let me offer you Professor Liebig's hyper-oxidation theory of phthisis,—striking, simple, plausible, attractive, in seeming vastly progressive, wanting nothing but the confirmation of clinical observation,—but when submitted to that test found, as is now known, to clash with obvious facts, and therefore (whatever excellence it possesses as a piece of profound chemical inference) inapplicable to, and inadmissible as a portion of, the natural history of disease.

Eighthly, the tendency to found pathology directly on physiology may be traced to the apparent plausibility of the attempt. Physiology studies the actions of the frame in health; pathology studies the actions of the frame in disease. The knowledge of the discords, an instrument is liable to emit, and the modes of correcting these, are matters of direct inference from the knowledge of its concords; and, similarly, pathology must be matter of direct inference from physiology. But, after all, here is nothing more than a specious sophism. Speaking abstractedly, it may be perfectly true, (and absolutely must be so,) that pathological action, no matter how complex, is a derivation from physiological action, simple or complex; but the question is to be considered practically. Now, we have already seen, if the statements of fact I have made be just, how little can actually be ascertained of the laws of disease by this method; and, if you consider, for a moment, what a human being is in his physiological actions, you will hardly wonder that it should be so. Look upon one of the most elementary chemico-vital series of acts we know of—the birth, life, and death of a secreting cell. Consider the myriads of such cells concerned in the production of but a few drops of secretion; conceive them, at their various periods of healthy existence, influencing, as they must, physically, chemically, and vitally, not only the locality they occupy, but (through the blood and nerves) parts more or less remote, and say, what can we predicate with safety of the precise nature of those influences, what of the re-actions which those influences excite? And yet we would presume to lay down, prior to experience, the effects of those influences when deranged,—and not only when one set of such influences, but when multitudes of them, are deranged, —when acts of a complexity beyond conception err, acting, re-acting, advancing, retrograding, yielding, clashing, in endless varieties of confused combination. Alas for him that arrogates here the gift of divination, and fancies he can, through physiology, forejudge the issue of the mishaps of even a single set of secreting cells. Lending himself prescience, he is really no more cognizant of God's providence in this matter, prior to experience, than the sauntering school-boy, who, throwing stones in the stream, dreams not what effects the motion of the ripples he idly watches, as they circle to the bank, produce through the atmosphere of the earth. (a)

Lastly, an impression appears very prevalent that the direct application of physiology (physical, chemical, or vital) to pathology is peculiarly philosophical or "scientific;" while the direct observation and interpretation of the phenomena of disease scarcely possess a claim to that dignified title. Hence a ninth source of the popularity of the former. Louis, for instance, from the sustained critical observation of years, accumulated a series of individual facts, whence he induced a natural history of phthisis, finally establishing that history in regard of the points, and under the circumstances, examined. But he ventured not even on an hypothesis as to the essence and pathogeny of the disease. On the other hand, an eminent chemist, studying the laws of the oxydation of tissue in general, passed through a series of analogical inferences, treated them as if they were established truths, and propounded the theory of the disease already alluded to, without professing ever to have observed it. Now I have repeatedly heard it said that the treatise of Louis had certainly great merit, as a work of observation; but that its author was not a man of science; while the great chemist's science was so profound, so expansive, and so ductile, that he might well dispense with observation. When it was urged, in reply, that the conclusions of Louis were solid and unimpregnable,—time-marks of progress in man's knowledge of disease; while the hypothesis of the great chemist flashed brightly for an hour and was gone, the rejoinder was still the same, heads were shaken, and the chemist was still pronounced, *in regard of this matter*, the man of science.

What, then, is science, and what constitutes a science? I cannot, for my part, conceive a science to be anything more or less than the sum total of the established generalizations belonging to any particular kind of phenomena, classified according to their resemblances and their differences, their alliances and their repulsions; generalizations which, in turn, cannot be formed from any possible data, but from the comparison of accumulated individual phenomena of that kind.(a) It seems logically impossible to imagine any other mode of formation of a science. Now, if this be true, all facts and generalizations belonging to sciences, collateral to that under investigation, no matter how close their relationship, can form no part of itself, as *matter of necessity*. And their direct transference from the one to the other—the attempt to introduce them from the one into the other as *part and parcel of itself prior to experience*—is a flagrant breach of logic,—a proceeding based on the assumption, that, because a thing is possible or likely, it is actual and real. It matters not how perfectly just any given principle is in connexion with facts of its own order, and how fully it answers the conditions of a scientific law,—the moment it is transferred, and applied in the guise of an established principle, to facts of a different, though allied, order, as great a breach of logic is committed (and how can science exist, where logic is wanting?) as if the principle were divested of all claim, in its original position, to scientific character. If this be true, and I think it would be difficult to prove it false, it is he who observes, interprets, compares, and classifies facts and laws of any particular order, and not he who makes direct application of inferences from facts of one order to facts of another order, that is the true labourer in the cause of science. And let it not be supposed that, because physiology (chemical as vital) will advance as time flows on, that its claims or powers to form pathology prior to experience, will ever change. Pathology, too, will advance, both independently, as it hath hitherto done, by pure observation, and, dependently, in company with physiology and the other collateral sciences, through the suggestions they offer, but not through the *à priori* principles they are made to force upon it. The mode of searching after truth can never change; what is real now in the philosophy of establishing a science will be true to all eternity.

To illustrate this argument, and give greater precision to its bearing. Let it be supposed that any given chemical law has been established by observation in regard of certain healthy actions. That law constitutes, henceforth, an element of the science of physiological chemistry. But it may, or may not, hold in regard of those actions when diseased.

(a) I cannot resist the pleasure of justifying this illustration by an extract from the writings of a man who possesses, in the rarest degree, the art of throwing a character of poetry over the profoundest truths of science—the inventor of the Calculating Engine:—"The waves of the air, thus raised, (by the human voice in speaking) perambulate the earth and ocean's surface, and, in less than twenty hours, every atom of its atmosphere takes up the altered movement due to that infinitessimal portion of the primitive motion, which has been conveyed to it through countless channels, and which must continue to influence its path throughout its future existence."—*Babbage; Ninth Bridgewater Treatise*, p. 110.

(a) Reference is of course made especially to *natural* science; but the statement given will, I believe, apply fully to *abstract* science also.

It is for observation to determine this. The physiological law is merely *a candidate for a place* in the science of pathology, to be accorded or denied it by observation. Applied directly from physiology to pathology, it degenerates from a law into an hypothesis; and no hypothesis can ever form actual part of a science. On the other hand, hypotheses are never to be disdained; like servants, of whose character we are doubtful, they are to be taken on trial. Of hypotheses I would say, *accept none; reject none; try all*,—provided only they do not distinctly clash with any absolute law of natural or abstract science. But, in making this admission, I am desirous of not being supposed to imply, that the mere habit of starting loose conjectures is in my mind either useful or commendable. I consider it, on the contrary, a sufficiently vicious practice, diverting men's minds (if it exercise any effect at all) from the true sources of knowledge. It has become very much the habit at the present day, when objections are made to the hap-hazard system of chemico-physiological conjecture, to find them met with observations, something in this wise:—"What, you would denounce hypothesis! you forget, my good sir, that the existence of America was an hypothesis in Columbus's brain, before he proved its truth by experiment." As if every man, who started a conjecture, was, *ergo*, a Columbus; as if every conjecture contained an America! (a)

But, to return;—not only is there in many quarters a tendency to overrate the philosophical quality of direct introductions of the principles of one natural science into another; but a persuasion of the actual and essential inferiority of Observation as an intellectual instrument. One notion, which contributes to this low estimate of observation, is, that the principles of the physico-mathematical sciences were established without its aid, and are in fact either pure mental abstractions or mathematical results. But this is completely erroneous. In physico-mathematical astronomy Observation lies at the root of all acquired truths. "No one can doubt," says Mr. Whewell, "that in historical fact the laws of motion were collected from experience. That such is the case is no matter of conjecture. We know the time, the persons, the circumstances belonging to each step of each discovery." (b) Kepler's laws of planetary motion were primarily not ascertained even by induction, but by simple direct observation. We know from Kepler himself that, "before hitting upon the conception of an ellipse, he tried nineteen other imaginary paths, which, *finding them inconsistent with the observations*, he was obliged to reject."(c) Yet further, even the axioms of geometry are found, in ultimate analysis, to be experimental truths, generalizations from observation. Nay, more, as shown by Mr. Mill, "the science of number is no exception to the conclusion, that the processes even of deductive sciences are altogether inductive, and that their first principles are generalizations from experience. (d)

Rest satisfied, too, gentlemen, that observation is not in our science the humble drudge's toil, which the ante-experience school of Pathologists would persuade you to believe it. It is a sensual and intellectual process of the deepest and most varied

(a) The illustration is otherwise singularly inapt. Columbus was led by a system of inductive reasoning to his wondrous discovery; and had it been possible for him to make the experiment, before announcing the expected result, it is evident he would have done so,—the quality of his intellect was eminently Baconian.

(b) Philosophy of Inductive Sciences, i. p. 238.

(c) Mill's Logic, i. p. 363. (d) Ibid, i. p. 336.

difficulty. Remember (to quote the admirable words of one who has gained a commanding place in the philosophy of abstract science, Mr. Mill) "the observer is not he who merely sees the thing which is before his eyes, but he who sees what parts that thing is composed of. To do this well is a rare talent. One person, from inattention, or attending only in the wrong place, overlooks half of what he sees; another sets down much more than he sees, confounding it with what he imagines, or what he infers; another takes note of the kind of all the circumstances, but being inexpert in estimating their degree, leaves the quantity of each vague and uncertain; another sees, indeed, the whole, but makes such an awkward division of it into parts, throwing things into one mass, which require to be separated, and separating others which might more conveniently be considered as one, that the result is much the same, sometimes even worse, than if no analysis had been attempted at all."(a) Ponder, too, on these striking words of Sir Gilbert Blane:—

The truth seems to be, that a higher order of intellect, a more rare and happy genius, a more correct and better-tutored understanding, is required to elicit practical truths by observation than to coin theories."(b)

§ V. To conclude, gentlemen, my convictions on the main question, on which I have just addressed you, amount concisely to this:—That Physiology (physical, chemical and vital) cannot logically, nor hence scientifically, be used for the *pre-determination* of the conditions and laws of pathology;—that Physiology may logically, and hence scientifically (if excessive caution and judgment be exercised) be directed, subject to the control of experience, to the *explanation* of those conditions and laws, when established by observation; (c)—and that the essential function of Physiology in regard of pathology is *measurement and suggestion*; the supply of a standard of reference and the suggestion of points and courses of inquiry: while, on the other hand, on those tablets (a) are set down the sole *direct formative processes* of the science. These convictions I have acquired deliberately, and hold firmly; and I have ventured to express them before you with earnestness. In stating them, I have been obliged to trench somewhat on the departments of Chemistry and Physiology. But it is gratifying to me to believe, that I have not broached opinions which (as far as I can gather from the tone of their published writings) clash with the doctrines of those who, in the highest degree, represent those departments here and elsewhere. It is not, I believe, the acknowledged lords of the crucible and alembic, nor is it they who have peered most closely and most steadily into the mysteries of healthy life—it is not the Berzeliuses and the Grahams, the Müllers and the Sharpeys,—that will cry, Hold! because an attempt is made to set a limit to the illogical intrusion of their sciences into the domain of Pathology. . . . . But, whatever my views, I do not the less entertain personal regard and esteem for men who, urged by other views, conscientiously acquired, labour, in accordance with these, to widen the confines of our science and our art. Somewhat as, in the moral world, we visit with our reprobation the crime, rather than the criminal; so, in the intellectual, we may denounce what we conceive to be false in logic, while we cherish him whom we hold to be a pseudo-logician. In this spirit I hope myself to be judged. So long as we are all animated with the love of, and yearning after, truth; so long as we spare no toil to achieve it, our feeling for each other can be none other than of mutual regard and good brotherhood. No matter how different the paths which the various qualities of our minds, our physical constitutions, and contingent circumstances may lead us to pursue, we then all agree in this,—we are toilers after truth for the benefit of mankind. It is this very toiling after truth (the aspiration even more than the possession) that gives the stamp of dignity to our pursuit, and elevates the medical profession in the scale of humanity.

And herein lies one of the noblest attractions to that Profession, — an attraction as little tainted with selfishness, (at least of a low order,) as, perhaps, any human motive. It is a Profession on which worldly honours and lucrative posts are not showered. It is a Profession to which even the homage of lay respect is not uniformly conceded; men of education, men holding seats in the Senate of the land, are found to utter scoffing platitudes at our expense, because, forsooth, we are not omniscient,—the senatorial benches, they are in the habit of frequenting, doubtless teeming in the quality! Charlatanism, decked gorgeously in its unholy spoils, walks abroad in mockery of our science; and there is none to say it, Nay. Our veterans in the army are refused medals; our youths in the navy are denied the decencies due to their social standing. And (climax of incomprehensible indignity!) the Government declares us incompetent to judge and to guide in matters belonging to our own province. It is determined the Public Health shall be legislatively cared for; and forthwith persons (with a single exception) whose days have been passed in pursuits wholly unconnected with

(a) Op. cit. i. p. 438.

(b) Elements of Medical Logic.

(c) Any one who will reflect, without prejudice, on the past history of medicine, will, I think, be disposed to agree with me, that the passion for *universal and rash* explanation (the habit of looking for the *why*, and not the *what*, of morbid phenomena) has indirectly proved one of the most fruitful sources of its slow progress; an unsound explanation, once accepted, interferes to an indefinite time, with the discovery of the true one. Man feels within him, undoubtedly, a sort of instinct of causality; but it does not follow that he is always justified in obeying it. It is often one of the nicest problems to determine, whether, under certain given circumstances, the effort at explanation is, or is not logically legitimate. It may be, that a mental triumph is achieved by resisting that instinct, just as a moral triumph is achieved by a successful struggle against the baser animal propensities. Now, one essential to the admission to an explanation appears to me to be, that this should flow easily (as, of course, logically) from the premises; "The quality of *Truth* is not strained." The amount of effort expended, and of ingenuity displayed in framing any given explanation of obscure pathological existences is very frequently in the direct ratio of its fallacy. Instead of worshipping such ingenuity, as is the fashion, there would be deeper wisdom, I cannot help thinking, in regarding it, *quoad* results, as fraught with illusion and mischief,—as a promoter of spurious, and, *pro tanto*, a preventive of true knowledge. I would say to a youth, starting on the journey of scientific life,—whenever you have woven a web of explanatory theory, peculiarly delicate and subtile, and peculiarly gratifying to your *amour propre* in the matter of invention, deeply suspect your correctness,—nay, sacrifice the product of your brain at once, unless you know yourself to be possessed of that higher moral courage, which will enable you, after it has been given to the world, to surrender it without struggle, if proved unsound. If you fail to do this, the chances are strong, that your theory becomes your intellectual idol, turning you from the just apprehension of truth, even to the end of your existence, blunting your senses, and perverting your judgments. Such was the effect on his own intellectual being (and this was one of no common order) of Broussais' invention of the theory of Irritation. Cullen had the sense and courage to teach and practise the frequent sacrifice of his idol-theory of spasm; otherwise the memory of that distinguished man would have been but the reflection of error. And Cullen, in this partial relinquishment, stands almost alone.

(a) Vide p. 275

disease—men unversed in even the veriest rudiments of the science of life—are selected as the fittest instruments for dealing with the most intricate questions of practical hygienics,—as though incapacity were the father of usefulness!

Well, be it so! Notwithstanding all this, pursue the even tenour of your way, unruffled by these crosses. Dwell on the memory of that brighter side of the picture, I, a moment since, held before you Remember, too, you have the reward of moral distinction, and of scientific reputation, it may be fame, within your reach. Scarce shall your toil have added a new fact or a new inference to our science, before it goes forth to the ends of the earth, and your names may be marked ἐυεργετης in furthest regions. Your labour has borne fruit for the benefit of universal man, "no matter what colour an Indian or an African sun may have burned upon him;" your labour has united the families of the earth in the link of common obligation. Brilliant and soul-stirring reward!

That remarkable man, whose posthumous Memoirs are now appearing, clothed in a mystical solemnity, according with their fabled place of issue, "beyond the tomb,"—he who passed through well nigh every grade of social condition, at one time a vagrant outcast, at another ambassador from his own to the chief courts of Europe, and who, in his experience of the affections and passions, the vanities and ambitions, struck every chord of the lyre—Chateaubriand, I mean—tells mankind, that life offers but two real goods, religion and love. Yet would I plead for the reality of another, and that other not beyond *your* grasp,—the steadfast pursuit of true knowledge, and, through this, the ennobling consciousness of effort to aid in fulfilling the mission assigned your Profession by the immortal Descartes, when he said, (and no Government can blot out the words,) "If the human species can be rendered perfect, the means of that perfection are to be sought for in Medical Science. (a)

ORIGINAL CONTRIBUTIONS.

RETROVERSION OF THE UTERUS AS A CAUSE OF STERILITY.

By EDWARD RIGBY, M.D., &c.; Senior Physician to the General Lying-in Hospital; Examiner in Midwifery in the University of London.

Mrs. T., aged about 26; married nine years; mother of four children; the last was born eight weeks ago; had an abortion between her first and second.

Nov. 10.—Tall; fair; emaciated; face pale, with an occasional flush; nervous and excitable. Complains of great debility; bowels very irritable, and easily deranged by medicine; tongue glazed. Complains of a constant pain at the lowest part of sacrum.

Examination per Vaginam.—Vagina feels as relaxed as in a woman but a few hours after labour. Os uteri turned quite forwards, and very near to the symphisis pubis; uterus is inclined backwards, in which direction it is tender; uterine sound passes two and a half inches backwards and downwards. Replaced the uterus without pain, and the following day applied Professor Simpson's uterine supporter; it passed with great ease, and the displacement at that moment was so considerable that the uterus was nearly topsy-turvy; the uterus felt heavy, but the replacement of it produced little or no uneasiness.

℞ Liq. taraxaci, ʒi.; liq. calcis, decoct. sarzæ co. aa. ℥ iijss. M ft. mistura cujus sumat coch. magn. ij. bis terve die.

(a) The phrase runs in the original:—"Si l'espèce humaine peut être perfectionnée, c'est dans la Médecine, qu'il faut en chercher les moyens."

℞ Pulv. guaiaci magnes. carb. aa. gr. x.; M ft. pulvis om. mane ex aquâ sumendus.

Aug. 12.—The instrument does not produce discomfort. She has lost the pain in the sacrum from which she suffered. Rep.

Nov. 14.—Is decidedly better; has been able to sleep without an opiate, which she has been previously in the habit of using; returns home tomorrow, feeling quite able to undertake a journey. Rep. med.

Nov. 22.—Bore the journey very well, and has driven out twice since; her nervous state (until within the last two days) "decidedly better;" the catamenial period is at hand, and there is much irritability of head, and painful sensation in the lower part of the abdomen; the discharge still continues, but is nearly colorless; the supporter "most certainly relieves;" bowels irregular.

℞ Extr. lactucæ; extr. lupuli, camphoræ aa. ℈ i. M ft. pil. xij., sumat ij. h.s. et. Rep. p.r.n. Pulv. rhei c. magnesia primo mane si opus sit. Rep. mist.

Dec. 20.—Does not report favourably either as regards her increase of strength or diminution of irritability,—the unusually warm, moist weather may possibly have had some influence in this respect. Has taken the last prescribed pills, but does not mention that she derives any benefit from them. Complains of a "tender, hot pain in the lowest part of the back, and also at the back of the head, which stimulants and meat diet greatly increase." Her medical attendant has just prescribed a liniment of belladonna, opium, and soap, and is giving her steel in minute doses.

I have quoted this case as one of retroversion caused by great relaxation of the soft parts shortly after labour, and aided in no inconsiderable degree by the weight of the still relaxed uterus. The glazed tongue and mucous irritation of the intestinal canal, contributed not a little to keep up her state of emaciation and general debility, and I was unwilling to use the prone position, fearing that she could not bear it, although I now regret that slight trial of it was not made before having recourse to the supporter, for experience has since repeatedly proved to me, that we may not only rectify a retroverted uterus by this simple means, but (where there is much want of tone) even produce an opposite state of displacement, viz., anteversion. The supporter was applied with great care, and was worn without discomfort; indeed, in her report of herself after leaving town, she acknowledged that it certainly relieved her. The restoration of her health and strength went on very slowly, and she continued to suffer from the moral and physical irritability of her anæmic condition. In the course of a few weeks afterwards, she was induced to have the instrument removed, and put herself into other hands.

S. W., aged 29, married nine years, two children, three abortions between the intervals of child-bearing.

October 10, 1844.—Complains of forcing and and bearing down pains about the rectum, and of pain darting from the back towards the front of the pelvis; very much increased by the passage of fæces.

Examination per Vaginam.—Os uteri low and somewhat forwards; the fundus is felt quite at the lower part of the hollow of the sacrum. On attempting to pass the uterine sound, the os internum was found too contracted to allow it to pass. Some delay occurred from the occurrence of the catamenia. The os internum was then dilated, and the sound passed backwards into the tumour, which occupied the lower part of the hollow of the sacrum. The fundus was raised into its natural position, and Professor Simpson's uterine supporter applied without difficulty. A sanguineous discharge followed for a few hours, but she experienced an immediate relief to all her local symptoms. No further inconvenience was produced by the presence of the supporter; she improved rapidly in health and looks, remained in the hospital six days, and then returned home greatly improved, and has continued perfectly well up to the present time (Nov. 19).

Nov. 26.—Complains of rheumatic pains in the right leg; there is no irritation from the instrument; there is pain on emptying the rectum, but the bowels are confined. Pil. hydr. c. coloc. gr. x. h. s. Sodæ potassio-tartratis, ʒiss. primo mane.

Dec. 10.—The supporter was removed to-day; she has continued free from pain, except when the bowels are being relieved.

January 7, 1845.—Bowels rather confined, but quite free from her old pains.

March 17, 1847.—In the eighth month of pregnancy; complains much of soreness and pain of the left side; bowels confined. Pil. hydrarg. gr. v., alternis noctibus sumenda; haust. rhei. c. magnesia, primo mane.

April 7.—Feels quite well; has completed the eighth month of pregnancy.

This case, as its date shows, was one of the earliest where the true features of retroversion were thoroughly recognized, and although the first part of the report presents only a general sketch of it, yet the description affords a fair specimen of the diagnostic marks of retroversion. The pain in the lower part of the sacrum, aggravated occasionally to a sense of forcing and bearing down, and extending across the pelvis in the direction of the antero-posterior diameter, are well-marked symptoms of this displacement. They not only afford strong reasons for suspecting the nature of the complaint, but also indicate the degree to which the retroversion has extended, viz., that the uterus is lying across the pelvis nearly in a horizontal direction, a circumstance which is still further confirmed by the aggravation of pain during evacuation of the rectum. In many cases, when the fundus uteri is forced thus deeply down into the recto-vaginal pouch, it becomes much congested, and sometimes acutely tender. I mention this circumstance, in order to point out an error which it can easily lead an incautious observer into. On touching the os uteri with the finger, the patient will frequently start with pain, as in an ordinary case of inflammation of the cervix; and if this be also attended with painful defæcation, and pain on sitting down upon a hard seat, the deception will be complete. It is only by passing the finger *behind* the os and cervix uteri, so as to feel the retroverted fundus, that we can detect the true locality of the tenderness, viz., the fundus itself. Any pressure of the finger upon the cervix *in front* pushes it directly against the fundus, which is immediately behind, and therefore produces pain, not in the os or cervix, but in the congested fundus, as may be easily proved by pressing on the cervix from behind, when we shall find that the patient does not complain. The relief produced by Professor Simpson's uterine supporter was very complete, except, perhaps, a certain amount of pain about the rectum, probably from the long-continued pressure which it had suffered from the rectum. The interval which had elapsed between the removal of the instrument and her becoming pregnant showed that the good effects of the support which had thus been given to the uterus were permanent, and the occurrence of pregnancy was of itself a satisfactory proof that the uterus had not suffered from it.

HOSPITAL REPORTS.

WESTMINSTER HOSPITAL.

Communicated by GEORGE DOWNE, Esq.

STONE IN THE BLADDER.—LITHOTOMY.—RECOVERY.

John Gafley, aged 6 years, an apparently healthy little Irish boy, presented himself among the out-patients of the Hospital, having had symptoms of stone of three months' duration. He complained of great pain after micturition, chiefly referred to the end of the penis; bloody urine, and an inability to empty his bladder without occasionally altering his position. A small sound was introduced by Mr. Holt, and as careful an examination made as the cries and struggles of the patient would permit, without, however, any foreign body being detected. He was, therefore, desired to come again at the expiration of three days; be kept quiet, and have a mild purgative administered every night. The second examination was alike futile, and it was only upon a third trial, after a week's quietude, that

the stone was detected. He was consequently admitted an in-patient.

April 14.—Having been for some days kept upon spare diet, and the bowels moderately acted upon by the occasional administration of castor oil, it was decided the operation of lithotomy be performed. Chloroform was inhaled (in this instance acting very imperfectly, producing considerable convulsive action, accompanied by vomiting and expulsion of fæces, although the rectum had been previously emptied in the morning), when Mr. Holt pushed a common scalpel through the integument, in the direction of the neck of the bladder, and with a gentle sawing motion carried the incision the necessary length downwards and outwards; the groove in the staff was then felt for, and quickly detected, the point of the scalpel introduced and pressed gently forwards. An opening being made in the left lobe of the prostate, large enough to admit the point of the left forefinger, which followed the scalpel and dilated the wound sufficiently to allow its introduction into the bladder, the stone was immediately detected, and the staff withdrawn. The forceps were now had recourse to, and the stone removed, which proved to be a moderate-sized calculus, of compound structure. A piece of previously oiled lint was placed in the opening, and the patient sent to bed.

15th.—Passed a quiet night, having slept soundly. A large quantity of water was made both by the wound and urethra. No heat of skin or acceleration of pulse. Tongue clean and moist. Low diet.

16th.—But little urine having escaped by the wound, and the boy being somewhat restless, the lint was removed, when a quantity of water escaped with marked relief.

19th.—Has been progressing in the most favourable manner up to the present time, when Mr. Holt detected, contrary to his express directions, that one of the patients had yesterday given him a hearty meal of meat and potatoes. He has, consequently, great heat of skin; pulse 110. Restlessness; cheeks flushed. Pain in the head and region of the stomach. Has vomited a quantity of grumous matter, mixed with bile. When spoken to he is irritable, and answers snappishly. He was ordered one grain of calomel, one of ipecacuanha powder, and three of rhubarb, every four hours, until the bowels had been freely relieved.

20th.—Bowels have been open four times, and he is somewhat better. The pain is meliorated, but he has again vomited matter of a bilious character. The pulse is 100, and the skin less hot.

May 10th.—Up to the present time he has been suffering from infantile remittent fever, but is now considerably improved; he is daily carried to the top of the hospital; the wound has almost healed, and the urine escapes by the natural channel.

20th.—Left the hospital cured.

Remarks.—Mr. Holt remarked that this case afforded an excellent illustration of the evil consequences resulting from the administration of food at an injudicious moment. He believed the protracted recovery of the case was entirely dependent on the administration of food at a period when the stomach was unable to bear it, and where the large quantity taken acted as a most powerful irritant; the secretions, which were previously maintained with regularity, were now excessively deranged, and the boy's life placed in considerable jeopardy; the heart's action, from the sudden introduction of a quantity of new matter into the circulation, was accelerated; the liver stimulated to the utmost extent; and the general effects on the system at large made apparent by restlessness and subsequent wandering delirium; the wound, which had previously presented a healthy appearance, was now covered with a sanious discharge, and the urine loaded with phosphatic deposit.

LACERATED WOUND OF ARM—AMPUTATION—RECOVERY.

James Smith, aged 32, an engineer, was admitted April 10th, with compound fracture of the wrists. He states that, while oiling a portion of the machinery in one of the Richmond boats, his hand became entangled between the piston and the beam; upon examination, a large wound was discovered in the palm of the hand, extending beyond the radio-carpal articulation: the nerves, vessels, tendons, and cartilages of the carpal bones were exposed, the extremity of the radius comminuted, and considerable hæmorrhage had taken place. Mr. Holt decided upon immediately removing the arm above the seat of injury. He was placed under the influence of chloroform, when amputation, by anterior and posterior flaps, was performed; some little hæmorrhage occurred from the interosseous artery, which was secured by passing a common tenaculum through the vessel above where it had been divided, and tying it.—Assalcni's forceps not answering the purpose. The edges were approximated and retained by three sutures, strapping, and wet lint being applied over the stump. To have forty drops of tincture of opium.

11th.—Passed a quiet night, sleeping at intervals; pulse 80, and feeble; tongue moist; skin cool; bowels not open for the last two days. Take haust. cathart., beef-tea, and half a pint of porter.

12th.—Bowels twice relieved. Some pain being experienced, the arm was examined, and a little erysipelatous blush detected; the sutures were removed, and a bread poultice ordered to the wound. Skin hot; pulse 100, and feeble; tongue white. Mr. Holt desired he might take of liquor ammon. acet. one ounce, sesqui-carbonate of ammonia fifteen grains, tincture of card. two drachms, and water six ounces,—one ounce every four hours. Continue beef-tea and one pint of porter.

14th.—Improved; erysipelas somewhat subsided; tongue moist, and less white; skin cool; bowels freely open; pulse 90. Continue.

16th.—Suppuration of a healthy character is established, and he is progressing favourably.

May 1st.—A slight collection of matter having been detected at the upper and inner portion of the arm, an incision was made, when about an ounce of healthy pus escaped; in other respects is going on well.

23rd.—Since last report has been progressing favourably, and to-day left the Hospital cured.

ST. VINCENT'S HOSPITAL.

(From our Dublin Correspondent.)

In my last communication I mentioned, that Dr. O'Ferrall had been induced to conclude that the progress of rheumatic fever led to a gradual diminution of the blood globules, requiring, in time, the exhibition of antichlorotic remedies for their renewal. It seemed to me that this is a matter of so much importance, in connexion with practical medicine, that I have thought it proper to examine particularly into the grounds for Dr. O'Ferrall's conclusion, so as to ascertain whether it was founded upon data sufficiently fixed to entitle it to be received as an established truth in medical science. By the kindness of Dr. O'Ferrall, I have been furnished with the following cases from the records of the hospital, which, to my mind, abundantly confirm the chief points enumerated in my former report.

The first case shows, that a cardiac bruit may persist after the cure of rheumatic fever, although from its subsidence, after a certain period, there is reason to conclude that no permanent organic lesion had been established.

RHEUMATIC FEVER.—ENDO-PERICARDITIS.

Frances Gaffney, aged 20, a dressmaker, had been engaged at her trade during the previous six years. Soon after the commencement of her apprenticeship she began to suffer from pain in the left side, dyspnœa on exertion, and palpitations. Had, also, two attacks of fever during the same period, each of which lasted twenty-one days before crisis. On the 11th of May, 1843, she incurred rheumatic fever, with pain and swelling in feet, elbows, and shoulders, their severity being in the order recited. She applied to a medical man, who discovered that she had pericarditis, for which he bled her; and, on the 18th of May, she was admitted into St. Vincent's Hospital.

On examination she was perceived to be very nervous and hysterical; inclined to cry every instant; countenance flushed; its expression anxious and frightened. Tongue red, much thirst and anorexia. Pulse frequent and hard; skin hot and dry. There was some headache above temples. A little cough, but no *signs* referrible to the lungs. Wrists and ankle-joints swollen and painful; pains across shoulders. Dr. O'Ferrall detected frottement at the base of heart. There was also a distinct *echo soufflet* to be heard nearer to base than apex of heart. She was ordered leeches to the cardiac region, and put on calomel and opium.

On the 19th there was no change; but, on the 20th, it is noted, that the anxiety of countenance appeared increased; the face flushed; eyes suffused; bruit very distinct; but frottement no longer audible. Head shaved and temples leeched; calomel and opium continued; and camphorated mercurial ointment rubbed to abdomen.

The gums became a little tender on the 22nd. The countenance did not appear so anxious or flushed. Bruit continued. The next day the mouth became very sore, and the mercury was stopped. The face was pallid and swollen; there was copious salivary discharge. The bruit still continued. On the 24th there was some mercurial tenesmus and diarrhœa, with colicky pains. The swelling and pains in joints were nearly gone. She was ordered anodyne enemata, which removed the entire symptoms, and on the 26th, it is reported, that the cardiac bruit was scarcely perceptible. On the 27th, all evidence of arthritis and cardiac disease had disappeared; the mouth continued swoollen and hot; but this was relieved by leeching the cheeks, and applying lunar caustic solution to the white patches on buccal mucous membrane. From the 27th to the 29th no cardiac bruit could be detected; she appeared pale and weak; but the only remains of the rheumatism consisted in slight pains about the shoulders. On the latter date, however, a distinct bruit became audible at the base of heart behind sternum. Notwithstanding the recurrence of this cardiac phenomenon, her appearance so manifestly demanded tonics and nourishment, that she was ordered wine and meat, and prescribed quinine. Under this treatment she perfectly recovered; the cardiac bruit disappeared, and she left the Hospital in perfect health.

The next case is one of very great importance, and I shall let it speak for itself.

ACUTE RHEUMATISM, ENDO-PERICARDITIS, DRY PLEURISY, BRONCHITIS, PULMONARY APOPLEXY, AUTOPSY.

Catherine Sawlor, aged 9, was admitted into St. Vincent's Hospital, February 13th, 1843. She had been seized with rheumatism the week of the previous Christmas, and at the time she entered Hospital the pains and tenderness of joints still persisted. Her countenance was turgid and swollen, her breathing very much oppressed, and moist and dry bronchial râles generally diffused over both. She complained of a stitch catching breath in lower part of right side, and in the same place frottement accompanying respiratory movements could be detected. There was also frottement in the region of the heart, increased præcordial dullness, and souffiet accompanying both sounds. There was no difficulty in diagnosing dry pleurisy and endo-pericarditis, general bronchitis, and subsiding arthritis. She was ordered a large dose of calomel combined with opium, to be followed by divided doses of mercury with chalk and Dover's powder. Leeches were applied to the region of the heart, and, subsequently, the same part was blistered. Under this treatment the bronchitic râles diminished; the breathing became less laborious; the fever less turgid; the stitch in side ceased; the bruit in second sound behind sternum grew indistinct; but, it is reported, that, on the 26th, the cardiac frottement had become a loud leather creak, very audible at base; and that the bruit in first sound below nipple was very distinct and rough. From this date the child continued to improve to the 10th of March. The leather creak had then disappeared; the cough and dyspnœa had so far abated that she appeared to lie without distress;

the pains in joints had gone; but as a bruit in the first sound at the base of heart still continued and, as the mercury appeared to produce no unpleasant effects, it was thought advisable to continue its administration. On the 12th, however a marked change for the worse took place. Dr. O'Ferrall made on this day the following note:—"She is labouring under great dyspnœa, increased by lying on left side; skin hot, lips florid, alæ dilating; complains of a pain in head that makes her cry. Percussion on both sides below scapula tympanitic; respiration puerile; expiration inaudible; some roughness in the inspiration on the left side; a few mucous râles in front; none posteriorly." Leeches were applied to forehead; and she was ordered two grains of calomel, to be followed by a dose of castor oil; after this she again went on with the mercury with chalk until the 21st, when anasarca commenced in the extremities. She was now ordered diuretics, but continued without any manifestation of improvement until the 30th. There was now perceived some streaks of blood in the sputa, and a comparative dulness was detected in the right side posteriorly in which part there was, also, a minute crepitus From this time the bronchitic râles becames so loud as to obscure the sounds of heart; the pulse grew fuller, the anasarca increased, and the dyspnœa became extreme. She died on the 6th of April.

At the autopsy, the right pleura was found to contain two or three pints of transparent serum This hydrothorax evidently occurred during the last agony, for there was no evidence of it the day before death. The lower lobe of the right lung was black, solid, and, in appearance, similar to spleen. The heart was somewhat enlarged, but the left ventricle continued to form the apex. The pericardium contained a very little serum, but not a trace of lymph or false membrane was on its serous surface, which was smooth and polished. The mitral and aortic valves appeared perfectly normal except some few minute vegetations upon the free margins.

From this case it is manifest, that a severe endopericarditis may be completely cured, and yet the patient may die of the consequences of those diseases. There was here no obstruction to the circulation to produce the pulmonary apoplexy or anasarca. At the time that obstruction existed these effusions did not take place; and it was not until after the heart disease was removed, that dropsy and extravasation supervened. Together with these, super-secretion took place from the bronchial mucous membrane which ended in asphyxia. Just as it is impossible to ascribe the dropsy or pulmonary apoplexy to obstruction, so this last and fatal catarrh cannot be attributed to inflammation. Its genesis was accompanied by increasing feebleness of pulse. The child was getting better until the 10th of March; from that time it gradually sunk; catarrh, dropsy, and pulmonary apoplexy successively came on. Might a more decidedly tonic and nourishing treatment, immediately upon the full action of the mercury, have been attended by a different result? This question was asked at the time, and subsequent experience authorized an answer in the affirmative.

ACUTE RHEUMATISM—CARDITIS FOLLOWED BY ANÆMIA. CHALYBEATES—CURE.

Mary McDermott, aged 26, married, the mother of two children, of a nervous, irritable constitution. Had metritis after her last confinement (eight months previously), and subsequently was subject to diarrhœa, ending in dysentery during five months; she became exceedingly weak, and thinking they would strengthen, she took some excursions into the country during severe weather. The consequence was an attack of rheumatism, which confined her for three weeks; but during this attack she did not present any cardiac symptoms. This was three months before her admission into St. Vincent's Hospital, which she entered on the 25th of February, 1843, for a second attack of rheumatism, which commenced ten days before. Upon admission, the arthritic pains, swellings, and tenderness were fast subsiding; she had slight subacute gastritis; a little cough, but no other pulmonary symptoms. The pulse was strong and hard there was a soufflet in first sound under nipple, with increased action of vessels of the neck with fremissement. The heart was leeched, and she was ordered calomel and opium. On the 1st of March, Dr. O'Ferrall could still detect the bruit in first sound; the calomel was beginning to affect the bowels, and was accordingly replaced by mercury with chalk. On the 2nd a bruit musical was detected in the vessels of the neck, the cardiac bruit continuing. As the bruit do dible persisted she was ordered on the 13th an ounce of Bewley's aqua chalybeata three times a-day. Her catamenia came on the 23rd; and she continued to progress favourably until her dismission on the 10th of April. There is a note to the effect, that she has come sometimes since to the Dispensary attached to the Hospital, complaining of toothache, &c., but quite well of the heart affection, and without a trace of abnormal bruit.

This patient was naturally delicate, had suffered from prolonged sickness, and it did not appear unlikely that a chlorotic condition had been induced by the leeching and mercury employed in her treatment. From that period, however, Dr. O'Ferrall kept a sharp look out after the condition of the cervical vessels in cases of rheumatism and ascertained that a bruit musicale was a very common accompaniment of the latter stages of the disease.

A considerable number of cases might be brought forward in proof of this proposition; the following will serve as examples:—

RHEUMATIC FEVER TREATED BY COLCHICUM AND BARK—SUBSEQUENT ANÆMIA. CHALYBEATES.

Catherine McCormick, admitted January 13th 1848. This girl came into hospital with pain and swelling of several joints; had no heart affection She was given tincture of the seeds of colchicum in scruple doses three times a day, as long as the pains continued severe, and the urine deposited lithates. When the pains moderated, and the urine became abundant, she was put on Donovan's syrup of bark, under the use of which the rheumatism disappeared; but, while taking this remedy a bruit became audible in the first sound of heart behind sternum; and, at the same time, a bruit musical established itself in the vessels of the neck. These signs were regarded as of anæmic origin, and on that supposition treated successfully by chalybeates

Another and similar case occurred in the instance of Catherine Higgins, admitted on the 26th of March, 1849. I mention this case, because in it it was necessary to return to the use of the colchicum, after the patient had been for some time taking bark. The indications for doing so were, the return of the pains and re-appearance of lithates in the urine. In this case, also, anæmic bruits towards the decline of the disease, pointed out the diminution of hæmatosyne, and indicated the propriety of exhibiting chalybeates. In neither of these cases was there any antiphlogistic or weakening treatment employed, to which the subsequent anæmia could be attributed. In both, the diminution of the blood globules appeared to be an essential consequence of the previous disease. I, therefore, think we are entitled to decide that Dr. O'Ferrall's conclusion is fully warranted by experience, and that he has made a very valuable contribution to practical medicine.

ABSCESS SIMULATING MALIGNANT DISEASE.

A remarkable case of this nature lately occurred at St. Vincent's Hospital. The patient, an old woman of about 60, having a sallow unhealthy aspect, was admitted on account of a large tumour, extending over the two lower thirds of thigh. Upon being handled this tumour was found to be variable in consistence, the greater part of it being elastic, but in some places being hard and resisting. A firm nob was felt projecting in the popliteal spaces. Some large veins ramified on the surface of the tumour. The leg was considerably shorter than the opposite one. Upon inquiring into her history, it appeared that she had hurt her knee when a young girl by a fall on some stone steps, and that ever since she had been subject to occasional attacks of pain and swelling; but the commencement of the present disease she ascribed to the beginning of March in the present year. She then first perceived pain and enlargement of the lower part of thigh, and since that time these symptoms have gone on increasing until the disease attained its present volume.

Upon a careful examination of the swelling, Dr. O'Ferrall satisfied himself that the elastic part contained a depôt full of liquid. He was principally guided in arriving at this conclusion by the depth to which he could, by a gradual effort, press his finger, and the sudden resistance to this pressure which occurred at the greatest depth. The presence of liquid being decided, the probability was that it was pus. The hard parts had now to be accounted for; but by a careful examination of their form and relations he soon ascertained that they were caused by the displacement of the normal bones; one of these being the patella, pushed outwards and upwards; two others, at the lower part of the sides of the tumour, being the condyles; and the hard prominence in the popliteal space, caused by the presence there of the head of the tibia, dislocated backwards.

Dr. O'Ferrall having explained the grounds upon which he formed the foregoing diagnosis, to the class, proceeded to make a puncture with a grooved needle; a small quantity of pus issued, showing the correctness of the views formed; upon this, a larger opening was made with a bistoury; a pint and a-half of strumous pus escaped, when the opening became closed by a curdy mass, and as there was no object to be gained by permitting further escape, the pain and tension being already relieved, advantage was taken of this accident to prevent the ingress of air, about two or three pints being still retained in the abscess; a large poultice was then applied. Since the evacuation of the abscess, the patient has much improved in general health.

PROGRESS OF MEDICAL SCIENCE.

FRANCE.

CHOLERA.

The cholera has nearly disappeared from Paris, and altogether so from its environs; yet Parthian-like, its last blows are treacherous and fatal. Several Medical men, connected with the military hospitals, have been cut off within the last two weeks. The total mortality in Paris, since the commencement, now amounts to 18,739,—a number considerably over that of 1832. The accounts from the provinces are still very unfavourable. The ravages of the epidemic are great in all the chief cities of the south, Lyons, Marseilles, Toulon, &c. In the west, Strasburg also suffers severely.

The question of contagion again came before the notice of the Academy of Medicine on Monday last, but like all other debatable points, it seems to become more obscure each time that it is submitted to medical discussion. M. Begin, a surgeon attached to the military hospital of Arras, mentioned some facts not devoid of interest. 350 men were dismissed from one of the barracks in which the epidemic had broken out with excessive violence. A great many of the men laboured under premonitory diarrhœa, at the time of their being thus distributed in the other quarters of the town. They mixed with 2,000 of their comrades, and not only did not communicate the disease to the latter, but seemed to have escaped from the focus of infection, for only three of them died. In opposition to this fact, however, many medical men related examples where it was very difficult indeed not to see the influence of some contagious principle.

At the same meeting a vast number of applications were made by persons who think themselves entitled to the prize of 100,000 francs left by the Hamburg banker, to any one that may discover a specific for cholera. According to these worthies, there is no lack of "infallibles" already. We shall, probably, soon have a reinforcement from the hand of quacks.

At the last meeting of the Society of Biology, M.

Sequard mentioned a very curious case of true tubercle developed in the cervical portion of the spinal marrow of a rabbit. What renders this case interesting is, that the symptoms were almost exactly the same as they would have been, had the subject been of the human species—trembling and contracture, followed by paralysis, with throwing back of the head, &c., &c.

SYPHILITIC CONTRACTION OF THE LARYNX.

At a meeting of the Surgical Society, on the 12th, M. Ricord showed two patients affected with this rare disease. The first was a young man, who had laboured for some time under tertiary syphilis. The larynx was attacked at last, and the patient appeared threatened with asphyxia. M. Ricord thought it necessary to perform tracheotomy; but, on dividing the trachea, the air did not gain access to the lungs, and there was nearly complete asphyxia. M. Ricord himself and the assistants, in a state of indescribable anxiety, expected to see the patient perish every moment under the knife. The presence of mind of M. Ricord saved him. After a slight hesitation, he applied his mouth to the bleeding wound, and, by strong efforts of suction, succeeded in removing some of the pus, mucus, and blood, that obstructed the passage. He then inflated the lungs with all his might, and, at the same time, compressing or raising the chest, he succeeded in re-establishing the respiratory movements after five or six minutes. During a whole month it was almost impossible to apply a canula or any other kind of instrument, small or curved. The difficulties, however, were overcome at length, and the canula of M. Berrard introduced. The patient will probably be forced to continue it for the rest of his life, because the syphilitic tumours which obstruct the trachea, tend constantly by their growth to obliterate the artificial opening.

After the relation of this case, M. Ricord was warmly congratulated by many of his colleagues for his promptness of decision, which prevented an accident of the most deplorable kind. When a patient dies under the knife, the surgeon is always the guilty party in the eyes of the public.

SCOTLAND.

[From our Edinburgh Correspondent.]

Some weeks ago it was announced that a vacancy had been declared among the surgeons of the Edinburgh Infirmary, and the names of the candidates who first appeared were noticed in the *Medical Times*. Since then Mr. Spence, who has been well known for a considerable time in Edinburgh as a Teacher of Anatomy, and more recently as a rising operator, came forward as a candidate. It was also mentioned in a former communication that Professor Miller, the expiration of whose term of service created the vacancy, had applied to be re-appointed as acting surgeon, so that, in the event of his request being granted, the new applications would be superseded. Till Mr. Spence appeared among the candidates, it was commonly supposed that Professor Miller would succeed in his object. But as Mr. Spence came forward with a surgical reputation in his favour, it became a question whether the interests of the Infirmary would be better served in the end by retaining Professor Miller or by placing Mr. Spence on the establishment; and, as usual, different views were taken by different parties. On Monday last the managers of the Infirmary settled the question in favour of Mr. Miller, by re-appointing him Senior Acting Surgeon for another year. In this re-appointment the managers have done nothing more than their rules warrant; for though the general bearing of the regulation is, that a surgeon's whole period of service shall expire at the end of eight years, yet there is a proviso added, that it may be extended if the managers see fit. It may be doubted, however, if it would be wise in the managers to encourage applications to this effect from the surgeons concerned. When an application is made, backed by a surgeon's friends, it is not easy to resist importunity, even though the interests of the Institution may counsel a different course. It would plainly be a good rule, that the extension of a surgeon's term of service beyond the statutory period should be the unsolicited act of the Board of Management, as flowing from a conviction that his particular merits deserved such a mark of their approbation.

In the present case, though there may still be differences of opinion, it cannot be said that the Managers have gone far wrong, inasmuch as they have retained in the hospital a surgeon of deservedly high reputation. If they have done wrong at all, it is in not putting his re-election solely on the footing of a reward for his particular merits in the previous term of his service. But there is even claimed for them the praise of having acted a very disinterested part in re-appointing Mr. Miller at the very moment when a rumour, apparently well founded, first got abroad, that the Medical Faculty of the University, of which, as Professor of Surgery he is one, are about to spring a mine on them by setting up a New Hospital. If such a scheme be carried out, it will diminish the income of the Royal Infirmary, as well by dividing the contributions of the public of Edinburgh, as by withdrawing a large proportion of the pupils. And when the authoritative evidence in favour of the existence of this still unannounced intention was considered, it could not have seemed a very far-seeing determination on the part of the Managers to begin the rearing of surgeons fit to attract pupils in the event of the new scheme depriving them of those who at present support the surgical reputation of the Infirmary.

Of the scheme itself of a new hospital, we can hardly venture to speak at present. It is very certain the Medical Faculty of the University have all the inclination in the world to found such an hospital. They wish to convict the Infirmary Managers of antiquated prejudices. They are eager to exemplify the maxim, that the most strictly clinical basis of management is the truest humanity. But everybody asks where the funds are to be had. Can General Reid's Musical Bequest to the University be made to play the part of Amphion's harp, when at raised the walls of Thebes? There is, to be sure, a considerable sum at the disposal of the Edinburgh bar, left some time back by an Edinburgh tradesman of the name of Chalmers, to erect an hospital "for the Sick and Hurt." But, if their hopes at present have no other foundation to build on than the Chalmer's Fund, many of us have a shrewd guess that, though they may get a new hospital, they will find the Advocate-Managers harder task masters than the much-abused Managers of the Old House.

Two new lecturers on surgery appear in the Edinburgh Extra-Academical School next winter,—Dr. Mackenzie, whose intention was mentioned in a former communication, and Mr. Spence, whose application for the assistantship in the Infirmary was superseded by Mr. Miller's re-appointment. He was formerly associated with Dr. Lonsdale, now of Carlisle, and Dr. Handyside, in their course of Anatomy, but for a few years past he has taken no part in teaching.

The Public Health.—All hail to Government care of the public health wheresoever we find it! Would that our own Board of Health would take a leaf from the book of other nations, and endeavour to release our capital and the chief cities of our country from the hygienic curse that rests upon them! The Government of Piedmont has lately promulgated—and that notwithstanding their political embarrassments—instructions to local authorities regarding the public health in their several districts. Hospitals, prisons, and penitentiaries are to be regularly inspected, and the regulations concerning their hygienic relations peremptorily enforced; apothecaries' shops are to be examined as regards the purity and sufficiency of their drugs; grocers, confectioners, dealers in spirits, beer, vinegar, and gaseous waters are to submit the purity of their wares to the consideration and sanction of the Board; and the keepers of baths and the manufacturers of artificial mineral waters are likewise to obtain their license for the exercise of their craft.

Correspondents are requested to address their Communications to "The Editor of the Medical Times *147, Strand."*

THE MEDICAL TIMES.

SATURDAY, OCTOBER 6, 1849.

The last few months will constitute an era in the history of this great Metropolis, in consequence of the mortality which has resulted from the invasion of Cholera. Since the 17th century no Epidemic has been so fatal, for upwards of 13,000 persons have been already cut down in a few weeks by this modern plague. Medicine, in a large number of cases, appears to have been powerless; and thus the science of the Physician, in measuring strength with the enemy, has been placed *hors de combat*.

The history of Epidemic Cholera has been clearly traced; and though a wide and remarkable difference exists between it and previous Epidemics, yet its eccentric progress has been marked with an accuracy as complete as any in the archives of Medicine. That there is some subtile agent which produces this disease admits of no doubt, but science has been unable yet to discover what the virus is. There are certain conditions, however, which favour its development and diffusion, and we have on this subject an accumulation of facts highly instructive.

The Surgeons of India were not slow in discovering that Cholera visited more frequently and more fatally, low, confined, and marshy places; and Medical men in Europe and America have also remarked that the localities of great cities, whose sanitary condition has been grossly neglected, are attacked with the greatest severity. It was a knowledge of this fact which gave a new impulse to the Sanitary Reform question; and, before the present Epidemic reached our shores, men who had made themselves acquainted with the condition of our towns and villages, forewarned the people of their danger, and exhorted the Government to interpose for their safety. Three sanitary Bills were at different times introduced into the House of Commons, but were ignored through the opposition of persons whose vested interests were threatened; and it was not till Cholera was at our doors, that Parliamentary Acts were passed for the improvement of the health of towns. These new laws invested the Board of Health with certain powers. It was supposed that the authority with which it was thus clothed

would have been promptly and vigorously used in putting down "nuisances" which experience had proved favoured the development of some most malignant diseases. But, as we have before stated, Cholera has appeared in this great city; it has visited the very localties which it was expected it would; it has slain its 13,000 victims, and even now the destroying angel has not put up his sword;—in the midst of this havock, we look around to see what has been done in the way of sanitary reform, and we are astonished to find that hardly an improvement of any importance has been effected.

In the sewered streets, almost a countless number of untrapped gully-holes afford a free egress to the foul effluvia generated by the Lethean stream which rolls below; and the Commissioners of Westminster have adopted the notable expedient of driving those gases with ten-fold force into the streets under their jurisdiction, by closing with an elastic shutter, which rises and falls with the level of the water, the mouth of the great sewer debouching into the Thames near Vauxhall-bridge. The atmosphere of Belgravia has, in consequence, become especially offensive; and in the third and fourth-rate streets, cholera and typhus have been carrying off numerous victims.

In every district, moreover, we find many of the habitations of the poor without any effective drainage. In some streets with which we are acquainted, and in which Cholera has raged with great violence, not a single effort has been made to render the dwellings more fit for human beings. The landlords laugh to scorn the remonstrances of sanitary officers and medical men; and those who have the power to punish the refractory owners of houses appear indisposed to exercise it. So long as the present system of lodging the poor prevails, disease and immorality will be rife amongst them; and if their wrongs are not now redressed, the day is not far distant when the Legislature will be compelled to interpose in their behalf.

The manufactories of soap-boilers, tallow-melters, glue-makers, and bone-burners, are in as active operation as ever, and from their several establishments the same offensive effluvia are emitted as before the visitation of the Cholera. Smithfield still remains, with all its ancient privileges, intact; and vested interests are permitted to triumph over the claims of humanity. True, there is a report that the nuisance is to be removed; but how many lives will be sacrificed, before the Legislature interpose to free the city of one of its most fertile sources of disease? In Aldersgate-street, the filthy laystall still exists, to which we adverted on a former occasion; and it is only at the eleventh hour that the Board of Health has begun to check the system of intramural interments. If those sapient citizens, who seem so attached to these abominations, would only attend to their natural instinct—should this not have become deadened by repetition—they would find an unanswerable argument for their removal, in the difficulty of appeasing the annoyance experienced by their olfactory organs whilst passing these places.

From the sources referred to arise *invisible* agents productive of disease and death; but to these must be added one, cognizable to the *sight*,—the Smoke Nuisance. The inhabitants of this Metropolis are compelled to breathe an atmosphere impregnated with carbon, which impedes the healthy action of the lungs, and therefore, by weakening the natural powers of life, renders an individual more susceptible of disease. It is well known that there is often found a carbonaceous deposit on the surface of the membrane lining the bronchial tubes; an atmosphere vitiated by opaque smoke is calculated to increase this deposit. From an immense number of chimneys, and from the many steam-boats on the river, there are constantly poured forth volumes of dense black smoke, which hang like a pall over this devoted city. And yet the nuisance is capable of being, to a great extent, abated. It has been proved, by experiment, that, at little cost, a large proportion of the volatile products from coal may be consumed. The subject was brought before Parliament at the close of the last session, yet nothing was done; though it was stated before the House, that in Manchester, and some other towns, the experiment had been successfully carried out, and it would only have been required to enact that to each furnace the same preventive means should be applied.

Such is the state of London at the present moment, after all the efforts of sanitary reformers, and with a fatal Epidemic in our midst which, although abated, who shall say will not return with renewed vigour? How long, we ask, is such a state of things to continue? Are vested interests to triumph for ever over the claims of humanity? Is medical science to be left to cope, single-handed, with so many evils? If London is to continue a great and prosperous city, sanitary reform must be vigorously enforced. We are aware that it is a great work, but it *can* be accomplished. Let the Board of Health not lose a moment, but, as this is its province, put forth all its powers, and answer the end for which it was appointed.

DR. BRITTAN'S CHOLERA VIEWS.

DR. BRITTAN's observations on the microscopic elements of the sediment of the Cholera discharges, to which we referred in our last Number, have appeared in the *Medical Gazette*. We find we have anticipated almost every thing which Dr. Brittan has now published, and, after the best consideration we can bestow on the subject, we are disposed to think, that we said last week all that is at present to be said. It appears evident, that the value of such observations as those of Dr. Brittan, depends upon their completeness and their universality. At present, the description given of these "annular bodies" is [illegible]perfect, that we are really doubtful whether they can be considered of fungous origin. The supposed identity of these bodies, and of the organic spherules collected from the atmosphere, is based entirely on a presumed similarity in form; and repeated examinations are necessary, before we can even affirm the constancy of such form. Again, the value of the observations necessarily depends upon the proof which can be given of the universality of the phenomena; but, at present, perhaps not more than 100 examinations have been made of Cholera discharges, for the purpose of determining the presence of the "annular bodies," and these examinations have been made only in one or two localities. But to prove these fungi,—if they are fungi,—to be invariable elements of the Cholera discharges, and of the Cholera atmosphere, examinations must be made, not in hundreds, but in thousands of patients; not in two, but in hundreds of localities.

Even now grave doubts may be entertained as to the constant presence of these "annular bodies" in the Cholera discharges. They do not seem to have been distinguished from other cell-forms in the microscopic examinations which were made in the former epidemic by Boehm, or in those which have been published in the present attack by Parkes and Gairdner. It is quite possible, indeed, that these "annular bodies" may have been always overlooked; but, at this point of the inquiry, it may be doubted whether this was the case, or whether they were not really absent in the cases which fell under the notice of the observers above mentioned. Indeed, we find Dr. Brittan himself stating, that "in very rapidly fatal cases these bodies are sometimes to be met with only in very small quantity, *or are altogether absent*," although such cases are exactly those in which we should, *a priori*, expect to find the "annular bodies" in largest quantity, if they are to be admitted as the *cause* of cholera. We perceive also, in Mr. Swayne's Table, out of twenty-eight observations, one case noted as "unusually severe," in which none of the "annular bodies" were found; three other cases, in which they were also absent; and no less than fifteen in which they were few, and often doubtful and indistinct. We have no wish to throw unnecessary doubt on the existence of these bodies; still we cannot but consider that their universal presence is anything but proved, even by the observations of those gentlemen upon whose inquiries the existence of these bodies has been admitted.

In Dr. Budd's Letter, to which we alluded last week, we find the whole question summarily disposed of. No doubts, no reservations, no restrictions are admitted. The many gaps which direct observation has omitted, are dexterously filled in by the convenient materials of probability and conjecture. The fungous origin of cholera is at once assumed, the spread of the disease is thereby explained, and the method of prevention pointed out. And yet the only new fact, if it be a fact, which Dr. Budd can add to Dr. Brittan's observations, is the detection of these "annular bodies" in the water procured from Cholera districts. As far as we can gather from his Letter, this observation and Dr. Brittan's facts form the sum of the evidence on which the conclusions rest. But, allowing to Dr. Budd the utmost advantage he can derive from all the facts hitherto known, and permitting to these facts much greater precision and certainty than they are yet entitled to, let us ask Dr. Budd the following simple questions:—

1. Has he any other grounds for considering the "annular bodies" to be the *cause* of Cholera, except on the supposition which *cannot* yet be proved, that the presence of these bodies constantly coincides with the manifestation of the symptoms of Cholera?

2. Why, if the annular bodies are "disseminated in the air in the form of impalpable particles," are they taken into the system only by swallowing, and not by respiration?

3. Why, if they are fungi, should the "annular bodies" be "developed *only* in the human intestine?"

4. How is it established, that the "peculiar flux," with its consequences, constitutes the disease termed "Cholera," seeing that this is one of those important points on which a great difference of opinion exists, and which is certainly not to be hastily decided on the strength of a mere hypothesis?

We conceive that Dr. Budd will have some little difficulty in answering these queries with the evidence he at present possesses. But we will venture to ask him one more question. If it be at present a mere series of hypotheses,—1, that these annular bodies produce Cholera; 2, that they are received into the human system only by swallowing; 3, that water is their principal vehicle; 4, that they are propagated only in the human intestine: if all these assertions are supported by observations of the most limited kind, what would Dr. Budd say to a man who comes gravely forward to recommend to the Government preventive measures as a certain method of arresting the spread of Cholera, which are based solely on these hypothetical opinions? Dr. Budd proposes to destroy the supposed cause of Cholera by "receiving the discharges from the sick into some chemical fluid known to be fatal to beings of the fungus tribe." But, if the hypothesis be not true, and if the "annular bodies" are not the cause of Cholera, his method fails. If they *are* the cause, but are not disseminated only through the medium of drinking water, or of food, his method fails. If they are the cause, and *are* disseminated through the medium of drinking water or of food, but are not solely propagated in the human intestine, his method fails. A single deficiency in the hypothetical conclusions strikes away the base from the hypothetical treatment.

It is true, that Dr. Budd may be quite correct in his hypothesis and in his treatment. We should not the less strongly object to the "Royal road" by which he arrives at Truth. In the case of Cholera, as of all other sections of Medicine, observation, and not conjecture, should be the course of the Physician. The fungous theory of Cholera may be true; but it must be demonstrated, before we can admit it to be so. At present we are still very distant from such a conclusion.

THE RISE AND FALL OF GLYCERINE.

The immortal dramatist has said, there are

> Tongues in trees, books in the running brooks,
> Sermons in stones, and good in everything.

It is amusing, and at the same time painful, to witness the stately and pompous manner in which imagined new discoveries are announced. Nor is it uninstructive to contemplate the mode in which they are introduced to public notice. Paragraph after paragraph finds its way into non-professional Journals, relating the wonderful success of the new remedy in the hands of Mr. This or Dr. That. The blind see, as if touched by the charmed wand; the deaf hear, and look with astonishment on the professional magician. Crowds beset the door of the fortunate practitioner, and gather in the distance, breathless from anxiety at the promised relief. Not only are the means furnished for, but substantial inducements prompt to further publicity. The ball is kept in lively play; bandied from one publication to another, until the point of repletion is at length reached, and a character established for enterprise, ingenuity, and tact. Then it becomes no longer convenient to be known for any peculiar excellence in the treatment of any one disease, and the ball is allowed gently to drop.

If not this a true picture of the mode in which restless ambition sometimes mounts the ladder to temporary distinction or to notoriety? We do not find fault with those by whom the ascent is made—we leave them to the enjoyment of the feelings which such ascents never fail to inspire.

It is the public that is in fault, and, to some extent, the Medical Profession. The ignorance of the first may, in some degree, be calculated upon. It is natural they should swallow with avidity that which they do not understand. But what are we to think of the intellectual condition of too many of the Medical Profession? On their behalf, ignorance cannot be urged, except as a libel on their understanding, attainments, and position in society. And yet their frequent anxiety to receive, and implicitly to adopt, everything new that is advanced, however crude or improbable the influence it exerts may appear, presents no flattering picture. Had a little common sense been brought into play,—we will not allude to the necessity of any superior penetration,—would they so readily have believed that Glycerine had a wonderful power in restoring hearing? Suppose they had asked themselves,—and the question is not unimportant,—on what does deafness depend in the majority of instances? Surely if they had recollected the structural changes which constitute by far its most frequent cause, they could have arrived but at one conclusion:—that in the greater number of cases, no such remedy could possibly be of advantage—unless, indeed, the beautiful and complicated apparatus of hearing, bones, nerves, membranes, could be replaced and compensated by—a little fat! And if further they considered those cases which are characterised by functional derangement, their own experience would at once suggest various remedies in daily use and of unquestionable efficacy. Among these, Glycerine may be numbered; and that without risk of disturbance. It has had its day, and it has served its turn.

It is human nature to express regret on that which ceases to be, particularly when it has been held up to admiration, and endeared to us by no ordinary anticipations of its wonderful properties. Glycerine, however, is dead, and it will require far more talent to re-animate it, than was required to breathe into it the spirit of life.

There are "sermons in stones," and Glycerine would be a fertile text for a discourse on the mutability of human hopes,—on the inevitable law of decay and annihilation inherent in everything that is good,—on the weakness of poor human nature,—on its credulity, and on the want of just and enlarged philosophical views more generally pervading the Medical Profession. We will not sermonize, but simply suggest Glycerine as a text for the enlightened reader, and, perhaps, some one will favour us with well-digested thoughts on so important a subject. Not that we wish to bring it back to life in all its seducing and attractive promises. It will necessarily be delicate; and we cannot afford space, in the pages of the *Medical Times*, to re-establish it in its pristine vigour.

"There is good in everything." Glycerine is good, because it has a moral; and we doubt not, that those who have enriched themselves by the application of the remedy, are too well occupied to work out the reflections which the moral suggests.

On another occasion, we may endeavour to bring under notice some of the long forgotten *idols* of the Medical Profession; and, in search of them, we need not go beyond the recollections of the present generation. In contemplating the more remarkable of them, we have been struck with the facts, that the idol and its creator, the nurse and the introducer, have been short-lived in reputation, and that there is greater difficulty in recalling the name of the fortunate wight who flourished on the specific of his own happy and inspired thoughts, than in bringing to mind the once-renowned properties of the remedy. This is strange. It may arise from some peculiarity in our mental constitution; and if this be not the case, there is only one other mode of explaining the phenomenon. It would appear, that the talents of the individual were less calculated to leave an impression on the times in which he lived, than the remedy which he introduced. This is a painful reflection. Our great Surgeons and Physicians—men who have left a name to honour and respect—have never been specific doctors. They had no cure—all remedy—for the ear, the eye, the lungs, or for any other diseased organ; and the high-toned and high-minded course which they pursued, should be held up as an example to all who are ambitious to bequeath to posterity an imperishable record of their talents.

DR. JAMES ARNOTT'S TREATMENT OF CHOLERA.

We lately called on Dr. James Arnott to show cause why his single testimony should be deemed adequate to set aside certain long received maxims in the practice of medicine. Our readers have seen the answer made by Dr. Arnott to that appeal. We assured him that we were no more sceptical than the occasion demanded, and respectfully asked him to put us in a position to judge of the weight due to his testimony. We pointed out to him the qualifications which, since the days of Bacon, have been held requisite to the competency of a witness who speaks to wholly new phenomena at variance with older observations. Upon this, the Doctor thinks fit to charge us with want of dignity and with ungentleman-like conduct, and seems to feel himself freely entitled to make use of the *ipse dixit* as a conclusive proof. To nothing but the reiteration of this inanity will he condescend. We give him friendly counsel,

when we advise him to the sparing use of this pseudo-argument, which only sits naturally and becomingly on the lips of the all-impudent quack, and is the very talisman by which he fleeces the too-credulous public. Will Dr. Arnott permit us to remonstrate with him? We are sure we speak the sentiments of all the sensible part of the Medical Profession. Will he allow us to hold up the mirror to his real position, as respects his proposal of benumbing cold in Cholera?

Dr. Arnott, some time ago, saw reason to believe that benumbing cold is a useful remedy in headache, and he has since suggested the use of this agent in various diseases. While in July last he was writing a paper on the use of cold for the restraint of hæmorrhage after delivery, a sudden thought occurred to him, that "a mixture of snow and salt at the temperature of the zero of Fahrenheit is the only remedy of which the power appears commensurate with the violence of Cholera;" and, accordingly, he made the announcement of this inspiration in a postscript to the letter he was writing at the moment it rose on his mind. A fortnight later, he published some theoretical views tending, as he thought, to strengthen this idea. For the next two or three weeks, he was engaged in looking out for a case of Cholera, on which to test his inspiration. At last he met with the case of a boy, and soon after with that of an old man, in both of which he pronounced the attempted frigorific to be of good effect. In both cases other treatment was practised. In the case of the old man, the characteristic symptoms of Asiatic Cholera were not developed, and the case of the boy is not detailed with the minuteness requisite to convince us of its having been a genuine instance of Asiatic Cholera.

Let Dr. Arnott look at this picture, and say if the man who sat for it be fairly entitled to complain of being dealt with in what he styles an undignified and ungentlemanlike manner when he was reminded that it was possible his preconceived notions might have led him to attach a higher value to the effect of cold in cholera than the paucity of his observations warranted. Is this a time to ask us to believe, on such evidence, in the curative effects of an agent, till now forbidden on intelligible grounds, when the Press teems with boundless encomiums, even from the most respectable quarters, of kinds of treatment against cholera, which fail as invariably as they are tried on a sufficient scale?

We admit the efficacy of ice as a means of checking vomiting, and most probably this is the source of Dr. Arnott's apparent success. But there are two things to be borne in mind as most materially affecting our judgment of his communication; first, that vomiting and purging yielding to ordinary treatment prevail at this season, altogether independently of the presence of Asiatic Cholera; and, secondly that out of every hundred cases of genuine Asiatic Cholera, a certain number, (not less, we think, than thirty), recover, without treatment under the most unfavourable circumstances. And, when we say unfavourable circumstances, we do not include such untested and hazardous modes of treatment as Dr. Arnott proposes; for it is surely not only possible, but extremely probable, that a greater or less proportion, or even the whole, of the 30 per cent. just referred to, may be sacrificed to the wild plans of treatment suggested by visionaries. Fortunately for humanity, it often happens that such dangerous designs (and this is the case with Dr. Arnott's proposal) cannot be carried out to the extent directed, because sufficient means are not at hand for the purpose. Dr. Arnott acknowledges the difficulty of carrying his plan into complete effect, and he must excuse us for thinking that his two patients probably owed their escape to his failure to accomplish what he so earnestly recommends.

The sentiments put forth in Dr. Arnott's letter of reproach are far from impressing us with confidence in his judgment with respect to the observation of before untried remedies. On his veracity and honesty we do not cast a shade of suspicion. In the whole communication we discover but one satisfactory statement, namely, a qualification to the effect, that it is the short and limited application of cold that he advocates. If this qualification was all along in his mind, he must have taken much pains to conceal the expression of it, in some corner, probably, of his Pamphlet. In his communications on the treatment of cholera, he nowhere, before his last letter, makes any such limitation. All his previous statements tend to suggest the idea that he thinks the treatment by cold cannot be carried far enough. We are glad, for the Doctor's own sake, that he has thus limited his proposal; but even after this restriction our objection remains unsatisfied.

"Greater medical improvements," the Doctor says, "have been, at first, no better received." Is it a just cause of complaint, that every novelty in medicine is made to pass through an ordeal, severe in proportion as it deviates from previously-received views? But if Dr. Arnott be confident that his proposal can go through the necessary ordeal, why does he retort upon those who simply refuse to it their confidence, till it has been subjected to the usual tests? Surely Dr. Arnott must perceive, that the most notorious of Quacks can say of the opposition made to his nostrum, that all great medical improvements have met with resistance. If many of Dr. Arnott's patients, as he says, have been treated by benumbing cold in the presence of other medical men, why does he not ask them to corroborate his statements, as far as the circumstances fell under their notice. We assure him, the Profession at large stand aghast at his statements, and, without corroboration, will remain incredulous.

The Doctor next asks, "Whether it be a sufficient reason to distrust an experimental fact, because it does not accord with preconceived theoretical views?" No such idea occurred to to us. We said his proposal "is at variance with every received principle of physiology, in regard to the relations of temperature to life;' but these principles are not theoretical views but well-established general facts in regard to the incompatibility of all the phenomena of organic bodies with certain degrees of cold And we added, "when things are brought forward in the character of facts which contradict all our past experience, and all our received views in relation to living action, *we require something more than common evidence before we yield our assent.*"

Again: Dr. Arnott affects to think that we objected to his proposal on account of its novelty. We made no such objection; on the contrary, after stating, that it is a proposal wholly new to the practice of Medicine, by adding that we had no unalterable opinions, we distinctly indicated, that our objection was not its novelty, but a defect of that sufficient evidence which a new proposal requires in respect to the facts on which it is founded.

Neither did we say, in the words put into our mouths by the Doctor, that refrigeration must be bad in so exhausting a disease as Cholera; but we asked, as we ask still, how we should be expected to believe, on such slender evidence as he has furnished, in the value of reducing the temperature of the stomach to the zero of Fahrenheit,—and this we maintain was his original proposal,—without any mention of limit as to time?

The Doctor's next proposition shows a calibre of mind which cannot be too much distrusted in the suggestion of innovations on established usages. "If ice," he says, "has been deemed a most beneficial remedy, why should not a greater degree of cold than that of melting ice, properly applied, possess greater power!" If we were capable of being astonished by anything, this sentence would certainly astonish us. The beneficial effects of ice rest on experience,—experience is the ground on which our faith in it is founded,—but we do not yet believe a greater degree of cold to be more beneficial, because there is no sufficient experience in its favour, and because the same kind of evidence has not hitherto proved it to be free from danger. Our readers remember that some people have lost their lives by Morison's pills carried to excess. In this case, the Doctor seems to have borrowed the kind of logic which betrayed some of the ignorant vendors of those pills into the crime of manslaughter; it is the natural reasoning of men unacquainted with the laws of the living body,—if the four or five grains of gamboge contained in a few of our pills produce effects so beneficial, forty or fifty grains must be ten times more useful; and by this simple formula, now made his own by Dr. Arnott, they innocently cured their victims of all human sorrows.

The Doctor then asks, triumphantly, if there be any reason for fixing the degree of cold at 32 deg. Fahrenheit, because water happens to freeze at that temperature," as if frost-bite were not known to be an effect of the local application of cold, and as if water capable of freezing formed no part of the living body.

Dr. Arnott's next grand discovery is, that two blacks make a white. Have not the majority of the remedies which have been employed in the advanced stage of Cholera been of a dangerous character?" Why, then, he wishes us to infer, should we be afraid to put snow and salt into a man's stomach? This argument worthily crowns the whole.

If Dr. Arnott finally succeed in establishing the safety and ability of a zero-cold applied to the membrane of the stomach, we shall not promise to cry "*peccavimus*," because, even in that

event, we shall feel that we did nothing more than our duty in resisting insufficient evidence; but we shall be among the first to congratulate him on his success, and to proclaim his praise, provided he do not ask us to pronounce him a sound logician.

MEDICAL EDUCATION IN FRANCE.

At the present time it may not be inopportune to notice briefly the system of Medical Education pursued in France and compare it with that which prevails in our own country. Comparisons, they say are odious; but this must apply to persons, not to things, for an equitable comparison often leads to the detection, if not to the remedy, of error.

The first object of every reformer is to point out abuse; the next, to find a remedy for it. Now, it may be laid down as an axiom, that the chances of abuse in any system are proportionate to its complexity, just as the chances of error are greatest in an algebraical problem containing many terms, or as a machine is liable to derangement in proportion to the multiplicity of its parts. In England our Medical system is hydra-headed; or, rather, like the herd of the Evangelist, possessed by a legion of ill-regulated spirits.

In France, the system is remarkably simple throughout, and hence the main characteristics which distinguish the systems on either side the Channel. On the one we have complexity and confusion—envy from a multitude of conflicting interests—injustice from undue preference, and a want of uniformity, which renders it impossible to place a fixed value on our medical denominations. We have Members and Licentiates who are not Doctors, and we have Doctors without a license to practise. We have Members, Fellows, and Licentiates, each claiming separate privileges, and from their privileges inferring a superiority of scientific rank, which, in its turn, they assert, infers superiority of talent or qualification. We have M. D.'s and M. B.'s, the only difference between whom consists in the colour of a cloth. In fine, we have some twenty or thirty Medical Mints at work in every corner of the kingdom, manufacturing Hippocratic coins, which neither bear the same stamp, nor are of the same value, though that which they are supposed to represent be one and indivisible.

In France, the system pursued is totally opposite, having for its object the production of a single class of Practitioners. all emanating from the same source, governed by the same laws, endowed with the same privileges, and, as nearly as circumstances will permit, representing before the public, the same amount of professional value.

Here we do not fall into the error of placing the cart before the horse, and testing the student's *preliminary* knowledge at the *end* of his career. Before matriculation, the student is compelled to take the degree of Bachelor of Letters, to obtain which a very moderate acquaintance with Latin, the elements of mathematics and natural philosophy, is necessary. He is thus prepared to understand the terms of his profession on the commencement of his studies. Unlike a Yorkshire doctor, of our acquaintance, who surrounded all cutaneous eruptions with an "Hariola," and placed the portis dura in the "Polipeteal space," once matriculated, the student's career is free to the end of his education. He pays a small sum quarterly towards the support of the Faculty during four years; has gratuitous access to all the Hospitals of Paris; is emancipated from the despotism of certificate-mongers *et hoc genus omne*, and, finally, having undergone a searching and practical examination in Medicine and Surgery, goes forth, under the title of Doctor, to practise his Profession in any part of the Republic, meeting every *confrère* as his equal, and everywhere accepted as a fully qualified practitioner.

On the other hand, the *pharmaciens*, or pure Apothecaries, are compelled by law,—and, indeed, incited by individual interest,—to confine their operations to the sale of compounds. No Apothecary, in any of the large towns throughout France, will make up the most trifling compounds—say salts and senna—without the prescription of a Medical Man. Hence the latter are called in for the most trifling affections, and, as their fees are extremely moderate—in the populous quarters seldom exceeding two francs, or 1s. 8d., everybody is content; the Physician because he has plenty of patients; the Apothecary, because he has plenty of prescriptions, and the public, because they obtain the best medical advice at a moderate cost.

And, let it not be imagined that the consideration of the Medical Man suffers from the modicity of his *honorarium*, or that the fee is inadequate to his comfortable support. For, on the Continent, a man's merit is not measured by the length of his purse; and ostentatious efforts to appear more than what you really are, instead of exciting admiration, merely elicit contempt. No one ever dreams of thinking that a carriage or a cook, servants in livery, and sumptuous fare—in fine, an establishment which, three times out of four, crushes the unfortunate aspirants—no one, we repeat, thinks of connecting these vanities with the practice of medicine. A simple and often poor apartment in an obscure court—a clean *bonne* to open the door—a few books to look like a library—a daily outlay of four or five francs—such is the capital of the Medical Man at the commencement of his career, and from this humble origin—if he have talent and good conduct—does he frequently rise to the highest rank in the commonwealth of medicine.

All this is effected through the agency of the "Concours;" and to the consideration of the influence of this admirable Institution on the progress of medicine we shall shortly return.

REVIEWS.

On Healthy and Diseased Structure, and the true Principles of Treatment for the Cure of Disease, especialy Consumption and Scrofula. Founded on Microscopical Analysis. By WILLIAM ADDISON, M.D., F.R.S. 8vo., pp. 320. London: Churchill, 1849.

Dr. Addison is well known to the Profession by his microscopic researches. The value of the microscope, as an aid in the study of the science of medicine, is beyond doubt. Ere many years have elapsed, the pathologist will be considered to be as unfit to undertake the examination of a body after death, unassisted by that instrument, as the Practitioner to treat pulmonary disease unaided by the stethoscope. The microscope bears the same relation to pathological that the stethoscope does to clinical investigations; it enlarges the field of our observation, and renders more precise the information gained. But at the present time there are men who sneer at those who habitually use the microscope, and taunt them with wasting their time on trifles, instead of devoting their energies to practical researches; as though whatever aided diagnosis was not necessarily practical. To the success of the treatment employed by the blind empiricist, and that devised by the rationalist, accuracy of diagnosis is equally essential, and, what is of far more moment, the labours of the man who endeavours to ascertain the value of therapeutic agents by induction are lost, till the diseases, his power of combating which he is testing, are defined by unequivocal limits. Accurate diagnosis is the foundation of all therapeutic researches, and, therefore, whatever affords assistance in diagnosis must practically advance the science of medicine. Our generation has witnessed the introduction of the stethoscope and the pleximeter, and the systematic application of chemical and microscopic researches to pathology. These, however, are but adjuvants to the methods of investigation employed by those who have gone before us; and the attempt to exalt either, above its true level, can only retard its general employment. Such was the fact with regard to the stethoscope, such has been and still is true with regard to the microscope. Dr. Addison, in our opinion, endeavours to assign to the latter instrument powers it does not possess, and, therefore, desirous as we are of seeing it occupy its true position, we cannot but regret his misdirected zeal.

The microscope takes cognizance only of objects of vision—form, and colour. Now, two bodies, which are homogeneous and colourless, and which to the eye, consequently, are identical, may be functionally very different; so that the microscope fails us when we proceed to an ultimate differential analysis, even visually considered. The protoplasma of the most different] structures, so far as the eye aided by the most powerful glasses can discern, are identical; and we distinguish them from each other only by the inherent difference in the function of each. If that function be to develope complicated structures, as cells, so soon as those cells are formed so soon can we distinguish the one blastema from the other, *i. e.* by the difference in the shape of those cells.

The protoplasma of cancer, of tubercle, and of ordinary adhesive tissue, is, so far as the microscope reaches, identical; but when respectively cancer cells, tubercle corpuscles, and fibrous tissue are developed, the eye is enabled to distinguish the one form of matter from the other, and we acknowledge that the blastemata from which they severally sprang were not identical.

Dr. Addison states, "results derived from microscopical researches, to be of practical utility must be admitted into the domain of therapeutics and cure." The microscope "will enable us to extend our remedies, and to suggest new physiological methods of treatment for the maladies of mankind."

Here we differ from him *in toto*. Microscopic research does not enable us to add one therapeutic agent to our catalogue, or to apply one already used in a manner different to that in which we heretofore employed it; but, what it does enable us to do, is to arrive at a diagnosis, without which we could not estimate the value of the remedy. Let us illustrate this statement; the propriety of removing a carcinomatous growth is an important medical

question; the microscope enables us to distinguish carcinomatous from all other tumours, which the unassisted eye does not; now, if every tumour removed by the surgeon as carcinomatous were examined by the aid of the microscope, we should, in few years, be in a position to determine, by a careful examination of the facts observed, the value of the operation. Our knowledge of the structure of cancer in this case sheds no new light on its treatment; but by circumscribing within precise limits the meaning of the word it enables us to estimate the value of the therapeutic means we are employing. The fact of young epithelium scales in some cases closely resembling cancer cells, and the very rare occurrence of undoubted carcinomatous tumours without diagnostic cancer cells, offers no practical objection to the above illustration.

Dr. Addison's theory of tubercle is, that it is "retrograde morphology." To illustrate and apply this definition of tubercle is the whole purport of the book before us; and if we can succeed in explaining to our readers the meaning of the above definition, they will at once comprehend all that the work contains having the slightest pretension to originality.

Dr. Addison has derived his theory from the doctrines of vegetable morphology. The leaf, our Author allows, is the primary organ of vegetation; the bractæ, calyx, corolla, stamina, ovaria, &c., are, according to vegetable physiologists, but metamorphosed leaves. If certain unfavourable external conditions, or some inherent defect in the constitution of the individual exist, this normal metamorphosis does not occur, but the leaf with its peculiar cell tissue, *i. e.* the primary organ of vegetation, occupies the place of the petal. If, however, the petal be but a metamorphosed leaf, and a leaf replace the petal, it is evident that there can have been in such case no retrograde metamorphosis, but simply a want or failure of metamorphosis. Passing by the inapplicability of the term "retrograde," we understand Dr. Addision to mean by the expression, when applied to pathology, a return to the embryonic structural elements in any part.

"Following the analogies in vegetable bodies, we propose," says he, "to demonstrate the law of development of the textures of the human structure, to show, that they all originate from the metamorphosis of cell-organisms in the embryo; and are displaced, interrupted, or go back to cell-organisms in scrofulous disease, phthisis, and ulceration."

And again—

"We simply prove, by microscopical demonstration, that in consumption and scrofulous disease, cell-organisms, characteristic of the embryo structure and of blood, re-appear amongst, and supplant the elements characteristic of the healthy adult texture."

And further—

"Scrofulous diseases express the retrogradation of a special texture to some earlier cell-type. And consumption is the retrogradation of the pulmonary or respiratory parenchyma."

If this be true, at least the structure of tubercular matter ought to be identical with that of some normal organic constituant of the embryo—we say at least, for, to prove identity there should not only be identity of visual organization, but identity of function. We assert, that tubercle is not identical in structure with any portion of the healthy embryo; although doubtless, the embryo at first resembles recently-formed tubercular matter, in so far as both are formed of "colourless cells and protoplasmatous matter." The microscope affords no means of distinguishing, as we have before observed, any difference in the homogeneous blastema or protoplasma —"that viscous mass which everywhere precedes the first solid formation;" but we think no doubt can be entertained, that the cells of tubercular matter possess characters which forbid their being confounded by the eye with any normal embryonic structure. Our readers will not wonder that Dr. Addison differs from Lebert as to the existence of cells proper to tubercle, when they compare the description of the corpuscles in question by the two observers; nor will those, unable themselves to ascertain the truth by personal observation, hesitate as to which they shall trust.

"In our observations," remarks the former, "almost all the cells of the most recent tuberculous matter have presented a coarsely granular appearance, being crowded with dark particles, apparently of a fatty or oily matter."

The corpuscles or globules proper to tubercle are thus described by Lebert—

"The constant and characteristic element of tubercle is the tubercular globule, which may be thus distinguished from every other primary element whether normal or pathological. It is rarely round or oval; although always irregular, it approaches, more or less, one of the above shapes. Its outline is usually angular, the angles being rounded when they are seen on one side; rather polyhedral when they float, which they must do in order that their surface may be seen distinctly. The surface, although irregular, is smooth, and granules are never observed sticking to it. The size of one of these globules varies as a mean between 1-140th and 1-120th of a millimetre. When the globules are somewhat ovoid, the average of their breadth is 1-130th of a mill, while their length varies from 1-120th to 1-160th. Their contents consist of a more or less transparent mass and molecular granules; these granules vary in number;—sometimes there are four or five, sometimes as many as ten and more. However, they are never as numerous as in granular corpuscles properly so called."

Now, taking the characters given above by Lebert as those diagnostic of the tubercle corpuscle, we maintain that there is no globule in the embryo identical with it, none to which the above description is literally applicable; and if, as we believe, our assertion be true, then does the theory of retrograde metamorphosis fall to the ground, and with it all the speculation built on its foundation.

But even if the globules observed in tubercular matter were identical in form with those normally existing in the embryo, still the *function of* the former, and of those seen in the embryonic structures are not identical, and, therefore, tubercular matter cannot be regarded as a retrograde metamorphosis in the same sense as the leaf which replaces, or stands in the stead of the petal, is a retrograde metamorphosis of a petal, for that leaf is, to all intents and purposes, a leaf in function as well as in microscopic structure.

We think Dr. Addison's mode of reasoning on this matter, may be syllogistically expressed, thus,—the embryo, when first visible, is composed of colourless cells and protoplasma; tubercle and the incoherent cell products of inflammation are composed of colourless cells and protoplasma, therefore the latter are identical with the embryonic texture. The fallacy lies in the fact, that the protoplasma and the colourless cells of these structures are not identical.

Such, then, is the basis on which Dr. Addison has raised the superstructure of his work. Let us examine a little that superstructure, and see if even the foundation had been correct, it could have supported any valuable conclusions, or if our Author, although he has started from an error, has managed to stumble on truth as he has proceeded in his labours; if he has added aught new or important to our literature of the symptoms, causes, or treatment of scrofula and consumption, already too redundant.

Having stated the views we have above criticised, our Author devotes the first chapter of the first part of his Work to Practical Physiology. In it we find the following practical information, that when serous membranes, *e.g.* the pleura and peritoneum, are inflamed they become covered with villi, such as "constitute the distinguishing features of a mucous membrane." Now, we know only one tract of mucous membrane covered with villi, viz., that of the small intestines; and, although we not unfrequently examined the serous membranes specified, after they have suffered from inflammation, we certainly have failed to detect on them any bodies identical in organization with the villi of the intestinal mucous membrane.

The process of growth is, according to Dr. Addison, "not a species of exosmosis through a structureless membrane with the genesis of cells from germs in the exudation, but a phenomenon of morphology." But we must doubt if he was not deceived by some optical illusion when he saw, as he informs us at page 43, the fibrous texture "become again corpuscular." So far as our observations extend, a cell once formed or developed into a fibre, never reverts to the cell condition.

Under the head of "Practical Pathology," which forms the second Chapter, is a section on inflammation, in which is the following statement:—

"A person is severely burnt. The exciting cause, a hot iron, acts momentarily and only once; but having acted, the morphological phenomena will ensue, new morphological elements will appear, and the living texture will disentangle itself from the dead.

"The sore of a burn in its granulation state is, strictly speaking, scrofulous."

That is, a healthy granulating ulcer is a scrofulous sore. To such of our readers as have experienced the difficulty of healing scrofulous ulcers, this statement will appear very misplaced in a chapter on *Practical* Pathology. Because the microscope exhibits no difference in the secretion from the surface of an ulcer in an undoubtedly scrofulous individual, and that from an ulcer the result of a burn in a healthy person, to declare that the two sores are identical, appears to us about as well-founded an assertion, as that water and alcohol are identical, because we can by aid of the microscope detect no difference between them; or that isomorphous crystals, the most dissimilar in composition, are the same, because the eye cannot discriminate them from each other.

Passing by the chapter on "Practical Psychology, in which our Author has

"Wrapped nonsense round
In pomp and darkness till it seems profound,"

while his

"Reason, like a pale-faced mummy stands,
With her arms swathed in hieroglyphic bands,"

we reach the Second Part, containing the Symptoms, Causes, Therapeutics, and Cure of Consumption; and in this Chapter, as if to console us for the depth of the last, we enjoy the lightest of reading.

The chest is divided vertically from front to back into two compartments by a membranous partition or fold of the pleura; on one side of this partition is placed the right lung, divided into three lobes; on the other is the left, divided into two; the place of the third being, as it were, occupied by the heart, *which lies on this side of the chest.*"

Yes, in a monograph on Consumption, published in 1849, the medical (?) public is informed that the heart lies on the left side of the chest, and, further, that "the air penetrates into the lungs through the *windpipe, a round tube which may be easily felt running down the front part of the neck,*" &c. &c. Throughout the whole of the Second Part there is not a single new fact, not an original idea.

With respect to "Therapeutics and Cure," the Law of Retrogradation, of which Dr. Addison supposes himself the discoverer, has enabled him to add but little, yet that little is extended over one

hundred pages. To prevent or arrest consumption in its early stage, we are directed to remove irritating conditions, and to use "judicious measures." In the more advanced stage, if we "confine our expectations within the limits of natural laws," we are told, that "we may hope to arrest the progress of a retrograde metamorphosis, *by promoting the fibrous type in the secreting walls* of cavities;" that is, we are to replace the cavities by fibrous bands, cartilaginous cicatrices, &c., and then alter the constitution. But how? "In the cure of consumption, we demand an alterative that shall promote a change of structure, and alter a morphological type; that, meeting with an unnatural cell-growth, shall arrest it, and give opportunity for the vis medicatrix, absorption and fibrous cure, to come effectually into play."

Tubercle, says Dr. Addison, is a growth; "mercury, arsenic, and agents of the like nature, readily interfere with and stop growth." All the practical or theoretical hints as to treatment we have been able to gather from this, the longest chapter in the book, may then be thus summed up; in the first place, we are to remove irritating conditions, and use judicious measures—*i.e.*, place our patients in favourable hygienic conditions; and, secondly, we are to check the growth of tubercle by mercury, arsenic, and agents of the like nature. The latter part of this treatment is founded on the assumption that tubercle is a growth. Now we are prepared to affirm, that tubercle is not a growth. One of its characteristics is, that, once formed, it has no power of increase within itself,—it never grows; true, it first appears as a point, and is afterwards a large mass, but such increase in size is purely mechanical. If, then, Dr. Addison has found by *experience* that mercury, arsenic, &c., are curative agents in phthisis, that they favour the healing of cavities, &c., they must have acted in some other way than by checking the growth of tubercle, for that most assuredly never grows.

From this analysis we think we are justified in particularizing a general statement we made above, by asserting that the microscope has failed in the hands of Dr. Addison in adding one new remedy to our catalogue of therapeutic agents, in suggesting even one new mode of treating the diseases he has discussed.

In conclusion, we may add, that nothing but a desire to save the microscope from the contempt which such a production was likely to bring on it would have tempted us to enter so fully into the demerits of Dr. Addison's Work on Consumption and Scrofula.

CHOLERA CORRESPONDENCE.

DR. BRITTAN'S CHOLERA VIEWS.

SIR,—It is not my intention in this communication to attempt by any means to deprive Dr. Brittan of the honour due to him for his supposed discovery of the causes of cholera. Still I think I am bound, in justice to myself, to say, I had concluded from the long series of microscopic observations I have been making for some years past, that whenever the cause of Asiatic cholera was discovered, it would be traced to fungi. My microscopic observations have been conducted as an amusement; and I have found, in pursuing them, that the principal diseases incidental to the vegetable world may be traced to fungi. The question then resolved itself—May not the animal creation be subjected to similar attacks?

My ideas had been communicated, during the last two months, to many non-professionals persons; but, on the morning of Sunday, Sept. 23rd, having had occasion to call on my medical adviser, S. Brougham, Esq., of this town, I, in the course of conversation, mentioned to him my ideas on the subject of cholera, and put several questions which I considered bore on my views. He informed me he had not, in his practice, met instances to enable him to give positive replies; but if I would commit my queries to paper and give them to him, he, being a subscriber to the *Medical Times* Journal, would forward it, and, no doubt, amongst the very numerous subscribers to that Journal, satisfactory replies would be obtained.

Being confined to my house and bed, from Monday, September 24, to Monday, October 1, I had no opportunity before now of submitting my queries to paper. Last evening Mr. Brougham paid me a professional visit, and then informed me he had seen a Report in the *Medical Times* he had just received, which bore on the subject I had mentioned to him *the week before*, and would lend me the Paper for the evening, which he did. Not being of the Medical Profession, it was the *first time I had ever seen the Medical Times, and the first time I had heard of the question of fungi being entertained by any other person than myself.* I have not, in the slightest degree, brought this subject forward with a view of snatching the laurels from Dr. Brittan's brow to place on my own—I have not the slightest pretensions to that. Dr. Brittan is entitled to every honour and credit for his researches, which appear to have been conducted in a systematic and scientific manner, and to entitle him to the homage of every well-wisher to his fellow-man. I have brought it forward only with a view of showing that similar ideas may strike persons unacquainted with each other, or even connected in the same branch of science.

Fearing I may be trespassing too much on your valuable space, at the same time hoping you will favour me with the insertion of the following queries, in which I feel interested, I subscribe myself,

Sir, your very obedient servant,

E. GILBERT, Civil Engineer.

Falmouth, Oct. 1, 1849.

QUERIES.

1st. Has there ever been a correct analysis of the discharges from the stomach or bowels of a cholera subject *in the different stages of the disorder?* If so, was the liquid properties an acid or an alkaline?

2nd. Has there been an analysis, or any observations recorded of the nature of discharges from the stomach or bowels of a patient who may have been poisoned by eating fungi, *i.e.*, the mushroom family? And what appearance did the patient present when labouring under the effect of that poison *just before* and after death?

3rd. Has there ever been an analysis of the discharges from the bowels of a subject labouring under the effects of a violent diarrhœa? If so, did it partake most of an alkaline or an acid character.

E. G.

[The priority of having first entertained the idea that cholera depended on the presence of fungi in the atmosphere must be accorded to Professor Mitchell, of Philadelphia, whose ingenious work on the Cryptogamous Origin of Fever, Cholera, &c., we reviewed three weeks since. His views were imbodied in a course of lectures delivered at the Jefferson Medical College during the session 1846—1847. In the Introduction he thus addresses the gentlemen who, at that time, composed his class:—"To you I had the honour of delivering, nearly in their present shape, the lectures which I now send to the press. Previously, I had not put my ideas on the subject of which they treat into so formal a shape, although I had announced *for years* to each successive class, my impression that, possibly, the photophytes might afford a good explanation of the causation of malarious and other diseases of a febrile nature. Of the production thus, at least, of yellow fever and cholera, I entertained less doubt, and taught, therefore, the sentiment with less reserve." And further on, he continues: "Experiments are in progress, which seem to promise more direct and unquestionable proof of the validity of our hypothesis."

In this country, Dr. Cowdell, of Dorchester, published, in 1848, and before he was acquainted with Professor Mitchell's labours, a fungoid hypothesis in a clever and interesting work entitled, "A Disquisition on Pestilential Cholera, being an attempt to explain its Phenomena, Nature, Causes, and Treatment, by reference to an extensive Fungoid Origin." To this, and to Dr. Mitchell's work, we would refer our correspondent.

In answer to our correspondent's queries, we may inform him, 1st., Dr. E. A. Parkes, Professor of Clinical Medicine at University College, examined stools passed by Cholera patients in the diarrhœal period, the early algide stage, the moderately developed algide stage, the intense algide stage, at the commencement of re-action, and during relapse. In every case they were alkaline. See an able paper by that gentleman, in No. II. of the *London Journal of Medicine*.

Professor Hermann, of Moscow, in 1832, on the contrary, found that they had an acid re-action, and resembled the vomited matter, in which he stated, that he detected free acetic acid. All other writers concerning the former and present epidemic, so far as we know, agree with Dr. Parkes.

2nd. Professor Mitchell thus sums up the phenomena attendant on the introduction of a fungous poison into the system. After a time "it excites a morbid action of a febrile character, continued in some cases, remittent or intermittent in others, which is followed by abscesses or gangrene, and occasionally by locked-jaw and yellow skin." For more detailed accounts, we must refer our Correspondent to Pereira's "Materia Medica," and to Dr. Christison's "Toxicology." We are not acquainted with any recorded analysis of the matter discharged from the stomach or bowels of a patient poisoned by fungi.

3rd. In bilious diarrhœa, Simon states, the stools have a strong acid re-action. Dr. W. B. O'Shaughnessy said, in 1832, "of more than 100 cases of ordinary diarrhœa the dejections examined by me presented *no single* character of the cholera evacuation." Dr. O'Shaugnessy found the stools invariably alkaline in true cholera.

Let the writer of the above letter understand, that of medicine the saying *is true*:—

"A little knowledge is a *dangerous thing*."

And that, if a man would avoid inflicting injury on his fellows, he must

"Drink deep or taste not."

Men who are blind may walk on turnpike-roads, and think that they are treading unknown regions, because they cannot see the mile-stones and the way-posts placed there for the benefit of those whose eyes are open; and he who journeys through unknown and intricate paths, in darkness and without a guide, will very rarely, indeed, reach the point at which he aims.—ED. *Medical Times.*]

LETTER FROM HENRY W. LIVETT.

SIR,—I send you the following facts relative to the recent outbreak of cholera here, for publication in your journal, should you think their bearing upon the "*questio vexata*" of contagion sufficiently interesting to your readers.

On the 2nd of September I was called up at about six a.m. to see a woman named Pike, who had been taken suddenly ill a few hours before. I found it to be a well-marked case of spasmodic cholera, and it proved fatal in twenty-two hours. An inquest was held on the body, but as there was a great disinclination in the townspeople to admit that cholera had really appeared, the jury returned a verdict, contrary to my opinion, of "Died from protracted diarrhœa." The mother of this woman (case No. 2) came from a village eight miles distant, and nursed her for a few hours previous to her death; the mother lodged in a clean and different part of the town, was attacked by cholera on the 6th, and died in twenty-four hours. The linen belonging to the first case was washed in a house quite at another end of the town; and there, on the 6th, two cases occurred, both fatal; one in five hours, the other in eighteen. The linen was ironed in the adjoining house, and there, and in three following ones, one fatal case occurred in each house within two or three days. An old woman living about a mile out of town, nursed and laid out after death case No. 2, and was herself attacked on the 10th, and died in thirty hours. From that period to the 20th I had seven cases (two fatal), five of which occurred in the families of persons *related to those previously deceased*, and above enumerated. These cases occurred in *various localities*. No case has occurred since the 20th. I may add, that four cases were attended by other medical men during the above period, all fatal, but I believe not connected with those I have named.

We have, therefore, had in Wales, in the three weeks, nineteen cases; thirteen of which can be distinctly traced to the first, the woman Pike. In no other way can I account for the disease appearing as

it did, almost simultaneously in various quarters, the only persons attacked having been in personal attendance upon the dying and the dead, for a short period, a few days previously.

I will not enter into details respecting these cases, nor the treatment; contenting myself with the bare facts, satisfied that they are in themselves sufficient for the consideration of your readers.

I am, Sir, your obedient servant,
HENRY W. LIVETT.

Wells, Somerset, Sept. 27, 1849.

LETTER FROM JOHN W. HUNTER.

SIR,—I trust I may be excused for sending you the following mite of experience relative to that *questio vexata*, the treatment of Cholera. I have been called upon to attend only three distinct and unequivocal cases of that disease, all exhibiting, however, those characteristic and intense symptoms, indicating the greatest danger, viz., violent retching and vomiting, constant stools, icy coldness, most painful cramps, altered and Hippocratic physiognomy, scarcely perceptible pulse, blue skin, and black nails.

I strictly followed up the saline treatment, as recorded by Dr. Stevens, in the *Medical Times*, September 1st, applying, in addition, external heat and mustard plasters to the stomach. I was both pleased and surprised at the speedy effects of the treatment, as a few hours' perseverance procured complete relief of the most painful and dangerous symptoms. A less frequent use of the remedy in a few days rendered the first two patients convalescent.

The third case was a patient above seventy years of age, a constant invalid, and reduced by sickness and disappointment previously, so that she sank from exhaustion; yet I consider the saline treatment *so far succeeded* that the vomiting and cramps were greatly diminished and the warmth restored.

At a time of such serious alarm and mortality from this disease, I may perhaps be pardoned for making a few further remarks. The above three cases may be thought to go for nothing, but the *speedy effects* of the saline treatment, in each individual case, were to me astonishing, and seemed marvellous to the first two patients and their friends; for, without my drawing it from them by questioning, they have subsequently volunteered their convictions as to the efficacy of the "salt," contrasting the results with what has occurred *within their own observation*, to patients treated with "brandy," *i. e.*, probably the stimulating treatment, with or without calomel or opium, viz., that all those persons attacked with cholera about them, twelve in number, and treated with "brandy," had all died.

In the more ordinary forms of diarrhœa, I have also found the saline treatment equally beneficial in relieving the irritation, and restoring the healthy action of the alimentary canal.

I beg to remain, Sir,
Your obedient servant,
JOHN W. HUNTER.

30, Wilton-place, Belgrave-square.

THE MEDICAL PROFESSION AND THE POOR-LAW.

[To the Editor of the Medical Times.]

SIR,—You have done me the honour to notice with approval, a recent attempt of mine to plead the cause of the industrious working man, *versus* indiscriminate almsgiving and the Poor-laws. Will you allow me to invite your attention to what appears to me a very grave question. Is the Medical Profession interested in the maintenance or repeal of the Poor-laws? One thing may, I believe, be taken for granted in discussing this question; namely, that the present scale of Poor-law remuneration is so low, as to be in most cases no remuneration at all. Now, if we suppose the Poor-law to be abolished, the Medical man benefits as a rate-payer, to the extent of his Poor's-rate, whatever that may be; so that the question assumes this practical shape:—If the Poor-law Medical Officers were to cease to be employed as such, in consequence of the repeal of the Poor-law, and the rates they now pay were left in their pockets, would they not be gainers by the change? Some will answer this question one way, some another. Those who are most liberally paid, and whose rates are most moderate, will probably discover that they would be losers by the change. To these parties, then, I address myself. I think I may safely assume that, when their balance of profit and loss is struck, they do not find themselves much the richer for their Poor-law stipends; and I feel confident of being able to prove to them, that their few pounds of surplus would accrue to them, after the repeal of the Poor-law, in a much more agreeable way, and with sure addition. In the first place, there are many persons, in every part of the country, (and their number is increasing since the Government were so foolish as to defray half the expense of medical attendance out of the Consolidated Fund,) who get orders for medical relief, being all the time in a condition to pay for medical attendance, and who would be better paymasters than the Union. Again, it must be borne in mind that the sum raised annually for the relief of the poor goes to impoverish the medical man's natural customers, many of the smaller rate-payers being, as everybody knows, just on the very brink of pauperism themselves. And what is the sum thus annually deducted out of the labour-fund to be expended in workhouses? It is, in round numbers, about six millions of money. Of this immense sum, if allowed to be expended out of the workhouse in preventing pauperism, instead of being spent in it, in petting and coddling, in a fantastic, tyrannical sort of way, the victims of the Poor-laws' immoral teachings and mischievous temptations; of this immense sum, the Medical Profession would certainly have a very fair share, at the same time that it would partake of the prosperity engendered by that large portion of the six millions which would be spent reproductively. I dare say, many of your readers, perhaps, even yourself, will be somewhat startled at the idea of following up the repeal of Protection to *British Industry* by repealing the *Protection to British Idleness*, especially as Ireland has lately had a Poor-law forced upon her as a panacea, and our most influential organ of public opinion believes in this strange remedy as devoutly as many a fanciful valetudinarian in the virtues of Homœopathy. But, Sir, in the face of all this weight of precedent and authority, not forgetting our own excellent Dr. Alison's pleadings in its favour, and Lamartine's recent attempt to introduce the system into France, I still contend, with Malthus and Chalmers, and the author of the "Original," that a Poor-law is a delusion and a snare, and a source of degradation to all who have to do with it. Pray let the Profession have your views on this subject, and oblige, Sir, Your obedient Servant,

A LONDON PHYSICIAN.

NECESSITY OF MEDICAL REFORM.

To the Editor of the Medical Times.

SIR,—There is no other illegitimate trading on the community so dangerous and so tolerated as quackery; and this is a matter for grave astonishment, when we think of the general devotion to every pursuit and object which can promote health and prolong life. That victims follow the nefarious traffic of the selfish pretender who lives upon credulity and failing health, there can be no doubt; that this monster evil will work its cure by its own growth, by its enormities becoming too flagrant to be tolerated, 's the only consolation that arises from its daily increase and thriving prosperity. In reading a book -"Confessions of a Hypochondriac"—which teems with denunciations against quackery, I met with the following suggestive paragraph; it is true and pertinent, and worthy of consideration:—"The House of Commons is sensibly indifferent to the interests and rights of the Medical Profession." Mr. Wyld, M.P. for Bodmin, uttered this notable fact the other day at the London Tavern. A political body has no great concern for a civil body of no political importance. It is nothing wonderful. In proportion to power is respect ever doled out. But, are not 30,000 men (is not this an over-high calculation) of acknowledged talent moving in all ranks, from the Prince to the peasant, a staple Company for good or evil? Have they not a power? Is it not growing daily by union and action? The power which knowledge gives. Let them but press the members for boroughs, cities, and counties, on their just rights, and truth backing them, they are not so powerless a body that they can be treated with inattention. "We have been promised a Medical Bill!" A consummation most devoutly to be wished. When shall we have it? We have had a sad and long experience of indifference, and is it not the result of our want of political weight in the State? No one would wish the Profession to become a so-called political body, making common cause with the Manchester or any other school; but it would be desirable to have the power to avert the injury and insult of neglect suffered Session after Session. The law's delay is ceasing to be a proverb. The delay of redress for professional grievances has become proverbial. If we cannot embark on the troubled waters of politics, as a body, we should endeavour to acquire our just rights as individuals. By disunity we are powerless; our strength is frittered away by want of unity in action; by the neck-and-neck competition, which places us too much in collision with each other, and at the mercy of every pretender—the Government official and the tolerated Charlatan. Division is the grand secret of our ill success. You, Sir, have often appealed "on the necessity of unity," and too much in vain. The history of politics teaches us how much is done from without; that our lethargic representatives only move when goaded into action by the public and the Press. Why, then, should we not resort to every expedient that can awaken attention? I believe, if the Medical Profession stir, a political position will be easily attained, placing us above the mercy of "the slow movement," and, by a county organization, which would entail no expense, an attention to our wants and rights would be called into life by the next Session, sufficient for every purpose. Personal knowledge and communication have an urgent *prestige*, and nothing would interest M.P.'s individually, like petitions from parties, who must be known to them, upon the rights of the Profession, and the immense injuries inflicted on the public by the present deplorable state of the law.

I remain, sir, yours truly,
CHIRURGUS.

Bristol, Sept. 12, 1849.

THE IRIS A TEST OF THE STATE OF THE CONSTITUTION.

[To the Editor of the Medical Times.]

SIR,—I have, for some time past, been in the habit of regarding the eye as the best test of a patient's constitution; and the result of my observations has been to convince me that the nearer the Iris approaches to a firm, clear-looking, and unmixed colour, (black, blue, and, *perhaps*, hazel,) the healthier and sounder is the constitution. Whenever the Iris presents the appearance of a *broken network*, or the colour is a light watery-looking one, or deposited in darker patches in some places than in others, there is a corresponding degree of delicacy of constitution. Whenever there is an appearance of red, green, or yellow in the Iris, the diseases under which the patient suffers always exhibit an obstinate or malignant character, more especially when the red or green is present. Such persons, moreover, always beget unhealthy children; and we may generally expect to hear of much ill health, serious and obstinate illnesses, and premature deaths occurring in their families.

It is known to the Profession, that an Iris which is wholly red indicates the cancerous diathesis,—a circumstance which I had myself noticed before I was aware of its being already known,—but I believe that the appearance of the light Iris, which answers to the red of the dark one, has not been pointed out, it is the following:—A peculiar hard, pearly, grey look, and, if the eye be closely examined, there will be found immediately around the pupil a circle of a more or less red hue. Moreover, instead of the appearance of a net-work, in which a mesh had broken, leaving a large nearly square space, such as we may see in the light scrofulous blue Iris, there will generally be low, narrow places, giving the idea of the substance of the Iris having been there corroded away: the worse the state of health the darker, thicker looking, and more distinct will be the outer margin of the Iris.

We not unfrequently meet persons having a greenish Iris, who will boast of never being ill, and of being able to undergo considerable fatigue. Such persons are generally stunted in stature; and, in the few instances in which the reverse is the case, they will be found to show signs of failing health soon after thirty, if not before; and, should inquiry be made, it will most probably be found that they are descended from parents, one or both of whom have exhibited marked signs of having an unhealthy constitution, (consumption, epilepsy, &c.) and among their brothers and sisters obstinate affections and diseases of debility will prevail.

I have pointed out the foregoing appearances of the Iris, and the inferences derived from them, to several medical men, to each of whom they were new; this induces me to trouble you with them.

I remain, Sir, your obedient Servant,
GEORGE FEARON, M.D.

Great Charles-street, Birmingham,
September 27, 1849.

INTRA-MURAL BURIAL GROUNDS.

[To the Editor of the Medical Times.]

SIR,—I beg to enclose a copy of the Petition to the Board of Health, drawn up and signed by the Medical Practitioners in St. John's district, Paddington. The grave-yard in question has been

established rather more than eighty years; the average number of burials is 1,200 annually; and during the last ten weeks, 358 have been interred. The ground extends over rather more than five acres, one acre being set apart for the opulent, appears to be but little used. No plan is kept of the relative position of the graves, thus compelling the sexton to resort to the process of "boring" to find a spare place for the next comer.

Trusting our Medical brethren in other districts will unite, in a similar manner, to prevent intramural burials,

I remain, Sir, your obedient servant,
J. Drury, M.D., Hon. Sec.
44, Albion-street, Sept. 20, 1849.

TO THE GENERAL BOARD OF HEALTH.
9, Cambridge-square, Hyde-park,
Sept. 15, 1849.

Gentlemen,—We, the undersigned Medical Practitioners in Paddington and its vicinity, respectfully call upon the Board of Health, to exercise the power with which they are invested, for the purpose of closing the burial-ground of St. George's, Hanover-square, situated in the very heart of this populous neighbourhood.

Firmly convinced that intramural burial-grounds are at all times most prejudicial to the public health, we feel that they are more especially so at a time when the metropolis is afflicted by an unexampled visitation of epidemic cholera.

We, moreover, respectfully urge our petition on account of the notoriously over-crowded state of this particular burial-ground, and indulge the confident hope, that your honourable Board will at once terminate a nuisance, which evidently tends to poison the atmosphere, and to produce the most baneful consequences in this otherwise healthy locality.

(Here follow the signatures of forty-one Medical Practitioners.)

MEDICAL NEWS.

Apothecaries' Hall.—Names of gentlemen who passed their Examination in the science and practice of medicine, and received certificates to practise, on Thursday, Sept. 27, 1849:—John Warren Edger, Kirkby Stephen; Edmund Carver, Melbourne, Cambridgeshire; George William New; Edmund Emra Earle, Bristol; Thomas John Sayer, Keinninghall; George Gibson, Butley, near Gateshead.

Obituary.—At Madras, on the 26th of July, Dr. J. Uppleton, late of Greenwich, of dysentery. On the 1st inst., at North-end Cottage, North-end, James Edwards, Esq., M.D., aged 69, late of Canterbury, and formerly of Putney. Sept. 13th, at Kennitty, King's County, deeply and deservedly lamented, in the prime of life, of brain fever, after a few days' illness, James Willington Walsh, Esq., M.D., Fellow and Licentiate of the Royal College of Surgeons in Ireland, Medical Superintendent of the Kennitty Dispensary and Temporary Fever Hospital.

London Orphan Asylum.—The vacancy occasioned by the lamented decease of Mr. Charles Aston Key, as Consulting Surgeon of this valuable Institution, has been, by a unanimous vote of the Board, filled up by the election of Mr. Thomas Blizard Curling, the recently elected Surgeon to the London Hospital.

The Cholera.—This fatal epidemic continues to decline both in London and in the provinces. The reports from the provincial towns are, on the whole, favourable, though at Bristol the mortality continues very high. The Registrar-General's Report is as follows:—

It is gratifying to observe the further abatement of pestilence in London. After the first week of September, in which the fatality from cholera was greatest, and 3183 persons died from all causes, the total number fell in the second week to 2865, then to 1981; and in the week ending last Saturday, the total deaths registered were 1611. During the same period the weekly numbers of lives destroyed by cholera have been 2026, 1682, 839, and in the last week 434. Diarrhœa was fatal successively to 272, 280, 238, and last week to 163. In comparing the returns for the last two weeks, the decline of mortality is most obvious in the south districts, where the deaths from cholera have fallen from 422 in the week ending September 22, to 161 in the last; and, to take the most striking examples of particular districts, in St. George's, Southwark, they declined from 58 to 10, in Newington from 66 to 15, and in Lambeth from 117 to 50. In the north and central districts the improvement is also remarkable, in the former the deaths from cholera in the two weeks having been consecutively 71 and 37, and in the central having been 95 and 51. The improvement in the east districts is not so great, the 183 deaths of the previous week having fallen to 113 in the last; but in the west districts the public health has recently been stationary, the weekly deaths caused by the epidemic having been 68 and 72, though here too a great change has taken place for the better in the latter half of September as compared with the former. In the whole metropolis the daily number of deaths from cholera last week has fluctuated between 102 and 56, but showing an almost constant tendency to fall. The mortality from small-pox, measles, and scarlatina is much less than the average; from whooping-cough it is near the average; typhus has recently shown a slight increase.

Explosion of a Sewer in the Borough.—On Saturday evening, about six o'clock, a fearful explosion of sewer-damp happened in Friar-street, in the Borough; there were, happily, no lives lost, though the shock of the explosion was felt at a considerable distance round the neighbourhood. The cast-iron plates, covering the man-holes in the flag-pavement in Friar-street, were all blown into the air, and flames came through the gully-gratings into the streets. It appears that the sewer in Friar-street has been in a most pestilential state for some time, and cholera is prevailing immediately around it to an alarming extent. Notwithstanding repeated complaints had been made, nothing had been done by the Commissioners, and on Saturday Messrs. Anderson and Cally, soap-boilers, were prevailed on by some of the inhabitants, in despair, to attempt to draw off the pestilential vapour by connecting a pipe from the sewer with one of their chimneys. All went on apparently well for about half an hour, when the explosion occurred.—[We cannot wonder that fatal diseases should prevail to a great extent where the sewerage and drainage are so defective. With the cholera in our midst, entailing Herculean labours on the members of the Medical Profession, the non-medical officials in the Metropolis, appointed to carry out sanitary improvements, have done little or nothing for good. The foul sewers of the Metropolis are sources of most malignant diseases, for, as we learn from what has taken place in Friar-street, such noxious gases are generated, that if not allowed continually to escape they accumulate to such an extent that the slightest circumstance is sufficient to cause them to explode.]

The Commissioners of Sewers and Mr. Simon.—The diligence and faithfulness of the City Medical Officer of Health and the staff under his superintendence, do not appear to please some of the Commissioners; and a Mr. H. L. Taylor, on Tuesday last, complained that Mr. Simon had depended for his information not upon what he had himself observed, but upon the statements of parties with whom the Corporation had nothing to do, who ought not to be recognised, and whom he was sorry to see encouraged. This wise gentleman, we suppose, imagines Mr. Simon to be ubiquitous, or that he possesses as many organs of vision as Iris, and as many arms as the far-famed Briarius. The Officer of Health alone could not detect and expose all the nuisances of the City; hence he has properly associated with him a number of Medical men. The fact is, that the exposures which these have recently made, have offended Mr. H. L. Taylor, and others of whom he is the representative. We hope, however, that Mr. Simon and his coadjutors will continue fearlessly to expose and denounce whatever they find in the City calculated to injure the public health.

Presentation of a Testimonial.—It affords us much gratification to record instances of public respect paid to the members of our Profession, for the faithful and efficient discharge of their duties. No class of men make greater sacrifices for the benefit of others than Practitioners of Medicine. Yet it is singular, that while on the Continent Governments have occasionally rewarded them with titles and pensionary gifts, in our own country the Medical Profession is almost entirely overlooked by the Executive, and the public too frequently think their services rewarded by a small fee. We are glad to mark indications of a better state of things, and more especially do we rejoice that the poor are taking the lead in paying public respect to their Medical attendants. An instance of this kind occurred about a fortnight ago at Kingswood, near Wotton-under-Edge, where a public meeting was held in the school-room, for the purpose of presenting to Mr. W. J. Hill, surgeon, of Wotton-under-Edge, a very handsome silver salver, together with a purse of sovereigns, as a testimonial of gratitude to him for his unwearied and successful exertions during the recent prevalence of the cholera, especially in his gratuitous professional attendance on the poor. This testimonial originated in the grateful feelings of the working men, and was completed by their persevering exertions. Several of them spoke on the above occasion in a manner which did equal honour to their heads and hearts. The Rev. G. S. Weidemann, incumbent of the parish, presided on the occasion. The salver cost 25*l.*, and bore the following inscription:—"Presented to William James Hill, surgeon, by the inhabitants of Kingswood, as a token of respect to him for his benevolent, unremitting, and gratuitous exertions during the prevalence of the cholera. A.D. 1849." About 300 persons were present.

Irish Peat Charcoal and the Sanitary Reform of London.—On Monday evening last, an important meeting was held at the Rooms of the Mechanics' Institute, Southampton-buildings, Chancery-lane, on the invitation of Mr. Jasper W. Rogers, to witness his process for deodorisation and consolidation of the fetid liquid mass of the sewers of London, which has lately materially assisted, if it has not originated, the fatal cholera. The meeting consisted of about 500 persons, among whom were some of the most scientific men in London, and several foreigners from Paris and elsewhere. The day fixed being that on which most of the inaugural addresses were delivered at the London Hospitals, after which the members dine together in Hall, many scientific men were prevented from attending, who expressed their regret through parties who were present. The plan adopted by the meeting for testing the principle advocated by Mr. Rogers, was the time-hallowed one of "trial by jury." A chairman was selected at hazard, and of the eight jurymen "summoned" by the meeting, only one was personally known "to the prisoner." Dr. Alfred King, 21, Lower Calthorpe-street; Mr. Lyon, Secretary to King's College Hospital; Mr. Griffith, surgeon, 1, Bloomsbury-place; Mr. T. A. Yarrow, C.E., Cheshire, and 18, Adam-street; Mr. Nesbett, accountant, Winchester-house, Old Broad-street; Mr. D. Walker, M.A., Maidstone College; Mr. Swinburne, barrister, 11, South-square; Mr. G. Garnett, 130, Jermyn-street, Commissioner of Paving; Mr. Nesbit, analytical chemist, Agricultural Academy, Kennington—were the parties empanelled. The investigation was proceeded with, most cautiously and critically, and the materials weighed before and after the experiment. Bags containing samples of the apparently dry deodorised matter were also freely circulated among the spectators. The jury delivered their opinions *seriatim*, resulting in an unanimous opinion that Mr. Jasper Rogers had fully demonstrated his proposition, and that the experiment had been most eminently successful. Several of the jury stated that they had come to the meeting, aware of a portion of the principle as appertaining to animal charcoal, but sceptical as to the results predicted by Mr. Jasper Rogers with peat charcoal. On Mr. Rogers presenting himself to the meeting after the verdict, he was most enthusiastically cheered, and was highly complimented on the fairness with which his experiments had been conducted.

English Gratitude.—A few days ago, a medical man was passing through the Quartier St. Germain, in Paris, when he was attracted by a crowd, in the midst of which he found a poor Englishman smitten by an attack of apoplexy. He hastened to

render him the assistance that medical aid could afford. The next day the medical man called upon his patient to inquire how he felt. The Englishman asked him what he was to pay. The doctor replied ten francs for two visits, at five francs each. "Oh," cried the Englishman, "my life is worth more than that;" whereupon he handed the physician a cheque for 500 francs.—*Paris Paper.*

PRUSSIAN MEDICAL STATISTICS.—In Prussia the population is 16,110,000; and there are 5,137 civil physicians, 351 military physicians, 827 surgeons of the first class, 1,144 surgeons of the second class, 1,423 apothecaries, and 11,539 *female* midwives.

THE PROFESSION IN TURKEY.—The so-called *barbarous* Government of the Sublime Porte actually pay their medical men. The duty of those who thus receive salaries from the State, is to visit both the rich and the poor, or to receive them at their own abodes; they are to accept no fees from the poor, and are punished if they confine their practice to the rich. Every three months they are obliged to furnish to the constituted authority certain statistic accounts of the number of their patients, the nature of their cases, and the results of the treatment; the history of epidemics, and the observed meteorological phenomena. The regulations concerning interments without the city, are such as ought to put to shame nations who are given to boast of their civilization.

EGYPTIAN OPHTHALMIA.—Dr. Pruner attributes the frequency of ophthalmia in Egypt—1st, to ammoniacal exhalations from the earth; 2ndly, to the irritating nature of the sands of the desert; 3rdly, to the unequal distribution of light in the houses and in the streets; 4thly, to the sudden alternations of temperature.

THE PLAGUE.—The *Gazette du Midi* of the 15th, contradicts a rumour which had been afloat at Marseilles, that the plague had made its appearance first at Fiume, and afterwards at Trieste. No intelligence of the existence of the malady on the shore of the Adriatic had been received at Marseilles, either by the Consular body or the *Intendans de Santé*. What has given rise to the report, is the appearance, in a village near Fiume, of a disease called scarluppo, a sort of cancer which attacks the face, and which the people of the country call plague. The horror inspired by such a malady causes a sanitary cordon to be established, and by that means it does not go beyond the locality where it first breaks out.

MORTALITY TABLE,

(Metropolis.)

For the Week ending Saturday, Sept. 29, 1849.

CAUSES OF DEATH.	Total.	Average of Five Summers.
ALL CAUSES	1611	1008
SPECIFIED CAUSES	1607	1005
Zymotic (or Epidemic, Endemic, and Contagious) Diseases	782	302
SPORADIC DISEASES:		
Dropsy, Cancer and other Diseases of uncertain or variable seat	46	44
Tubercular Diseases	167	190
Diseases of the brain, Spinal Marrow, Nerves, and Senses	114	119
Diseases of the Heart and Blood-vessels	48	29
Diseases of the Lungs, and of the other Organs of Respiration	128	81
Diseases of the Stomach, Liver, and other Organs of Digestion	58	76
Diseases of the Kidneys, &c.	7	11
Childbirth, Diseases of the Uterus, &c.	11	7

TO CORRESPONDENTS.

The business of a new session, and our Student's Number last week; the admirable discourse delivered by Professor Walshe at the opening of University College, and that of Professor Farre at King's College, have thrown us much out of our usual routine; we trust, however, not unwisely nor unprofitably. The lectures of Professor Owen, of Mr. Walton upon the Eye, of Dr. Letheby, and Dr. Budd and Professor Quain, and our edition of Dieffenbach's Operative Surgery, have all necessarily stood over, we fear much to the disappointment of many of our readers. We, however, hope next week to return to our ordinary course, and to continue in it regularly.

"Dr. Dickson."—We have received a letter from Dr. Dickson, and this we had intended to publish as the latest fallacy of the fallacious author of the "Fallacies of the Faculty." We are advised, however, that the language of Dr. Dickson's note is such as to be grossly libellous *upon himself*; and that he might sue us for damages did we give it publicity. For his sake, therefore, we have afforded it the next warmest reception in our power,—the fire. We inform Dr. Dickson, however, that the gentleman to whom he alludes, had as little to do with our article on the "Philosophy of Epidemics," as he himself with the views which he claims as his own.

"Medicus."—We have had our attention directed to the "difficulty" to which our Correspondent refers. The order of the Board of Health is, that "advanced medical students be appointed to give up their whole time to a regular and careful house to house visitation throughout the several districts of the city of London Union, if legally qualified medical men cannot be obtained for the service." We do not see any impropriety in this order; for it would be far better for "advanced medical students" to have the care of Cholera patients, than that they should be left to die without aid. Neither can we suppose that the Apothecaries' Company, under the circumstance, would interpose its authority to prevent the carrying out of such an order. We think, however, that if a careful search were made, enough legally qualified practitioners may be found to meet almost any emergency.

"G. M."—(1) The apodyterium of the ancients, according to some authors, appears to have been the frigidarium of smaller establishments. Others mention the apodyterium and tepidarium as the same room, and those who bathed are said to have left their clothes in this doubly-named apartment. (2) The ancient physicians thought bathing highly conducive to health when employed under certain regulations.

"A Correspondent," who asks the way in which argent. nitras is formed into pencils, is informed, that it is by means of a mould, generally made of brass or gun-metal. This mould consists of two metallic grooved plates, joined together by screws, and the caustic, in a melted state, is poured into a cavity at the top. When the caustic has hardened the mould is unscrewed, the two plates separated, and the cylinder removed from the grooves.

"An Occasional Correspondent."—(1) It is certainly possible to mistake a case of arsenical poisoning for cholera, especially when this disease is epidemical. There are however, certain symptoms by which arsenical poisoning may be distinguished from Asiatic cholera. (2) We would recommend, in all cases where the medical attendant has any suspicion of the administration of a deleterious substance, a *post mortem* examination.

"An Old Indian Medical Officer" writes us, in reference to the discovery of Dr. Brittan, "that the cholera animalcules must not only delight in certain places, but have a particular attachment to certain persons. I have known," says our correspondent, "in India, the cholera, in a cantonment free from disease, to attack ten or a dozen men of the same regiment in one night, while neither in this, nor in the other regiments at the same station, did any subsequent case occur. I can only account for this phenomenon on the supposition, that the newly-discovered animalcules migrate occasionally, and, in their flight, sometimes attack particular individuals, passing down their throats into their stomachs and intestines, and then producing choleraic cramps and rice-water evacuations." Our correspondent further supposes that the animalcule producing cholera is a kind of very minute mosquitoe, as this troublesome little tropical insect always delights in warm, confined, and damp localities.

"Medico-Chirurgus, Liverpool."—1. The order to make a *post-mortem* examination includes a chemical analysis of the contents of the stomach, &c., and no additional fee is recoverable for such analysis. This is very unjust, as expensive processes are sometimes necessary to detect deleterious substances in the body. 2. Medical witnesses called to give evidence at a trial for manslaughter or murder are paid for attending at the trial, in addition to the payment at the inquest, a sum per day, not fixed by law; generally about one guinea a day. 3. A surgeon called by a police-officer to treat an accident on a person in a state of insensibility, has a legal claim upon the patient. If, however, the medical man is called by the police to attend a sick person at the station-house, a fee of 3s. 6d. in the day time, and of 7s., if after nine o'clock at night, is paid by the police authorities.

"A Provincial Surgeon."—1. The meetings of the Royal Medical and Chirurgical Society are held on the second and fourth Tuesday of every month, from the second Tuesday in November till the end of June. 2. The name of every candidate for the fellowship is posted in the library for a certain time. The election is, by ballot, and the fee is £6 6s., exclusive of the annual subscription. The Fellows who reside more than seven miles from London pay no subscription.

"Homo Medicalis."—Yes: the two varieties differ in their geographical distribution. The tænia solium is met with in England, France, Italy, Germany, and other countries in the south of Europe, while the tænia lata is found in the intestines of the inhabitants of Russia and other northern countries of Europe; either worm is rarely met with out of its own district.

"A General Practitioner."—The Examiners at the College of Physicians can, if they please, examine a candidate for their diploma in Latin. We should think, in our correspondent's case, that the questions and answers would be in English.

"Experimentalist."—(1) Under the microscope human blood is not easily distinguishable from that of other animals; for the globules in the mammalia are similar to each other in form and size. (2) The red globules vary even in the same individual.

"Mem."—Pregnancy may occur previous to the occurrence of the catamenia.

"A Subscriber"—A person cannot be prosecuted for practising surgery without a diploma It is necessary, however, to have passed an examination at the College of Surgeons in order for a medical man to become eligible for certain appointments.

"A Lover of Truth."—We cannot publish our Correspondent's statements unless they are authenticated.

"J. B., M.D."—The exact nature of ozone is still not ascertained. The opinions of chemists differ. Berzelius supposes that traces of oxygen are put into an allotropic or isomeric condition, in which its electro-negative character is heightened. Schœnbein considers ozone to be a volatile binoxide of hydrogen. It liberates iodine from iodide of potassium; separates peroxides of manganese from salts of the protoxide; converts yellow prussiate of potash into red; and it is removed or decomposed by contact with most organic matters.

"Adolescens."—The hydro-electric machine owes its extraordinary power to the practical construction of the nozzle of the escape-pipe. By forming its extremity with an imperfect conductor, and interposing in the path of the escaping steam a disc against which it must forcibly rub, the excitation is raised to its most intense form.

"Filius Æsculapii."—It is a disease sui generis, appearing only in tropical climates, and attacking the same individual but once.

"Guyensis."—1. The sound of the fœtal heart resembles the ticking of a watch under a pillow. 2. The best situation for its being heard is between the umbilicus and the anterior spines of the ilium, on either side.

"Mr. Eckford."—The subject is under consideration.

"Erinensis."—The license of the Dublin Apothecaries' Society confers no legal right to practise as an apothecary in England.

"Chiron."—We cannot answer the question.

"G. J. L."—Application should be made to the Secretary of the College.

"Leonard."—The fees vary.

"M.D. Edin."—We have not received the communication.

"A Young Surgeon" should send us his name and address in confidence.

"Dr. Inglis, Halifax."—We will examine the papers.

"Mr. Radcliffe, Leeds," is thanked for his communication. The subject shall be noticed.

"Chirurgus."—1. We have no faith in opium where the patient is collapsed. 2. The joint should be kept at rest till any laceration of its ligaments may have healed; the time depends much on circumstances.

"An Old Retired Physician" has mistaken our intentions. We are not prejudiced in favour of any particular treatment.

"Mr. Laseby, Islington," received.

"B., Reading."—The request shall be attended to.

"R."—It is usual for the new-comer to have the first visit paid him.

"Mr. Daniell, Newport Pagnell."—Communication received.

We must apologize to Dr. Tucker for not introducing this week his letter upon the saline treatment of cholera, and the result of his practice as medical attendant of the Sligo Dispensary. The subject is treated of at some length, and we cannot, this week, find room for it.

Dr. Dingan's communication has been received.

"An Englishman."—We trust our Correspondent's opinion as to the prevalence of Materialism amongst medical students is not correct. Although foreign to our legitimate purpose, and totally unfit for the columns of a *Medical* Journal, we afford space in our columns to Correspondents to the following remarks:—"You who write so warmly in the interests of the Students of the Medical Profession, will not, I trust, refuse to insert this short letter, calling their attention to what must be regarded as, at least, the extreme uncertainty of Materialism, a theory now not unpopular, and to which their course of study unavoidably tends. One hundred pounds reward has been offered for the last two years, by advertisement, through Mr. Churchill, the Medical Publisher of Soho, to any one who makes *the first tenet* of this theory clear; and no one has yet even tried to do so, although the amount of scientific knowledge necessary could be read up in a week or two. Is not this fact, alone, enough to make one suspect that the thing cannot be done; and how is it, I may ask, amidst the tenets I see promulgated, that men of young and energetic mind do not seek the grounds of what they believe?"

"Dr. Richardson's" Letter is in type.

Reports of the London Medical Society will appear in our next.

[Advertisement.]

His Royal Highness Prince Albert has been pleased to appoint Edwin Saunders, Esq., of George-street, Hanover-square, to be Surgeon-Dentist in Ordinary, in the room of Mr. Nasmith, deceased.

London Gazette, October 2nd.

PROFESSOR MILLER'S SURGERY.

THE PRINCIPLES OF SURGERY. By JAMES MILLER, F.R.S.E., Professor of Surgery in the University of Edinburgh. In small 8vo, containing 716 closely-printed pages, price 9s., cloth.

"An admirable epitome of the surgical science of the day."—Lancet.

"We feel no hesitation in expressing our opinion, that it presents the philosophy of the science more fully and clearly than any other work in the language with which we are acquainted."—Philadelphia Medical Examiner.

By the same Author,

THE PRACTICE OF SURGERY. In small 8vo, containing 712 closely printed pages, price 9s., cloth.

"We had occasion, in a former Number of this Journal, to speak in deservedly high terms of Professor Miller's work on the 'Principles of Surgery,' and we are happy to be able to pronounce an equally favourable judgment on the manner in which the present volume is executed."—British and Foreign Medical Review.

"We have no hesitation in stating, that the two volumes form, together, a more complete text-book of surgery than any one that has been heretofore offered to the student."—Northern Journal of Medicine.

Edinburgh: Adam and Charles Black. London: Longman and Co.

Recently published,

A DISPENSATORY, or Commentary on the Pharmacopœias of Great Britain; comprising the Natural History, Description, Chemistry, Pharmacy, Actions, Uses, and Doses of the Articles of the Materia Medica. By ROBERT CHRISTISON, M.D., President of the Royal College of Physicians of Edinburgh, Professor of Materia Medica in the University of Edinburgh, and Ordinary Physician to the Queen for Scotland. A New Edition, revised and improved, with a Supplement containing the most important New Remedies which have come into general use since the publication of the last Edinburgh Pharmacopœia. In one thick volume 8vo (1000 pp.), price 20s., cloth.

"We earnestly recommend Dr. Christison's 'Dispensatory' to all our readers, as an indispensable companion, not in the study only, but in the surgery also."—British and Foreign Medical Review.

"The most accurate, the best arranged, and cheapest work of the kind."—London and Edinburgh Journal of Medical Science.

By the same Author,

A TREATISE ON POISONS, in relation to Medical Jurisprudence, Physiology, and the Practice of Physic. Fourth Edition. Enlarged, Corrected, and Improved. In one thick volume 8vo (986 pp.), price 20s. cloth.

"An examination of the whole will convince the reader that this is a standard publication; one of the most valuable and necessary which he can place in his library."—Medico-Chirurgical Review.

"Dr. Christison's great work on Poisons, by far the best on Medical Jurisprudence in our language."—Blackwood's Magazine.

"One of the greatest additions that has been made to the stores of medical and especially of medico-legal literature." Buchner's Repertorium.

By the same Author,

A TREATISE ON GRANULAR DEGENERATION OF THE KIDNEYS. In 8vo, price 8s., cloth.

"The illustrative cases, thirty-one in number, are narrated with Dr. Christison's usual clearness, and, like the rest of the work, are highly instructive. We strongly recommend this book to our readers."—London Medical Gazette.

Edinburgh: Adam and Charles Black; London: Longman and Co.

YEARSLEY ON DEAFNESS.

This day is published, price 5s., cloth, 8vo,

DEAFNESS PRACTICALLY ILLUSTRATED, being an Exposition of Original Views as to the Nature, Causes, and Treatment of Diseases of the Ear. By JAMES YEARSLEY, Surgeon to the Metropolitan Ear Institution, Sackville street.

"A careful perusal has convinced us that the Author is correct in his views; his experience has been ample, and his powers of observation and research have been by no means inferior to his opportunities."—Medical Gazette.

"A thorough acquaintance with the facts and views which it contains must be regarded as essential to the medical practitioner."—Lancet.

"Contains much practical information." — Medical Times.

"Well deserving attention."—British and Foreign Medico-Chirurgical Review.

"The Author's observations will be read with advantage, and will afford many useful hints for the detection and management of disease."—Prov. Medical Journal.

London: John Churchill, Princes-street, Soho.

DR. RAMADGE ON ASTHMA AND DISEASES OF THE HEART.

One Vol., greatly enlarged, second edition, 10s. 6d.,

ASTHMA; its Varieties and Complications, with Practical Remarks on the Specific Treatment of each. Illustrated by Cases, and Plates coloured from Nature; to which is annexed, a Succinct Treatise on the Principal Diseases of the Heart. By F. H. RAMADGE, M.D., Fellow of the College of Physicians, late Senior Physician to the Royal Infirmary for Asthma, Consumption, and other Diseases of the Lungs.

London. Longman and Co.

Just published, in one quarto vol., price Half-a-guinea, with a Frontispiece, on stone,

THE PHYSIOGNOMY OF DISEASES. By GEORGE CORFE, M.D., Resident Medical Officer of the Middlesex Hospital.

James Nisbet and Co., 21, Berners-street, Middlesex Hospital.

THE CONSPECTUS OF FIVE PHARMACOPŒIAS, comprising all the Preparations authorized by the Colleges of London, Dublin, Edinburgh, and the United States; with the Paris Codex; enriched with elucidatory notes, and references to the works of Christison, Pereira, Ure, Brande, Turner, Liebig, Soubeiran, Phillips, Collier, &c., may now be had, stitched in a neat cover, price 2s. 6d. May be had of all Booksellers; or will be sent by post, free, on receipt of 3s.

Wm. S. Orr and Co., 147, Strand.

Royal 8vo, cloth 18s., and morocco, 28s.,

MILNER'S GALLERY OF NATURE; a Pictorial and Descriptive Tour through Creation, Illustrative of the Wonders of Astronomy, Physical Geography, and Geology, with 16 Engravings on Steel, and many hundred Vignettes and Diagrams.

London: Wm. S. Orr and Co., Amen Corner, and 147, Strand.

WORKS BY W. B. CARPENTER, M.D., F.R.S.

ANIMAL PHYSIOLOGY; including a Comprehensive Sketch of the principal Forms of Animal Structure. By W. B. CARPENTER, M.D., F.R.S. With several Hundred Engravings on copper and wood, drawn under the direction of M. Milne Edwards, for his "Cours Elementaire de Physiologie." 8vo. Cloth lettered, 6s.

ZOOLOGY, and INSTINCT in ANIMALS; a Systematic View of the Structure, Habits, Instincts, and Uses of the principal Families of the United Kingdom, and the Chief Forms of Fossil Remains. 8vo. In 2 vols., cloth, lettered, 12s.

MECHANICAL PHILOSOPHY, ASTRONOMY, and HOROLOGY. An Exposition of the Properties of Matter; a Description of the Heavenly Bodies; and the Construction of Instruments for the Measurement of Time. 8vo. Cloth lettered, 6s.

VEGETABLE PHYSIOLOGY and BOTANY; including the Structure and Organs of Plants, their Characters, Uses, Geographical Distribution, and Classification, according to the Natural System of Botany. 8vo. Cloth lettered. 6s.

Wm. S. Orr and Co., Amen-corner, and 147, Strand.

Dr. Sandifort's Library.—The celebrated Medical Library of that eminent Physician will be SOLD by AUCTION, on October 29 and following days, at Leyden.

The Catalogue, price 2s., may be had of Williams and Norgate, 14, Henrietta-street, Covent-garden, London.

The Breast-Alleviator. Thier's Patent. EDWD. LANE, 13, John-street, Adelphi, Sole Licensee.

The attention of the Profession is solicited to the above invention, the action of which is entirely novel, and closely resembles the natural sucking of the child. Where artificial means are required, it relieves the breast, without pain, while, at the same time, the infant can imbibe the milk. To be obtained at 35, Warwick-street, Regent-street, London; or may be seen at the office of the Licensee, as above.

Pyretic Salts.—The Profession are informed, that the true ones, containing the salts present in the blood when in a healthy state, and strongly recommended by gentlemen having charge of the cholera patients, may be OBTAINED through their usual DRUGGIST. They supply the system with saline fluid, the deficiency of which, with electro-atmospheric changes, are the predisposing cause of cholera and typhus. (One teaspoonful, given with two drachms of the chloride of sodium, in half a tumbler of water, or combined with chalk mixture and ammonia is the dose. Repeated every two hours, if needful.)

Prepared by H. Lamplough, 68, Snow-hill, London.

The success of the saline treatment will be noticed by the Journals. Communications to that effect are requested.

Tarrant's Bandage and Strengthening Plaister.—This Plaister, from the nature of the composition and the material on which it is spread, is adapted for a permanent bandage, as it neither produces irritation of the skin, nor, when applied, does heat cause it to lose its adaptation to the part. Having these qualities, it is peculiarly valuable in the treatment of ulcerated legs, varicose veins, &c., where equal and constant support is required. Several of the most eminent surgeons continue to use this Plaister in their practice, preferring it, in certain cases, to any other; it is well suited for exportation to, and use in, warm climates, the high temperature having less effect on it than on any other plaister.

The Profession are referred to Messrs. Westwoods and Hopkins, Wholesale Druggists, Newgate-street, where the Plaister may be had in packets, containing three yards, for 2s. 6d., or spread upon skins of chamois leather, at 3s. 6d.

Westwoods and Hopkins also call attention to their Compound Adhesive Plaister, for fractures and wounds; as likewise to their Concentrated Preparations, Essences, &c.

ORIGINAL LECTURES.

ON SOME OF THE CIRCUMSTANCES WHICH HAVE RETARDED THE PROGRESS OF MEDICINE.

AN INTRODUCTORY LECTURE, DELIVERED AT KING'S COLLEGE, LONDON, ON OPENING THE MEDICAL SESSION OF 1849—50.

By ARTHUR FARRE, M.D. CANTAB., F.R.S.; Professor of Midwifery, King's College; Physician for Diseases of Women and Children; and Physician Accoucheur to King's College Hospital.

MR. PRINCIPAL AND GENTLEMEN,—Among the various duties which have heretofore devolved upon the Dean of the medical department, not the least agreeable has been that of receiving you here, on occasions like the present, with that cordiality of feeling which it has ever been the desire of the professors to promote between themselves and their pupils.

This welcome task has of late years been undertaken by the Dean of the year; but it having been determined that the office of Dean of the medical department shall become a permanent, instead of an annual one, we have now returned to our former practice of affording to each professor in rotation the privilege of assembling you here, and of addressing you on matters relating to your common interests.

The occasion is one which gives opportunity for choice from so wide a range of subjects, that it is difficult to decide in what manner and of what materials an hour's discourse may be best composed.

But, in considering how I could best fulfil the duties with which I am this day charged, I have come to the conclusion that no better subject could be chosen than one that should have reference to the improvement of our Profession. And as what Lord Bacon has observed of medicine in his time, may be safely averred of it now, "that it can never be improved until its imperfections are pointed out," I propose as a subject, "The consideration of some of those circumstances which, especially in our times, have contributed most to retard the progress of medicine."

Men are much divided in opinion as to the rank which medicine ought to hold among the various departments of knowledge. Some consider it entitled to rank as a science; others view it only as a conjectural art; while most, seeing how closely it borders upon the neighbouring sciences, and how much it draws from their principles and discoveries, agree to accord to it the title of an imperfect science, and, speaking of it in conjunction with the art, designate it the Science and Practice of Medicine. In these terms are included *all* the branches of the healing art; and in this sense I wish to be understood as employing them throughout this discourse.

Now, let us for a moment examine the claims which medicine has to any or all of these titles. And for this purpose, without at all intending to waste your time or attention by entering upon matters of early history, which the curious may prosecute for themselves, allow me for a little while to direct your mental vision back into the gloom of some twenty-five or thirty centuries, and let us see how medicine then stood.

In the Asclepiæ, or Temples of Health, presided over by the order of Priest Physicians, medicine, in its origin and early progress, could be no other than a simple art—deriving no aid whatever from science—existing, in fact, before science dawned, or authentic history began.

What r[illegible] measures were adopted in these temples we have but limited means of accurately ascertaining. We know, however, that certain exercises and ablutions were practised; that attention was, to a certain extent, paid to dietetics, and that not only were the effects of medicines carefully noted down, but the symptoms and issue of every case accurately recorded by the Asclepiadæ, who became, by these means, great adepts in the art of prognosis.

Such were the Temples of Health; and from one of the most important of these sprang the Coan Sage, to whom the combined suffrages of all succeeding generations have agreed in according the title of "Father of Medicine." And well does that title appear to have been deserved, when we consider what Hippocrates did for medicine. Witness his works on Epidemics and Prognostics—the former abounding in most accurately recorded cases; his admirable remarks on diet and its relation to medicine, and his observations on air, water, and localities, in reference to health.

Now, it has often puzzled learned men to explain how, from the darkness which appears to have preceded the birth of Hippocrates, so much light should have been suddenly shed on the path of medicine by one man's efforts alone. But this wonder applies in no greater degree to Hippocrates than to any other mighty genius whose appearance constitutes an era in history, and serves to shed lustre upon succeeding generations.

It must be remembered, too, that Hippocrates was instructed in polite literature and philosophy of the age by men of classical celebrity. He enjoyed free access to all the treasures of observation collected in the Temples of Health during many generations, and the period of his existence was one of the most memorable epochs in the intellectual development of the human race. He had for his contemporaries, Pericles, the famous statesman; the poets Eschylus, Sophocles, Euripides, Aristophanes, and Pindar; the philosopher Socrates, with his distinguished disciples Plato and Xenophon; the venerable father of history, Herodotus, and his young rival, Thucydides; the unrivalled statuary, Phidias, with his illustrious pupils; and many other distinguished names, which have conferred immortal honour on the age in which they lived, and exalted the dignity of human nature (a.)

Hippocrates is, indeed, accused by Celsus, of having separated medicine from philosophy. But in so doing, when we consider what the philosophy of those days was, we see that he could not have rendered medicine a greater service. For "philosophy, whilst it had freed medicine from the delusions of superstition, had substituted the errors of hypothesis in their place. And the important office, which the father of medicine conferred upon the art was, that setting aside *à priori* arguments, and looking only to facts, he discarded both superstition and hypothesis, and substituted the results of actual observation in the room of both. Thus, at least, he attempted to place medicine upon a philosophic basis.

I need not carry you through the intermediate periods of history to show you in what way medicine has either advanced or fallen back in proportion as it has adhered to, or receded from, the ground upon which Hippocrates endeavoured to place it. How it has now degenerated into an art, now struggled to emerge into a science. To the latter title, I have said, it now often claims to be exalted. But it can approach this desirable point only in proportion as its observations and reasonings are conducted in the true spirit of philosophic inquiry. All its observations must be observations of facts; its conclusions must be fair and legitimate inductions. But, what is a fact in medicine? and what is an observation? To the different interpretations which men have put upon these questions, may be traced, in a great measure, the impediments which medicine has hitherto, and especially in our own times, suffered. *Now these impediments, we shall find, are attributable partly to the nature of the subject, partly to the erroneous modes in which men too often set about acquiring a knowledge of medicine, and partly to the mode in which the public view and receive it.*

And first, let us inquire, what is there in the nature of medicine which prevents it from being placed upon an equality with the strict sciences—notwithstanding that it is of far higher antiquity than many, if not all of them, and that so many men of the highest eminence, and distinguished for their intellectual endowments, have given up their lives to its cultivation? The reply to this question, in the first place, is, that the subjects with which medicine is conversant do not admit of the same mode of treatment, nor do they afford the same opportunities and facilities for observation and experiment that are offered by the other departments of natural knowledge.

Whoever seeks to apply *too strictly* the method of philosophic induction to the study of medicine, will find himself often greatly disappointed in the result. Nor can it fail to be otherwise. For let us consider the difference in the materials for observation, and the mode in which they are presented to our notice, in medical, as compared with other investigations.

In medicine we cannot select our opportunities for observation, but must take them as they arise. So that, do we desire to note a particular fact, we may wait a dozen years, nay, a whole lifetime, before the desired object presents itself to our expectant view.

Again, when we would begin our experiments or observations, we find that we cannot witness the entire process, but only portions of it—so that much is necessarily left to conjecture. In this respect physic requires a very liberal, active, and penetrating genius, because the observer, being often obliged to confine himself to simple probabilities, will be unable, without an extreme share of penetration, to trace them to their highest degree.

Further, we cannot deal with *animate* in the same way that we do with *inanimate* matter—for neither is it subject to the same laws, nor is it amenable to the same modes of treatment; nor can we take it under our own control, since it is governed by certain vital processes, of which, it must be confessed, we are mainly ignorant, and is further under the influence of mind, which refuses to yield itself to man's government.

Such, then, from the nature of the subject, are some of the circumstances that must, for the present at least, prevent the pursuit of medicine as a science, from being conducted upon the same rigid principles of philosophic inquiry, which we elsewhere apply with so much success. Yet it is from this very uncertainty that those who practise medicine successfully, claim their greatest honour. "For where there is no possibility of error, no praise is due to the judgment of what is right."

But this does not constitute the greatest impediment to the advancement of medicine as a science. I need not, therefore, longer dwell upon this point, but proceed to consider the next source of impediment, as consisting in the faulty mode in which men too often set about the acquisition of medical know-

(a) Works of Hippocrates, by F. Adams, LL.D. Vol. I. Sydenham Society.

ledge. And now permit me to vary in some degree the tenor of my argument, for as I have in view the offering of useful advice, rather than the binding myself too strictly in the trammels of a logical discourse, I shall, while I touch occasionally the errors to which I have alluded, occupy your time also with the consideration of the means by which these errors may be best avoided.

I begin, then, with what mainly concerns you now—with your present studies and immediate employments. And first, let me remind you of the warning aphorism of Hippocrates:—"Life is short—Art long," is the exordium of the father of physic.

But if an entire lifetime is so short, compared with the period requisite to mature and perfect any art, as to justify the remark in reference to medicine, that "it must be regarded rather as the child of Time than as the offspring of Genius," how important is it for you who are able to give, it may be only three or four years to the cultivation of that knowledge which it has required so many centuries to amass, to spend that short period to the greatest advantage. To arrange for yourselves at the very outset such well-considered methods of study as will enable you to take full advantage of the very large opportunities here afforded to you.

It is true that a certain course of study is marked out for every one, varying according to the period of time which is to be devoted to this purpose, and the nature of the qualifications which it is in view to obtain. To a certain extent, also, attention to the subjects after a given order, is made in a measure compulsory upon all—and so far little is left to your own choosing. But remember that this is but fixing the outline or boundaries of the work which, during the status pupillaris, you are called upon to perform. The manner of the performance, so that it does but exhibit a sufficient degree of attention, and desire for learning, is all your own.

Do not, however, missapprehend me. Let no one suppose that it is a matter of indifference to the professors of the several departments whether their pupils acquire little or much knowledge. On the contrary, you will find that by every available means, whether of example, of advice, or of friendly warning, your teachers will endeavour to urge you on to the full and profitable employment of that time, which, if now misspent, can never afterwards be regained.

But here let me give you one caution regarding lectures. The student who relies upon lectures alone will find himself but very imperfectly instructed in his profession. For their true use and aim is not so much to teach, as it is to point out to him what he ought to learn. To lead and guide, but not to constitute his studies. To draw him on by well-considered steps from one subject to another, smoothing the difficulties, simplifying and preparing the way for those more difficult modes of study, with which he is afterwards to be engaged,—but not supplanting them.

But to make your courses of study fully serviceable to you, there must be also discipline; and without discipline, we do not profess to offer you instruction. Now, it is of the first importance that you should have a right comprehension of your duties in this particular, both with regard to your teachers and also to yourselves.

Discipline, to a sensible man, never means control. He sees in it only that order and regularity which are established for the general good, and in which each member of the community is proud to take a part. I need not dwell upon the details of such matters, because the more immediate superintendence of them will devolve upon the permanent Dean, Dr. Guy, whom you must regard as, what I am sure, indeed, you will find him, your counsellor, adviser, and kind friend. Every one, then, who enrols himself as a student of this College, gives thereby an implied compact that he will abide by its customs and regulations.

And we deem it no unreasonable expectation that he should make *these* matters of prime consideration,—that he should lend himself heartily to the work of duly fulfilling the course and order of the studies upon which he has entered,—and that in all this he should exhibit the conduct and bearing of a Christian and a gentleman. Nay, more, are we not justified in expecting that no inconsiderable number will leave a lasting memorial of their residence here, by adding themselves to the number of those distinguished students whose names we are proud to recount as shedding lustre upon this, the home and seat of their instruction.

If, gentlemen, this praise rested upon no othe[r] evidence than that which the records of the Colleg[e] alone afford, we might be accused of partiality fo[r] those whose education it had been our occupatio[n] and pleasure to direct.

But there are some who have also distinguishe[d] themselves before other tribunals,—and to those w[e] feel that we have a duty to perform, and no unwel[come] one it is! The duty of publicly expressing ou[r] gratification at seeing our Alumni heading the lis[t] in the struggle for University honours and dis[tinctions].

No inconsiderable cause for gratification is it to find that, in the last examination for medical honour[s] in the University of London, the whole of the firs[t] gold medals, four in number, and both the exhi[bitions], were obtained by two King's College men.

Gentlemen, we do not hesitate to hold up to yo[u] Charles Pardey and George May, as men whos[e] success may well stimulate your exertions; and i[f] your desire is also to maintain the character o[f] King's College, we can offer you no better advice than that you should "go and do likewise."

Now, as I have ventured to recommend discipline in regard to conduct, let me also advise you i[n] reference to the equally important subject of discipline in regard to mind,—that training of the intellect which every one of you who expects to excel in his profession must impose upon himself. "If ever it is of advantage to think rightly, it is so at your age, when the mind is fresh and ductile. Postpone this discipline, and time will bring with it changes from which you will not be exempted. It will bring with it rooted prejudices, and modes of seeing things after your own ways; your position in life, and your associations, will give a colouring to events; and you will find that you have not escaped the thraldom of habits, but have only acquired inefficient ones; that your mind has been moulded by circumstances, instead of by principles; that your views of science and scientific advancement are oblique; that your laborious industry is unproductive, because immethodically or falsely exercised—and that your years have slipped away without enriching the intellectual stores which were entrusted to you;" (a) you have been

"Lowering buckets into empty wells,
And growing old in drawing nothing up."

But I must revert to more practical studies. Those in which, ceasing to be listeners or mere spectators, you enter upon a more practical part of your career, and become yourselves in a measure the actors in the scene of your studies. And, first, let me speak of *Anatomy*,—the neglect of which has, in my opinion, contributed more than anything else to retard the progress of medicine. I do not speak here of present neglect, for anatomy never was so extensively or so highly cultivated as it now is; but I refer to past times, even up to a comparatively recent period, when dissection was very little regarded, and when morbid anatomy was only beginning to be cultivated, and microscopic anatomy was unheard of and unknown.

Contrasting those times with the present, we cannot help regarding microscopic investigation as constituting the most interesting feature of the day. But how slow was the Profession in general to admit this as a legitimate means of investigation; nay, so general at first was the dislike, or rather, I may say, jealousy of this method of observation, that a medical man who was provided with a good microscope really felt that he had a somewhat dangerous possession, and was compelled to be cautious how he employed it, lest it should be thought that he was departing from the duties which he owed to his Profession.

The opposition, however, which the microscope had to encounter was no greater than other useful inventions have been fated to struggle against, before they have passed into general employment. It rested upon no stronger basis than the occasional deficiencies of bad instruments, and the errors of incompetent observers. Time soon corrected both of these, and the thirst for knowledge excited by the exquisite appearances revealed by the microscope, was fostered and kept alive by the rapid improvements in the instrument—the observer and the artist mutually entering into an honest rivalry, and endeavouring to outstrip each other; the one, in finding objects of such surpassingly delicate organization as to baffle the efforts of the optician to define; the other, in bringing his glasses to such unrivalled perfection, as to open the field anew to the keenest and most practised observer.

Now this was no vain and profitless contest. It could not fail to have its beneficial effects; for whilst every new discovery in minute anatomy added to our stock of knowledge, in a field hitherto uncultivated for any useful purpose, the voice of opposition became so rapidly silenced, that in the course of a few years it has literally died away. The turning point of this desirable change may in no inconsiderable measure, I think, be traced to the formation of the Microscopical Society—a society which, founded by one of our own profession, was no sooner established than it was joined by between 100 and 200 members, many of whom belonged to medicine.

Gentlemen, I have a very strong feeling with regard to the value of microscopic investigation. I believe that it will prove to be even in our day the most powerful auxiliary that has ever yet been afforded to medical research—that it will do as much, or even more, for medicine, than the telescope has done for astronomy. Indeed, the cases are nearly parallel. In both, there is a region which lies beyond the power of unaided vision. The one apparently as infinite in space, as the other is in minuteness. Into these regions it has pleased the Almighty Author of nature to permit us to penetrate, and there to regale our delighted vision with new proofs of his omnipotence. Nor can we view this permission as having been given for any other than the highest purposes—to stimulate man's curious, searching spirit—to give a keener edge to his inquiring inclinations—to shower on every step by which his ingenuity advances, the reward of a thousand beneficial discoveries—to crown his efforts by extending his usefulness to man—to lead his soul to the contemplation of his God.

If any or all of these be motives, let nothing deter you from the inquiry after truth. If the wit of

(a) In[illegible] Lecture by Robert Ferguson, M.D. [illegible]

man has gained for his limited faculties a new accession of power, be sure that nothing but prejudice can oppose its employment. Use, then, these new powers "for the benefit of man," apply them to the purposes of your profession; endeavour to search out and unravel by this new aid the intricacies of our organism; examine it in health and in disease probe the sources of its maladies, and seek to discern the elements that tend to its destruction. In this way only can you hope to advance our knowledge of morbid processes and morbid changes; and, as far as anatomy and physiology are concerned, to place your profession upon a surer and wider foundation

But, gentlemen, whilst a new impulse has thus been given to anatomical investigation, by the discovery and application of more efficient means of research, and whilst a new responsibility rests upon us for their due employment, we must not make our brethren in the ages immediately preceding ours altogether chargeable with the consequences that have resulted to our profession from the imperfection of anatomy; because a very little reflection and inquiry will show, that even up to our own times anatomy has greatly suffered from causes extraneous to the profession, some of which must indeed always operate more or less forcibly to the prejudice of anatomical investigation, inasmuch as they are inseparable from the influence of the finer attributes of our nature.

I cannot altogether quit this subject without alluding to a circumstance just now of peculiar interest. Our land is being swept by a pestilence which has already carried away many thousands of victims, not sparing our own ranks. How has science exhausted its highest efforts in endeavouring to determine the source and nature of this plague! How has ingenuity been constantly occupied, yet failing at all points in discovering a remedy! Now, however, we seem to be arriving at some views which may be found to throw a complete light upon the first, at least, of these requirements. I need not, perhaps, more specifically allude to this very recent discovery, as many of you may be aware of its nature, than by saying, that with the aid of the microscope, certain corpuscles have been observed in the excretions and bodies of those who have died of cholera, and also in the air and water of cholera-infected districts. These, as far as investigations have yet proceeded, appear to be peculiar to the localities and subjects of the epidemic. Now, to say more than this at present would be to overpass those strict boundaries which the laws of scientific investigation impose upon observers. We must yet wait for further confirmation of these most interesting observations, before we receive them as acknowledged and undoubted truths. Tested, however, as they have been, by most competent observers, they come to us with a force which compels our earnest attention; and, should these observations tend to an explanation of the real nature of the disease, as I think they may, the discovery will be one of the most interesting and important events that has ever occurred in the history of medicine.

The records of epidemics constitute, perhaps, the most valuable portion of our annals; but where shall we find any account that has hitherto explained, in a satisfactory way, the exact cause of these fearful visitations? The ancients ascribed them to the anger of their gods; but sought for no explanation of a physical nature. In our day, whilst we acknowledge and bow before the hand that directs the scourge, still, stimulated by the desire of doing good, and of employing, to the highest extent, those faculties with which we have been blessed, we hesitate not in our endeavour to penetrate the dark secrets of nature, and there to seek an explanation of the malady which has afflicted us.

But, let us not hastily conclude, that, should these prognostics prove true, we have now, for the first time, received a physical explanation of phenomena, in which we still acknowledge a yet higher source. Should any one doubt the propriety, or even probability of such an explanation as that which is now offered, let me invite his attention, or rather his recollection, to those fearful demonstrations of Divine vengeance which the *most* ancient of histories records; and there trace, in those handfuls of ashes, which, sprinkled towards heaven, in the very sight of the offending monarch, became a fine dust, penetrating to *some* portions of the land, yet sparing *others*, the intelligible instruments by which an epidemic may be swayed.

And now let me follow you to the hospital, and see how you will acquit yourselves in this new field of observation. What a vast source of knowledge is now opened up to you! All that you have yet learned is but ancillary to what you are now beginning to investigate. I speak, therefore, no longer of previous studies, of lectures, or demonstrations, or dissections; the first object of these is accomplished when you have acquired sufficient knowledge to guide you to the investigation of disease.

And to this investigation you will, indeed, find all your previous acquisitions necessary; Anatomy Physiology, Pathology, Chemistry, Materia Medica, Botany. But why attempt the enumeration? These, and all that you have learned in lectures, of the principles and practice of the healing art must now be applied to the business of studying disease, not as heretofore, in the abstract, but now with tangible and living examples of what you have before been only mentally contemplating.

And which of these examples will you select for the commencement of your studies? What class of cases shall first occupy your attention? These are matters which you may decide for yourselves. Do you make Surgery your chief object? You will then probably commence in the wards devoted thereto. Or does medicine claim your first attention? There will be no lack of cases to supply your wants.

But these are not the points upon which I would address you. I regard medicine, whether clinical, surgical, obstetrical, or forensic, as one science, to be studied only in one mode; and it is upon the right mode of studying, rather than upon the particulars, or details, or order of study, that I shall here prefer to speak.

And, in the first place, I must beg you to observe, that the mode of teaching medicine, so far as this can be done by lectures, is by laying down general doctrines and principles relating to entire classes of diseases and remedies, whilst particular facts are mentioned only as far as they serve to illustrate those principles, or as they are clearly deducible from them.

But, in commencing to study for yourselves, you must now observe the opposite and more natural mode of proceeding from particular facts, to establish or to confirm general principles. Now, I shall presently endeavour to show you in what way the mind should be disciplined, in order that it may lay up for itself a store of useful knowledge; how it should endeavour to drink in truth untainted by error; how, also, in the anxiety to avoid error, it should not fall into the opposite extreme of rejecting the truth.

It is true, that in the beginning you will have the aid of your teachers; that in every case which comes under your notice, you will do little else than play the part of observers; and that you will gradually be inducted into the arts of observing, of distinguishing, and prescribing.

You will reap also the greatest advantage from those bed-side observations and clinical instructions with which your visits at the hospital will be interspersed.

And if many hours daily spent in the anxious desire to make the means of clinical instruction there existing fully available to you, when but a portion of that time would suffice to do full justice to the patients—if care and anxiety to develope to the fullest extent the resources of the hospital, and to lose no opportunity of showing to you interesting cases and instructive operations,—if these and other efforts to promote your instruction, which you will experience in the course of your pupilage, at the hands of the Physicians and Surgeons of the hospital, can serve to excite you to industry and train you in good habits, then I am satisfied that you will experience them to the fullest extent.

But time will bring new opportunities and new employments; and thus in various ways, as clinical clerks, or as dressers, or in some other capacity, you will gradually exchange your former business for more active duties, and learn to feel that now, at least, some responsibility devolves upon you. And that you may neither waste nor misapply these opportunities, I shall here advert as briefly as possible to the circumstances which I think most likely to lead to that untoward result, reminding you at the same time, that, as my object is to warn you against errors rather than to recommend any special scheme of study, you must not here expect me to refer to matters which would be foreign to that intention.

If I were to ask any of you what is your object in attending the hospitals, you would probably answer, to gain experience. But if further I were to follow you to the bed-side, and observe the mode in which each of you set about the matter, I doubt not I should find you proceeding in different ways, and some, at least, in such a manner that the looked-for experience could never be attained.

"Let us," says Locke, "suppose the mind to be as white paper, void of all characters, without any ideas,—how comes it to be furnished? Whence comes it by that vast store which the busy and boundless fancy of man has painted on it, with an almost endless variety? Whence has it all the materials of reason and knowledge? To this I answer in one word—from *experience;* in that all our knowledge is founded; and from that it ultimately derives itself. Our observation employed either about external, sensible objects, or about the internal operations of our minds, perceived and reflected on by ourselves, is that which supplies our understanding with all the materials of thinking. These two are the fountains of knowledge, from whence all the ideas we have, or can naturally have, do spring."

Such, then, is experience; but practically experience is too apt to be regarded as the simple produce of the senses, whilst the understanding seems to come in for a much smaller share in the operation. Yet, unless both the powers which contribute to produce experience, are equally employed—that is, unless observation and reflection are made mutually to assist each other, the experience which results can be of no real value, or rather, it may be said to be no experience at all. False experience, then, is that which results from the use of observation without adequate reflection, or of reflection with insufficient observation, and both these kinds must be equally avoided.

Now, in endeavouring to acquire this experience

for yourselves, I hardly know which of these two errors you are the more likely to fall into; but whichever bias (if either) your mind should unfortunately take, you may be almost certain it will retain, and thus tinge with a false colouring all your subsequent acquirements. One or two illustrations of the consequences of this bias must here suffice.

A man who uses his observation only, and never reflects on what he sees, cannot be said to have experience, but only to acquire habits. He may, indeed, amass a certain quantity of information. He may make a large collection of cases, for example, and take great pains in recording all the symptoms which he observes; and these laborious and pains-taking compilers are sometimes useful to others who may have genius to turn their labours to good account; but to themselves these labours are almost entirely useless. Because, having no ideas of method or arrangement, or plans of any sort, or views of general principles, they can discern neither the resemblances nor the differences of things. For although facts afford the only solid foundation for true science, yet when disconnected they convey but little instruction.

Thus a man who observes, but does not reflect, contributes little or nothing of value to his profession. All that can be said of such an one is, that he does not advance the science of medicine. But the man who falls into the opposite extreme of reflecting without adequate observation, positively retards our progress, and that in many ways.

A sage being asked how he had derived his knowledge, replied, "From the blind, who never place their feet till they have tried the firmness of the soil: I observed before I reasoned, and I reasoned before I wrote." It would have been well for physic if this rule had always been observed; our time would not then have been spent, as much of it is now, in correcting the errors of our predecessors, and in endeavouring to unlearn what a previous age has advanced. Now these errors may, in the first place, be traced to the unwillingness which we in general feel to submit to the slow, but at the same time, sure method of proceeding in cases of philosophic inquiry by cautious induction. So slowly do our facts come in medicine, that we become impatient of the restraint, and endeavour, by a shorter road, to arrive at a knowledge of general principles, and to deduce general laws from insufficient or imperfect data.

Let me take one illustration. A clever physician, now deceased, announced to the Profession his discovery of the fact, that spasmodic croup depended upon pressure of the recurrent laryngeal nerve; and in proof of this assertion, he exhibited some specimens of morbid parts, in each of which the nerve was distinctly seen, imbedded in hardened masses of glands.

Now the facts were so evident, the explanation was so simple, and the inference seemed to follow so easily and naturally from the premises, and offered just that sort of explanation of the phenomena of the disease, which fell in most completely with what we know of the anatomy of the parts, and of the symptoms of the disease, that a large portion of the Profession hailed the announcement as an interesting and important discovery.

But it was subsequently found, that not only was the combination of enlarged glands with spasmodic croup not a constant, but that it was not even a common occurrence—at least, that a great many cases occur without this combination. Thus, without waiting for a larger number of examples which would either have confirmed or refuted the doctrine advanced, an attempt was made to establish a fact as general, which not only was not true of all the individual cases, but which did not belong to any, having no real connexion with the disease which it was made to explain.

So, also, the experience which we trust to from the testimony of others, is liable to the same imperfections with our own; and we are too apt to admit supposed facts in medicine, without a sufficient examination of the authority on which they are based. Men often mistake impressions for facts, and record that as the result of their observation, which is no other than the offspring of the imagination. Thus every part of natural history, and medicine above all others, is overwhelmed with facts which have no actual existence.

There is still another error of the same kind, but differing in some respects from the two that I have mentioned. This is the partial statement, or partial reception, of facts collected with a view to support particular doctrines. In no way do we see this mistake so constantly occurring, as in the attempt to make certain classes of disease appear to depend upon one particular condition, or to assign to certain classes of remedies, or even to individual medicines, an efficacy which does not really belong to them.

"There is a certain intoxication that usually attends the supposed discovery of general principles or useful inventions, which renders men of warm and lively imaginations altogether blind to every difficulty that lies in their way, and often makes them artfully suppress them. The suppression of facts that appear to contradict a favourite hypothesis, is not, however, always owing to want of candour in the author. Sometimes he does not see them, sometimes he despises them, and sometimes he conceals them from the fear of giving people an unreasonable prejudice against what he deems an important discovery."

Now, we cannot help regretting the self-deceit which thus prevents the mind from becoming the recipient of the entire truth; for not only has this failing a most injurious influence on the progress of medicine, but when concerned in the employment of remedies, it tends to diminish that confidence which a more cautious and candid mode of investigation could not fail to inspire. Every day, unfortunately, furnishes fresh examples of this wide-spread error. The first that we are ready to discover in others,—the last that we are willing to admit in ourselves.

"Oh wad some power the giftie gie us
To see oursels as ithers see us;
It wad frae mony a blunder free us."

But which of us may not with advantage apply this wish to his own case?

Let these examples suffice to point out the kind of errors into which you are likely to fall in your first handling or dealing with facts.

Your next endeavour must be, after having acquired an extensive collection of well authenticated facts, to arrange and classify these, according to their apparent relations, and to endeavour to deduce from them general facts, or general principles.

It is in this way, and with this view, that Nosologies are formed, which are the more valuable in proportion as they proceed upon the recognition of true analogies; but the less so as they depart from a natural and assume an artificial basis. Now, without some kind of general and systematic arrangement of our facts, it is obvious that we cannot make full use of the knowledge that we acquire, but it may be doubted whether, in medicine, nosologies can ever be of the same use that systematic arrangements are in other departments of physical science generally. Some, indeed, discard them altogether, as unprofitable or even hurtful.

Now, it is important that you should understand in what the value of these arrangements mainly consists, and in what respects they may be viewed as injurious to the progress of medicine. They may be said to do for you in books what lectures do for you during the early part of your pupillage. They serve to direct your mind to the objects of which you are in search, and to lead you to trace out among them, certain general principles and analogies; and in so far as they answer this purpose, and this only, they may be regarded as beneficial. But in so far as they may tempt you to overlook details, and to merge all facts in general principles, so that you get these by heart, and neglect the others, than they are positively hurtful.

But, without wishing to detract from the good that they may do, I must also point out another objection to which nosologies are not unfrequently open. One who sets about compiling a nosology amasses such a quantity of learning, that the mere frame-work necessary to contain it, becomes so cumbrous and overloaded, that it too often tends to hide the stores which it was constructed to reveal. Knowledge, in fact, is not only stored up, but is absolutely put away.

On the other hand, those who, in order to avoid this error, aim at simplicity of arrangement, are apt to pass into the opposite extreme, and to mar the value of the facts which they record, by bending them to the system; and, in this effort to reduce many diseases to a common standard, deprive them of their value as isolated facts. Diseases, in short, are here treated like the guests of that ancient Attic robber, on whose couch all travellers were alike compelled to repose. Fortunate was it for those whom the couch fitted; but woe to all whose stature failed to accord. The short were stretched, and the tall were shorn of redundant limbs, in order to procure uniformity in the result.

We are not, however, just now in danger of running on into either of these extremes; for the business of compilation seems, for a time at least, to be suspended; and our present occupations consist chiefly in the study of what are called "*specialities*." That is to say, the various departments of which the Profession has usually been deemed to consist, seem to be gradually subdividing themselves into smaller sections, each of which is investigating some special form of disease, or studying the pathology and treatment of some particular organ. This disposition to devote attention to particular studies appears to have imperceptibly crept over the Profession in our day. And so it is, that there are few of us who, when the name of a particular physician or surgeon is mentioned, do not almost involuntarily connect with it the notion of some disease or organ with which it has come to be associated.

Now, pathologists say, that this is just what is wanting to advance the progress of medicine—that the labour of observing should be a divided labour —and that, until we can thus work out the details which relate to the pathology and treatment of every organ and part of the body, we can make no real progress. Now, I think, we may well pause before we admit the correctness of this doctrine; indeed, I very much doubt whether the practice, now become so universal, will not rather in some respects retard us.

For we cannot separate the parts of the body as we do the objects of natural history, and regard them, either in their pathology or treatment, in an isolated form. "The eye cannot say unto the hand, I have no need of thee," any more than the brain or heart, for example, can be viewed as independent of the stomach.

This mapping out, therefore, of organs and parts of the body, and assigning their care to different hands, has practically this unfavourable result—that

it leads to the too exclusive consideration of the diseases of these particular structures, as things apart from the rest of the body, and not as essential portions of a whole. In some ways it is difficult to avoid this, because, as soon as the public learn that a physician or surgeon has made any special observations, or has published any particular views, they naturally wish to consult him with regard to diseases in which they may be personally interested. And as it very often happens that in these cases the public reverse the acknowledged rule, and regard "the prophet as without honour save in his own country," so a man's practice becomes, in time, chiefly limited to cases of a particular kind.

Let me give you an illustration of what I mean, by relating the following occurrence, which I believe is by no means a rare one:—A woman brought to me at the Hospital a strumous child, whom I immediately perceived to be suffering from ophthalmia. I was about to direct my attention to the eyes, when I was stopped by the mother, who informed me that it was not for that purpose she had consulted me, as "his eyes were under Mr. A—." Turning, therefore, my attention from the forbidden ground, I was about to examine the child's limbs, when I was again interrupted by the vigilant mother: "His limbs, Sir, are under Mr. P—." "Why, then," I inquired, "have you brought him to me?" "For his stomach, Sir, his stomach."

Now, we cannot help thus reflecting upon the results of a system which leads to the different organs being separated and carried about to different professors of our art; here an eye, there a limb, and there again an intestine, till we begin to think that it must have been something of this kind which Adrian meant when he caused it to be inscribed upon his tomb, that "it was the great number of physicians that killed the Emperor."

Now, I am far from wishing to undervalue, in the slightest degree, the labours of those who may have thus gained the highest reputation, or to suggest that that reputation is not most amply deserved; but I beg you to observe, that I am speaking not with reference to individuals, but with reference to the effect which the system or practice must ultimately have on the science of medicine. And this effect, in so far as it may lead to views of disease and views of practice, apart from the general consideration of morbid and countervailing actions, must, I think, in that degree be injurious.

Now, gentlemen, there are yet many other points regarding modes and objects of study, to which, had it been possible, I should have wished to direct your attention. There is, however, one consideration, relating not so much to the mode, as to the end or purpose of those studies, which, before I pass to a very brief notice of the remaining point that I have in view, I must not omit to offer you.

You are, doubtless, satisfied, that, in selecting Medicine, you have chosen an honourable and noble profession. The best and wisest men have ever so regarded it. But remember that with each of you rests the responsibility of upholding it in that light, in the eyes of those with whom you may be brought into contact. Men will properly interpret the view which you may entertain of it, through the medium of your own conduct; and that again will be regulated very much by the habits of thought and action which may have pervaded your early periods of life. Let me, then, while the mind is still plastic, and your habits are as yet mainly unformed, invite your consideration of those more exalted purposes at which medicine, whilst pursued and practised as a means of honourable subsistence, should still ever aim. These, together with the impediments which beset the path to knowledge, and are apt to lead the mind away from the ultimate purposes of its attainment, have been so ably pointed out by Bacon, that I cannot do better than present them to you in his own vigorous and striking language.

"But the greatest error of all the rest, is the mistaking or misplacing of the last, or furthest end, of knowledge; for men have entered into a desire of learning and knowledge; sometimes upon a natural curiosity and inquisitive appetite; sometimes to entertain their minds with variety and delight; sometimes for ornament and reputation; and sometimes to enable them to victory of wit and contradiction; and most times for lucre and profession; and seldom sincerely to give a true account of their gift of reason to the benefit and use of men; as if there were sought in knowledge a couch, whereupon to rest a searching and restless spirit; or a terrace for a wandering and variable mind to walk up and down with a fair prospect; or a tower of state, for a proud mind to raise itself upon; or a fort or commanding ground for strife and contention; or a shop for profit and sale; and not a rich storehouse *for the glory of the Creator, and the relief of man's estate.*"

The third and last impediment, which I must very briefly notice, originates in the mode in which the non-professional public view and receive medicine. Their ideas of the nature of disease, and of the action of remedies, are widely different from ours,—with which, indeed, they seem to have little or nothing in common. They imbody their notion of diseases in the form of entities, to which they give a "local habitation and a name." * And these they appear to refer to when, in describing their symptoms and sensations, they say, "*It* took me here, I feel *it* there." And their idea of remedy is that of a power, or substance, which is to have the effect of driving out these entities, and of leaving the body whole as it was before. But of morbid processes and countervailing actions they have not, in general, the smallest conception.

Further, they believe that each disease (so understood) has its own proper remedy, and he is the cleverest fellow in their estimation who has the surest specific for each disease, or by one *coup-de-main* can sweep away the whole.

Now, this I think may be said to be the foundation of the public mind in regard to its views of medicine, however they may vary in particular cases and individuals. And it is against such a notion in general that we have to contend.

Now, if persons who have not been educated to medicine would be satisfied with not thinking upon these matters, but would entrust themselves, as a certain portion only of the public do, with the same implicit confidence to the guidance of their medical advisers, that men do with another profession in regard to the management of their affairs, we should find one of the greatest impediments to the progress of medicine at once removed. But a large portion of the public desire to take an active part in the treatment of their own maladies, or at least to select for themselves the mode in which they will choose them to be treated. I need not observe how widely this opens the door to those numerous bye-ways which tend to corrupt the pure spring of medicine, and to those still more open quackeries that now everywhere abound. The love of the marvellous, the easy credulity given to bold assertions, and the "illusive flattery of hope," have ever, as they will doubtless continue to do, given encouragement to a thousand inventions.

It would be impossible to determine the extent to which the public encourage empiricism. We have the means of determining the exact amount of this only in one department—I mean that department in which the public decide, first on the name of their disease, and then treat it themselves with a medicine of which they do not know the composition.

The amount of taxes paid annually to the Government for patent medicines, exceeds 34,000*l.*, and as the tax bears usually a proportion of one-ninth of the value, and is invariably added, and therefore paid by the consumer, the sum thus represented would exceed 300,000*l.*, as paid yearly by the public for this class of medicine only, a sum far exceeding the united income of all the Hospitals and Medical Charities in this vast metropolis.

The time warns me, gentlemen, that I must close this very imperfect attempt to bring under your notice some of those more significant errors which, in our present day, and in the times more immediately preceding us, appear to have contributed most to obstruct the path of medicine.

The task of pointing out errors is always an unwelcome one, and he who attempts it, however he may feel impelled by a sense of the obligations of duty, sometimes lays himself open to a charge of motives which may be far from his intent.

I trust that nothing which I have said will, for one moment, convey to you the belief that I entertain aught but a feeling of the highest admiration and regard for the Profession which is our mutual choice, and for the members of which it is composed. But the praises of Medicine, or of its cultivators, was not my theme. Long may it be your high privilege to adorn the one, and to discern the excellencies and merit the esteem of the other.

But seeing by how many difficulties your present course is likely to be beset, and knowing the advantage which men may always derive from the experience of those who have trod that path before, I have thought I could best discharge the duty which the occasion has imposed, by showing you in what way you are most likely to be useful in your generation, whilst, at the same time, you should not be unmindful of those that are to follow.

Take for your object the improvement of your Profession in its highest and widest sense. View it in its several parts, but view it also as a whole. Let your separate labours be guided by the light of science; but whilst you cull from every fair and legitimate source, see that your gatherings may be so made as to be useful also to all posterity.

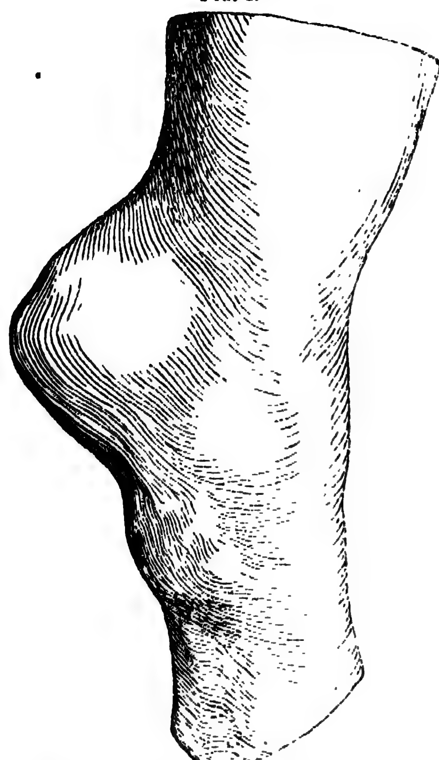
We have lately, as I have said, been made to feel but too painfully the feebleness of our art. There is in it still that dark centre which none of us have yet been permitted to penetrate; but it is surrounded by numerous sciences, which give it now a hopeful light. From that brilliant circle let it be your ambition each to snatch a burning brand, and, penetrating far with it the darkest recesses of the shade, there deposit your contribution of love. And let us hope, that in no distant day there may arise some mighty intellect, which shall gather up those scintillations, and combining them into one vast torch of truth, elevate it far above the obstructions of ignorance and folly, where it may burn with an unbroken lustre, and penetrate the remotest corner of the gloom.

CLINICAL LECTURE

ON A

CASE OF OSTEO-CARTILAGINOUS TUMOUR (OSTEOCHONDROPHYTE), REMOVED FROM THE FEMUR.

By R. QUAIN, F.R.S.,
Professor of Clinical Surgery in University College, and Surgeon to University College Hospital.



[Reported by EDMUND CARVER, M.R.C.S., lately House-Surgeon to the Hospital.]

After having made reference to some cases of exostosis which had, from time to time, been operated on in the Hospital, Mr. Quain continued as follows:—Although the case which is to form the principal subject of the present lecture has not been in the Hospital, still, inasmuch as it affords a good example of a disease seldom met with, and as I have in this cast of the limb taken before the operation, with the preparation and these drawings, ample means of illustrating all the most important facts, I am desirous to bring it fully under your notice. This is the history of the case:—

Miss B. E., a lady, aged 26, of nervous temperament, and delicate conformation, with fair skin and dark hair, has generally enjoyed pretty good, but by no means robust health. From the inner side of the femur of the right side, near its lower end, projects the tumour, of which she now complains. It was first noticed seventeen years ago, and from that time it has been increasing slowly in size till a few months since, at which time it began, and has since continued, to advance with greater rapidity. The mass itself has always been painless, but the integuments covering it are often injured by knocks against chairs and other articles of furniture, while Miss E. is engaged in her household occupations. It has thus become a source of great inconvenience, as well as of considerable anxiety of mind to the patient, so much so, that her medical attendant (my friend, Mr. Boxall, of Sussex) was led by careful observation to conclude that her health was suffering from this very anxiety.

The tumour (this part of the report, it may be observed, you will find verified by the cast of the limb in the neighbourhood of the knee-joint, which I now place before you) is about the size of a clenched hand of ordinary size, and is pyramidal in shape. Its long diameter is in the direction of the limb, but with a degree of obliquity, the lower end being inclined into the popliteal space under the

FIG. I.

This figure has been taken from the cast on a reduced scale. The position of the morbid growth with reference to the patella is marked.

muscles which bound the space on the inner side, while the upper end is directed forwards upon the anterior aspect of the bone. When the knee is straight, the tumour is close to the patella (see the cast); in fact, its lower end, in this position of the joint, is somewhat lower than the level of the top of that bone. In consequence of this circumstance, the garter has been worn close to the upper end of the patella, and, in order to fix it there, has habitually been tied very tightly. On the other hand, when the knee is flexed, the patella descends so much that the tumour then appears to be free of the joint.

The swelling is immovably connected with the femur; it is hard—bony to the feel; is uneven on the surface—a series of blunt, pointed processes projecting all over it.

The femur has its natural shape; and it does not, in any degree, blend with the diseased mass.

The surrounding soft parts are healthy; so, likewise, are the lymphatic glands in the groin. There is, in short, no evidence of any constitutional taint, either in the condition of the structures in the neighbourhood of the disease, or in the aspect of the patient. Nor does the appearance of the patient give any indication of impaired constitution.

The facts detailed in the foregoing narrative appeared to me to lead to the following conclusions respecting the nature of the disease, viz:—

1st. That, considering the slowness of the growth of the tumour, as well as its hardness and the absence of pain or uneasiness in the part, together with the sound state of the surrounding structures, and the freedom from all appearance of constitutional taint in the patient, the disease was not "malignant." If the circumstances had been the opposite to those now enumerated,—that is to say, if the morbid mass had been rapid in growth, and soft or yielding to pressure,—if it had been painful, and if the neighbouring soft parts had been involved in the disease, there would then be evidence of "malignant" disease, (soft cancer, probably). The only possible remedy, in these circumstances, would have been the removal of the limb at some distance above the disease; and, even after having resorted to this extreme measure, the Surgeon has, in such a case, too much reason to apprehend a return of the disease elsewhere, and at no distant time.

2ndly. From the fact of the femur being unaltered in shape,—not swollen or expanded into or upon the tumour, which rather rose abruptly from its surface,—this inference seemed legitimately to flow, namely, that the disease arose from the external surface of the osseous structure; in other words, that it did not pass outwards from the interior of the bone. The importance of this conclusion will be manifest, when it is considered that, had even a non-malignant growth of the kind, from time to time, developed in bones, (for example, a cystic one, or an enchondroma, or some form of osteo-sarcoma,) been formed within the substance of the femur, it would have been a question for serious consideration, whether the disease could, with safety, supposing the measure practicable, have been scooped out from the interior of a bone so large, and surrounded with a great thickness of soft parts, notwithstanding the favourable result which would be likely to attend the operation for similar disease in a small bone, or one less thickly covered. Amputation would, in this case, too, most probably have been necessary.

Lastly. Having determined the diseased structure to be a non-malignant one, and that it was only appended to the surface of the bone, it was, in the next place, inferred, from its hardness, that it consisted of bone, or of a mixture of osseous and cartilaginous tissues,—in short, that it was an exostosis, or an enchondroma containing osseous matter. Which of those textures the tumour was most likely to prove could not have been determined with certainty before its removal. Nor was the decision of any importance in a practical point of view, for in either case the disease was to be remedied only by entire removal; and both those structures are equally suitable for the operation. But, it should be added, exostoses, after growing to a certain size, in some instances, then remain stationary; and, if they produce no actual distress, it may be well to avoid the risks of an operation. In the present instance, however, the mass had been lately increasing somewhat actively, and it lay very close to the capsule of the knee-joint. Any considerable augmentation of size would augment the risks of the operation, for the parts interested in it would be more extensive, and the integuments would probably become ulcerated from pressure, so as to produce an open sore, with all its attendant evils. Moreover, the capsule of the knee-joint might become involved; and, in this event, the removal of the disease would probably be inadmissible, except with the limb itself. To these facts must be added, as no unimportant consideration, the anxiety the patient felt to be relieved of the disease, as well as the influence of this anxiety upon her health. Such were the grounds upon which the speedy removal of the tumour was recommended. Sir B. Brodie, I may add, who saw the case in consultation, agreed in the opinion that the operation ought to be performed.

The Operation.—A tourniquet having been applied, and the limb moderately bent at the knee, a longitudinal incision was made over the whole length of the tumour at its back part, near to, and in front of, the long saphenous vein; and from this another incision was drawn across the middle of the tumour to the anterior border of its base. With the integuments and the vastus internus, which formed two large angular flaps, was raised a layer of fat lying beneath the muscle, the edge of the knife being kept as strictly as possible to the very unequal surface of the tumour during the dissection.

The soft parts having been turned aside, the morbid growth was felt to be unconnected with the femur at the circumference of its base, but the interval between it and the bone was very narrow; so much so, that only a narrow chisel could be inserted. The short pedicle, if such it could be called, was now cut through with the chisel, and the investing membrane having been divided, the tumour was easily removed.

During the operation, the patient was under the influence of chloroform, administered by Dr. Snow; and Messrs. Boxall, Ellis, Cadge, and Clover, kindly lent me their assistance.

Progress of the Case.—From the 15th of December, the day on which the operation was performed, to the 20th, there was no swelling, except about the wound, from which serum oozed in good quantity. On the 21st, the prominences of the knee were indistinct, in consequence of swelling about the joint; and subsequently fluctuation was felt, owing, apparently, to a little effusion into the synovial sac; but this effusion and fluctuation were perceptible at the outer side of the patella, while none existed between the patella and the seat of the operation.

On the two following days, (22nd and 23rd,) now a week from the operation, small patches of yellowish red colour appeared on the outer side of the knee, and afterwards discolouration of the same kind, became pretty extensively diffused over the upper part of the thigh,—all at the outer side. The same appearance likewise showed itself, at a later period, on the inner aspect and fore part of the leg. A slight streak of redness was also found on the abdomen near the groin, and the inguinal glands became painful. The redness was attended with slight elevation of the surface, and tenderness to the touch. After the lapse of three days, the patches of discolouration began successively to fade, and the skin, at the same time, ceased to be tender to the touch.

A couple of days after these appearances had presented themselves on the limb that had been the seat of the operation, a rose-coloured patch was manifest on the nose, which then became swelled, and the cuticle was elevated into a vesicle. The redness and swelling soon extended to the forehead and eyelids. As at other points before referred to, the discolouration, after remaining a single day at its height, disappeared, its whole duration, at any one point, being about three days; but a small abscess formed below the left lower lid, which had been more swollen than the upper one.

January 3rd.—There has been no further appearance of the erythema, and there remains only the vestiges of the patches before adverted to, marked by slight scaling of the epithelium.

This evidently erysipelatous eruption was attended with but little constitutional disturbance. The pulse, indeed, was accelerated,—it ranged from 108 to 120; but the heat of the skin was not at any time extreme. Indeed, on the upper part of the body, the skin was generally soft and moist, and at night it was bedewed with perspiration. The tongue was always moist, and for only a short time slightly furred at the middle. There was no wandering of the intellect at any period, and the appetite for food was not much impaired.

As regards medical treatment:—It consisted chiefly in the administration of small doses of muriate of morphia (subsequently of tincture of opium), and mild aperients, colocynth pills with simple enemata.

On the subsidence of the slight fever, the patient seemed doing, in all respects, well; but, in a few days, and after all the erythema had vanished, some uneasiness was complained of about the right hip. The patient now said she had often, at former periods, felt discomfort in this situation, and that there had always been some enlargement of the part. Examination being made, the sensibility was found to be seated about the great trochanter of the femur. At first there was exquisite tenderness to the touch, and a slight fulness; and in some days fluctuation became distinctly manifest. The fluid was not circumscribed by any distinct boundary. In order to evacuate it, an incision was made on the outer side of the thigh, and another behind the trochanter. The purulent collection was seated beneath the fascia lata. Matter likewise formed, a little afterwards, at both sides of the leg, and was

evacuated through openings made for the purpose. The discharge of pus was not continued for more than a short space of time at any point. Once fully evacuated, through openings suitably placed its formation ceased, and the wound closed. But another circumstance occurred to delay, in a degree, the progress to entire recovery. In consequence of the patient having been confined, by reason of the condition of the limb, in a great measure, to one position,—on the back,—a superficial bed-sore made its appearance in the usual situation, over the sacrum. This rendered a water-bed necessary.

While the patient suffered from the formation of purulent matter and its consequences, the constitutional disturbance was at no time considerable. The pulse, indeed, was rapid, ranging from 120 to 130 and even 140; but the expression of the countenance was always good, the eye clear and intelligent, the skin soft, the tongue usually moist and pretty clean. Food was taken, the while, in good quantity, and with decided relish.

In the medical treatment, when pus was being freely discharged, there was added to the use of opiates and an occasional aperient, quinine with sulphuric acid; but for the quinine, as it seemed to disagree with the stomach, infusion of cinchona was speedily substituted, apparently much to the advantage of the patient.

Finally, notwithstanding the interruptions adverted to, recovery went steadily on. The wound made in the operation healed up, even while the abscesses were forming; and before she left her bed the patient had gained flesh considerably. Her face was decidedly fuller, and her countenance was altogether indicative of sounder health than when she came to town before the operation. She herself declared, that she felt now more in health than she had done for some years before. After her return to the country, I learned from Mr. Boxall, that our patient continued to be remarkably well, and that she was regaining the use of the limb, in which there was some stiffness when she left London.

Observations.—Taking now some of the most important of the circumstances for remark, and in an order different from that in which they have been narrated:—Here is a mild attack of traumatic erysipelas, (the "surgeon's plague," as it might be called,) not occurring in immediate connexion with the wound of the operation, but commencing at a little distance from this, showing itself then successively at different and distant parts,—the face, the abdomen, the outer side of the limb, (the operation having been on the inner side,)—and running its course rapidly, in about three days at each point. And so it would have passed off without causing impediment or delay to the patient's convalescence, had it not been for the formation of abscesses. To these I would now direct your attention.

After an operation, or a wound of any kind, the formation of pus in any amount is always a serious complication. The position in which it is deposited is, however, a material consideration in forming an estimate of its probable effects on the result of the case. Where, for example, (and I will now only state results, without entering upon any detail of the facts from which they are deduced,) where abundant purulent secretion occurs in connexion with the seat of the operation, and burrows along the periosteum, which, in such cases, it has a tendency to, the effect is very unpropitious; and where the deposit forms at a distance from the place of operation, and not in connexion with the erysipelatous inflammation of the surface, but occurs in the joints or in the viscera, (in the lungs, for instance,) the consequences are disastrous. In the case we are engaged in reviewing, the abscesses had no communication with the wound, and they were the immediate result of the local erysipelatous inflammation. Under these circumstances, apart from the condition of the patient's system, the depth and extent of the purulent deposit are chiefly to be taken into account. It is material, then, to observe, that the abscess was near the surface, and did not involve the muscles; moreover, that the purulent secretion ceased almost altogether with the evacuation of the contents of the abscess.

Again, as to the general state of the patient: the health was not, at any period, in an unfavourable condition; the pulse, indeed, was very rapid, but the rapidity of the circulation *per se* (that is to say, other circumstances being favourable, or even not unfavourable) is not to be regarded as an indication of any serious import. In conducting the case to its favourable issue, the most decided advantage was derived from the use of opiates. With a person of highly nervous temperament, as this patient might be said to be, it is most important to remove pain; and it is in procuring this effect, in other terms, it is as an anodyne rather than as a soporific, that opium, in some form, often affords so much assistance to the surgeon.

Nature of the Tumour.—The tumour is, as you observe, very irregular on the surface. Compact at the middle of its base, it is divided all over a large part of its circumference into a series of processes, which stand out from the base, and support, like so many pedicles, the thickened and rounded extremities. It has, in fact, a cauliflower arrangement, the enlarged extremities being, however, rounded off, as before stated. After a section has been made,

FIG II.

This figure represents the surface of a longitudinal section of the tumour, the longest and least curved margin being the base. The structure of the mass is indicated, the three substances of which it is composed being distinguished in the following manner:—Over the proper bony structure are seen small cells, the section of canals. The white parts (those not marked with the artist's graver) represent the dense white substance of the mass; while the cartilaginous parts are denoted by uniform and uninterrupted lines.

the mass (as you will see on inspection of the preparation) consists chiefly of bone, but with some soft cartilage at certain points. The latter structure occurs in small separate pieces towards the circumference of the tumour; and a thin layer of it covers over the surface. The osseous portion resembles very closely ordinary bone; but no inconsiderable portion of the mass near its circumference consists of white dense substance, looking as if calcified. It is within this imperfect bony structure that the cartilage is met with in insulated patches. The whole has fatty matter mixed with it in considerable quantity.

The mass was sessile upon the femur. It sprang from an elongated and narrow part of the bone, (see engraving,) the outer dense covering of which was continued into the surface of the tumour, so that when the diseased growth was removed the cancel-

FIG. III.

The base of the tumour is here represented. The place at which it was connected with the femur, and the proportion this bore to the extent of the base are at once distinguishable.

lated structure of the bone was bare. From a consideration of the small size of the connexion between the two, it would appear as if a certain extent of diseased surface of the femur gave origin to the tumour; but that, while the latter became enlarged in every direction, the bone itself was no further affected by the diseased action.

An example of a tumour growing from the humerus described and represented in M. Cruveilhier's work on Morbid Anatomy, ("Anat. Pathol. du Corps Humain," liv. xxxiv.), seems to be in all respects of similar composition to that now before us. The mass was, however, in that instance, of very large size, and was extensively connected with the bone from which it grew. It had been removed by M. Roux, by amputation at the shoulder-joint. For such growths M. Cruveilhier has proposed the distinctive name "osteochondrophyte."

Remarks on the Operation.—I have already said, that if purulent secretion occurs in any abundance at the place of operation in such a case as that we have been engaged with, the pus is likely to burrow along the periosteum, or amid the muscles. In order to guard against this evil, as far as the mode of operating can tend to this object, it is best to divide the muscles freely, and in such manner, that the matter, when formed, shall readily find its way outwards. With this view, in the case under observation, the vastus internus was cut completely across. For the same reason, it is prudent not to close up the wound in dressing it. To do so is useless, for immediate adhesion will not take place, and it may be injurious, as the pus necessarily formed may, in consequence of the arrangement of the dressings, be prevented from an easy escape.

The important parts in the neighbourhood of the tumour which it was indispensable to leave uninjured, were the popliteal vessels and the synovial membrane of the knee. Now, in all operations for the removal of diseased growths, the parts contiguous are best avoided by keeping the edge of the scalpel, during the dissection, sedulously to the surface of the mass to be removed, and this was all that could here have been required, in so far as the blood-vessels were concerned. But the synovial membrane is very thin and loose, and covered with fat, while, at the same time, the tumour was so uneven on the surface, that to follow the rule just mentioned completely out in the dissection, was not possible. For reasons, therefore, which these circumstances will at once suggest, it was important, in the present case, to lay down, as nearly as possible, the exact limits of the synovial membrane. To this end, I examined the parts on the dead body before the operation. This drawing is an exact representation of a dissection made after the synovial membrane had been nearly filled with injection;—we are at present concerned, it is to be borne in mind, with the membrane in so far only as the anterior and lateral surfaces of the femur at its lower end are interested. The following are the facts most important for the purpose in hand, which appeared in the dissection:—

1. The healthy synovial sac extends upwards two and a-half inches above the top of the patella. But this bone is moved, and with it the sac, as the joint is moved, insomuch that, when this last is forcibly bent, the patella and the upper end of the sac are two inches lower than they are in the extended position of the limb.

2. The sac gradually narrows upwards from the articular surfaces of the femur, the breadth at the lower end measuring about three and a-half inches, (or the breadth of the articular end of the bone,) and at its upper end about one inch. It is entirely in front of the bone, *i. e.*, does not cover any part of the side of the condyle.

3. To the femur, the sac is adherent only along the edge of the articular surface. Elsewhere it is merely in apposition with the surface of the bone, or is separated from it by a thin layer of loose fat. In front of the joint, on the other hand, the sac is intimately adherent to the muscles for some space (about an inch and a-half); and to the fore part of its upper surface, two narrow fleshy slips, known as the subcrureus, are connected, rather loosely, however.

From the foregoing anatomical facts the following practical inferences are deducible:—During an operation for removal of a tumour from the lower part of the femur, the joint ought to be flexed. The greatest danger of wounding the synovial membrane occurs when the tumour to be removed is situated towards the front of the bone. But even when the disease to be extirpated is in this position, it seems possible to turn down the synovial membrane with the anterior muscles from the femur, and likewise from an exostosis in this situation, provided always, however, that no unnatural adhesion has taken place. It is manifest that in any attempt to acccomplish this object, the incision through the muscles to reach the bone must be made sufficiently wide of the sac at its upper end.

The observations I have thought it necessary to make on the nature of the disease from which Miss B. E. suffered, as well as on the operation and the general management of the case, are concluded. I wish now, however, before parting with the subject altogether, to allude to a curious fact, which has not hitherto been adverted to, because it seemed to have no direct bearing on the management of the case, though it is still of too much interest to be passed over wholly without notice. By the statement of the patient, which is noted in the narrative I read to you, to the effect, namely, that her right hip was always somewhat larger than the left, I was led to institute a careful examination, and this resulted in affording proof, not only that the statement alluded to was correct, but that the whole of the right side, so far, at least, as it could conveniently be examined, was a degree larger than the left. The circumference of the arm, of the forearm, the thigh, and the leg, measured on both sides, showed a difference varying from half an inch to an inch and a half. Moreover, on close inspection, a difference of the same kind was found to exist between the two sides of the face, and the prominence of the os frontis was slightly larger on the right than the left side. As the greater size of the right side was obviously owing to the bones, the co-existence of the excess of bony deposit in the skeleton with the diseased formation on the same side of the body, must be regarded as an interesting fact.

Because of their bearing upon the same subject, I will here briefly mention two other examples of hypertrophy of portions of the osseous system, which have come under my observation.

1. A young man of unhealthy, scrofulous appearance, sent into the hospital by Mr. Hillman, to be treated for some ulcers, was observed to walk with a particularly awkward gait. Upon investigating the circumstances, I found the tibia of one side to be considerably (nearly two inches) longer than its fellow; and I ascertained, at the same time, that it exceeded by so much its due proportion to the other division of the limb. The bone was arched forwards at its middle, and the skin over it was ulcerated to the extent of from two to three inches. The difference in length between the limbs was first observed a few years previously.

2. A boy, aged 16, admitted into the Hospital under my care, was found to have a large aneurism by anastomosis, extending over the under surface of the right foot as far as the heads of the metatarsal bones, and upwards as high as the internal malleolus. Being led to make a minute examination of the case, I ascertained, by careful measurement, the circumference of the leg and foot on the side affected with the disease of the vessels to be considerably greater than on the opposite—the sound side. It turned out, too, that the limb was an inch and a half longer than its fellow, the measurements being taken between the anterior superior spines of the iliac bones and the lower edges of the internal malleoli respectively; and this excess of length was shown to belong exclusively to the bones of the leg. The whole right foot, it should be added, was considerably enlarged. In this case the pulsation of the femoral popliteal and tibial arteries was much stronger, and the vessels seemed proportionably larger on the diseased side.

In the example of hypertrophy of certain bones last adverted to, the bones, doubtless, partook with the muscles in the augmented nutrition consequent upon the increased circulation in the limb; and to this is to be ascribed the augmentation of their size. But the same reasoning does not apply to the cases previously mentioned; inasmuch as evidence of augmentation of any portion of the vascular system did not exist. The slight healthy enlargement of a portion of the osseous system, and its co-existence with a diseased osseous growth in one of the cases, as well as the morbid enlargement of a portion of the bones of one limb in the other, must, I apprehend, still remain without reasonable explanation.

LECTURES

ON

OPERATIVE OPHTHALMIC SURGERY.

DELIVERED AT THE CENTRAL LONDON OPHTHALMIC HOSPITAL.

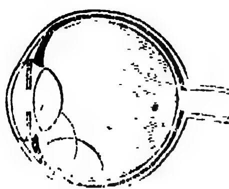
By H. HAYNES WALTON, Esq., F.R.C.S.,
Surgeon to the Hospital, and to the St. Pancras Royal General Dispensary.

LECTURE VI.

Displacement.—Nature of the Operation.—Circumstances rendering it preferable to Extraction.—Three modes of operating.—Results.

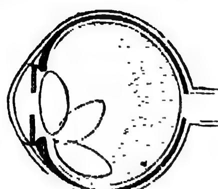
Displacement.—GENTLEMEN,—By the operation for displacement, the cataract is not taken away, as in extraction, but is pushed out of the field of vision and impacted in the vitreous humour; it therefore becomes, in all respects, a foreign body in the interior of the eye. Displacement, as I have said elsewhere, is applicable to hard cataract only, but it is very rarely resorted to, unless there is some especial cause why the operation for extraction should not be performed.

A very small anterior chamber, and adhesion of the iris to the cornea, or to the capsule of the lens, have been spoken of, at the end of the fourth lecture, as objections to extraction. Other adverse reasons to it are, chronic cough, difficulty of exposing the globe sufficiently for the effectual division of the cornea, on account of its being deep-seated, or the brow being very prominent, or the palpebral fissure unusually narrow; and, lastly, unhealthiness of the vitreous humour.



Whether any given case shall be considered unfitted for extraction, and better adapted for displacement, on account of mechanical difficulty, must often depend on what the operator's proficiency and skill may be. I have seen the cornea divided in the most perfect manner, and the iris uninjured, when the narrow dimension of the anterior chamber seemed to render such an effect almost impossible. Great practice and dexterity were brought to bear. Then, with regard to the cases of contracted lids or deeply set eyeballs, some men would reject what others undertake—and do well.

Judging from my own experience, I should say, that with those accustomed to eye operations, the latter causes very rarely deter them from extraction, although such cases demand peculiar nicety. Whenever I have to encounter such difficulties, I use a small knife, that ordinarily employed is unnecessarily large for any eye, and decidedly objectionable when there is impediment arising from want of room.



Unhealthiness of the globe renders displacement as inapplicable as extraction, and perhaps more so, except it consist in unnatural fluidity of the vitreous humour; and, even then, if the cataract could be removed, without the risk of a large portion of that humour being lost, the superiority of extraction would be great.

There are three ways of producing displacement. The oldest and now almost exploded method, "depression," is to pass the cataract downwards, till it

disappears. This diagram displays the position th lens is supposed to take.

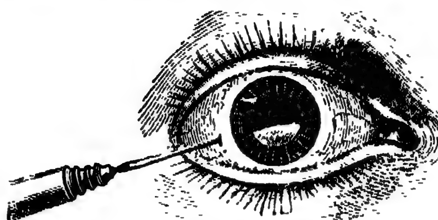
The next mode, "reclination," disposes of the cataract by tilting it backwards, and then turning the upper edge downwards, as is illustrated in this second figure.

The more important parts within the eye, are very much less likely to be pressed on or injured by a reclined than a depressed cataract, although vitreous humour suffers more lesion by reclination, especially if it be healthy.

Diagrams of operations are likely to deceive and mislead, by the precision and accuracy which they display. This is very applicable here. The cataracts are presented as passing through their several portions, and ultimately resting just at the desired spots. Now, in reality, there is the greatest uncertainty as to where they may go, especially in depression.

In reclination, all that we can be sure of is, the turning of the cataract back; but the position it afterwards occupies is a mere matter of chance.

I shall describe displacement by reclination, omitting altogether any notice of depression. Only one instrument is required,—a needle of some sort. That here represented is the kind in most general use, and is the best adapted for the purpose.



The pupil should be fully dilated. An anterior operation, through the cornea, has been proposed, and adopted by some, but is most inappropriate for the end to be fulfilled. It is only by passing the instrument through the sclerotica, that sufficient command can be tained for proper displacement.

The position of the patient, that of the operator, the manner of securing the lids and fixing the eye, should be precisely the same as if extraction were to be done. The needle, held with the convexity upwards, the handle a little depressed, to render the entrance of the curve more easy, should be introduced exactly in the transverse axis of the globe, about the sixteenth of an inch behind the cornea, avoiding the ciliary processes, retina, and long ciliary arteries, and directed inwards to the centre of the vitreous humour, then the point being carried forward, should appear between the upper part of the cataract and the iris, the needle turned, and its concavity applied on the cataract just above the centre. It must first be tilted, and afterwards pressed backwards and downwards, and made to assume, as near as possible, the position represented in the diagram. The needle must be kept on it for a few seconds, and then liberated by a slight rotatory motion, raised to the centre of the eye and withdrawn. Each step of the proceeding should be effected very slowly.

Should the cataract rise as soon as the needle is disengaged, the reclination must be repeated till it remain displaced. If, after several trials, it still re-ascend, the needle must be passed upwards and downwards between its posterior part and the vitreous humour, and laceration of the humour effected before a last trial.

Some operators think it necessary to lacerate the posterior part of the capsule before commencing the reclination. The re-ascension of the cataract is owing to the resistance offered by the vitreous humour, which must be in a healthy state, to possess that elasticity. The advantage arising from the application of the needle, between the lens and the vitreous humour is not derived, as stated by Dr. M'Kenzie, by separating adhesions between the capsule and the hyaloid membrane, but by the hole, or breach that is made in the vitreous humour. Probably, the correct practice would be, to proceed to make a rupture in that body, for the reception of the cataract, as soon as it is perceived that its elasticity offers an impediment to displacement.

This diagram may, perhaps, render more intelligible the description I have given of reclination:

If the anterior part of the capsule have not been sufficiently torn in the first instance to allow of a clear pupil, the needle must be applied to it, before being withdrawn.

Should the cataract be accidentally projected into the anterior chamber, it must be extracted. The iris being now partly, or entirely behind, can be avoided with the knife. It is recommended to make a small section in the cornea when a dislocated lens is to be removed, and to draw it out with a hook. Never having had to deal with such a difficulty, I can only tell you what others say. Sometimes a needle is passed through the cataract to steady it, and keep it *in situ*; while the cornea is being cut, I imagine the cataract-knife must pass through the cataract and the cornea at the same time; with such manœuvering destruction of the eye must be expected.

The cataract may fall into bits under the pressure of the needle. It would be impossible to effect the depression of pieces, and all that you can do is to leave them alone, except they produce irritation in the chambers of the eye, when you must extract them.

I have never seen displacement attempted when there has been adhesion of the pupil to the capsule of the lens. One or two adhesions cannot have much influence on the operation; and need not, indeed had better not, be broken across with the needle, as has been advised.

Entire papillary adhesion renders displacement as inapplicable as extinction; for, independently of the pupil being so small that it would be impossible to see what you were about, the iris must be considerably damaged before the needle could be made to appear in the front of the cataract; and if the capsule be opaque and thickened, as in all probability it would be, it will offer resistance to the needle and not yield to its pressure, and the iris is more likely to give way from its ciliary connexions than at the remaining adherent points. In such cases, "drilling" is the proper operation.

The third plan of displacement originated with Mr. Egerton, of Calcutta. The needle should be pear-pointed, and introduced into the eye just in the manner I have described for the last operation; but, instead of the point being carried to the centre of the vitreous humour for the purpose of avoiding the cataract, it is purposely passed through the cataract, the lower part of which is turned backwards, and in that oblique position is carried downwards. The late Mr. Scott used to displace by this method; but he thought it preferable not to transfix the cataract. His directions are, that "the needle should be inserted at the margin of the lens as far as it can be introduced into that body without displacing it inwards."

The supposed advantages of Egerton's plan are less injury to the hyaloid membrane, and the greater facility with which the cataract can be placed in any given position. It is better to lacerate the anterior part of the capsule, by an after-operation through the cornea, than to do it before the needle is withdrawn from the eye, because the return of the cataract to its place would thereby be endangered.

The direction to pass the needle as far as it can go without displacing the cataract inwards is very indefinite. Some cataracts are displaced by a very slight touch, and others would not move while the needle passes entirely through them. If the needle can be introduced into two-thirds of the cataract, sufficient command of it will be obtained. When it cannot be so pierced, the operation is not applicable. It is to effect the easier disengagement of the needle that Scott introduced his modification.

While at Moorfields I saw Scott operate several times, and my impression is that Egerton's is the best way to displace. I have never done it myself; why, I should be puzzled to say. In the few instances that I have resorted to displacement, reclination has been my operation.

You will not require to be told why a soft cataract cannot be pushed aside with a needle. I have seen an attempt made at it.

It is a great objection to displacement, that for its execution the interior of a healthy eye requires to be so much damaged. No condition of the vitreous humour can be said to be favourable for the operation. When, from morbid change, it readily yields to pressure, there is danger from the cataract, by its gravity, sinking and resting on the retina; or it may float about in it, and produce constant annoyance, by temporarily interrupting vision.

It is not surprising that acute inflammation of some, or all of the textures of the globe, with its consequences, should sometimes immediately follow displacement. But what is most to be dreaded is a slow, yet certainly destructive inflammation coming on at a future period, beng induced from pressure of the cataract on the iris, ciliary processes on retina, or violence done to the structure of the vitreous humour, or irritation occasioned by the unnatural position of the cataract. So long as the cataract is undissolved, and many years may pass without scarcely any change being effected in it, there is danger of this slow inflammation. Besides, the cataract may re-ascend in the tract by which it was displaced, or pass into the anterior chamber, and require to be again thrust back or extracted. Considering all these contingencies, permanency of success can never be reckoned on.

HOSPITAL REPORTS.

KING'S COLLEGE HOSPITAL.

On Saturday last, Mr. Fergusson performed the operation of Chopart. The case was that of disease of the anterior part of the foot, which had existed only for three months. It had at first been considered to involve the soft parts alone; but during the last few weeks, the disease rapidly increased. Successive abscesses formed, which were found to lead down to diseased bone, and the health of the patient was much pulled down. Mr. Fergusson therefore considered it proper to remove the disease.

The operation was performed in the ordinary manner, by carrying a large bistoury across the tarsus, entering the joint, and then making a long flap from behind. The operation is in this manner completed by most surgeons; but we observed, that Mr. Fergusson sawed off the projecting heads of the astragalus and os calcis.

On cutting into the amputated portion of foot, it was found that there was extensive disease of the soft parts, and complete destruction of the joint between the first metatarsal bone and the inner cuniform.

There was no other operation. But, the girl upon whom Mr. Fergusson performed the operation of excision of the head of the femur at the be-

ginning of the year, was shown to the students, as she had been brought up from the country, furnished with a high-heeled boot.

There was a firm healthy cicatrix in the site of the original wound; the limb was perfectly straight, and as well developed as the other in its circumference, but it was about two inches shorter, which circumstance, however, was remedied by the high-heeled boot, upon which she can walk without the help of stick or crutch. The motions of the new joint formed were very free. The little girl appeared to be quite robust, and in good spirits.

Mr. Fergusson stated to the students, that he was extremely delighted at having the present opportunity of showing to the pupils the result of the operation of the excision of the head of the femur. They could see, for themselves, the condition the patient was now in, and those who had known the child before the operation was put in force, would hardly recognize her as the same person. The limb was about two inches shorter than the other, he having removed between three and four inches of the thigh-bone, but the motions of the new joint were perfectly free.

They were aware that there had been much discussion respecting this operation, some having doubted its propriety, and denied that it could be of any use. For his part, he had now been more than twenty years in the Profession, and had seen a great number of cases of diseased bone cured by operation, and the case under notice afforded them one of the most striking examples of cure by operative interference.

PROGRESS OF MEDICAL SCIENCE.

FRANCE.

[From our own Correspondent.]

THE CHOLERA.

We have at length arrived at the very last period of the epidemic; indeed, it may be said to have ceased in the city, where not a single death from cholera has occured during the last two days. It still lingers, however, in the hospitals, and with the same remarkable peculiarity which I observed in a former letter,—*viz.*, a mortality of more than 50 per cent. on the cases admitted. The malignity of the epidemic thus remains unabated to the end. This is a curious and, I believe, novel point in its history; for we were hitherto accustomed to think that the decline as well as the commencement of the disease was marked by a certain degree of tractability, which distinguished them from the middle or violent period. In Paris, such has not been the case. The average number of admissions into the different hospitals for the past week has been eleven; the average of deaths, six to seven a day.

Another point worthy of notice is the persistence of the disease in hospitals, and other large public establishments, after its cessation in the town. This would lead to the idea either of *foci* of infection from agglomeration, or to actual contagion from proximity.

Thus, of the 22 cases reported from the different hospitals for the 5th and 6th of October, 16 occurred in the hospitals, and only 6 admitted from the city. The total number of cases remaining is 192; of which 61 are at the Hotel Dieu, 35 at le Pitié, 24 at St. Louis, 18 at Beaujon, and 7 at la Charité. The great majority, moreover, of these patients do not remain in hospital as convalescents from cholera, but from the various diseases under which they laboured when the epidemic seized them in its grasp.

The accounts from the provinces are still very discouraging. In the south of France indescribable confusion and terror prevail. The inhabitants of the large cities attacked take the extreme, but, at the same time, prudent measure of abandoning their habitations altogether. Thus, Toulon is represented as almost completely depopulated; not more than 10,000 persons remain in the town. This cholerophobia has given rise to an incident which excited great sensation in the military world, and which, for the honour of the Medical Profession, we trust may be unique. The chief Surgeon of the military hospital fled with the rest of the inhabitants alleging as an excuse that he had just succeeded to a fortune of 100,000 francs, and saw no longer any necessity for risking a life which had now become precious to him. His selfish and dastardly conduct soon met its reward. The *Moniteur* contains an "order of the day," signed by the Minister of War, and countersigned by Louis Napoleon himself, in which the unfortunate man is stigmatised as "a coward and as a deserter," dismissed ignominiously for having abandoned his post in the hour of danger, and condemned to three months' imprisonment for pusilanimity.

At Lyons, again, a curious scene is said to have occurred at the theatre, during the performance of "*La Jeunesse des Mousquetaines.*" A gentleman in the pit, having mounted on one of the benches demanded a moment's attention. Dead silence immediately prevailed, whereon the speaker asked if Mr. B. were in the theatre. The person thus addressed came forward in the boxes, and was informed, in the same tone, that his mother, whom he had left in health, was expiring from cholera, and entreated her son to return without delay. This announcement of "the king of terrors," the midst of enjoyment, produced an indescribable effect, and the theatre was soon empty.

A case similar to one which presented itself many years ago in London, recently occurred here, and occasioned no small scandal in the academic world. Seven medical students, many of them connected with highly respectable families, were tried for forgery of public documents,—a crime much more severely punished here than forgery affecting a private individual.

Two persons of education,—one a young man named Paulus, of 22 years of age; the other a Professor, named Charvin,—had long carried on a profitable speculation in procuring for the students the diploma of "Bachelor of Letters," which each student is bound to take out before matriculation in medicine. Paulus, from his youth and the extreme juvenility of his figure, was well calculated to represent the candidates. This he did with success and under various disguises, sometimes passing three or four examinations a day. M. Charvin completed the diplomas, by counterfeiting the necessary signatures. The trade flourished, it seems, for a long time; but a lynx-eyed Examiner at last saw through the disguise of M. Paulus, and the conspirators were arrested, with five diplomas in their pockets. Paulus was condemned to five years' imprisonment; Charvin, to three; and the five students let off, in consideration of their youth and inexperience.

LIGATURE OF THE PNEUMO-GASTRIC NERVE.

An unfortunate case, which from its misadventure becomes highly interesting, recently occurred in the practice of M. Chassaignac.

A woman, labouring under cancer of the velum palati, presented herself at the surgical consultation, and it was decided to try the chances of an operation. As the cancerous matter seemed to extend considerably beyond the walls of the velum, it was thought prudent to tie the carotid artery as a preliminary measure. This was done; but as the *post mortem* proved, the nervus vagus was included in the ligature, and the woman died on the eighth day. Neither the functions of respiration or digestion were in the least disturbed; but the voice was immediately extinguished.

The physiological considerations to which the foregoing case gives rise are at once important and interesting. It is not often that we have an experiment of the kind, with its results on the human body; and the above throws much light on the functions of the eighth pair, which have been differently interpreted by different physiologists.

Legallois, for example, affirmed that ligature of this nerve, near its origin, suddenly arrested respiration; and Percy held, with equal certainty, that the *primum mobile* of all the respiratory movements resided in that part of the medulla oblongata, (the restiform bodies,) whence the roots of the eighth pair take their origin. Lastly, M. Flourens, after a series of careful experiments, decided that the respiratory tract of the medulla was limited, superiorly, just above the origin of the eighth pair, and, inferiorly, about three lines below the origin.

M. Serres, in his treatise on comparative physiology, connects the movements of the heart with the olivary bodies, those of the lungs with the restiform bodies, and those of the stomach with the band which separates the olivary and restiform bodies.

Majendie's experiments would lead to the conclusion that section of the vagus has no influence on the movements of the stomach, while Bichot affirmed, that irritation of one or both of these nerves caused the stomach to contract. Tideman and Gmelin attribute the movements of the stomach to the eighth pair, and M. Breschet, as well as M. Edwards, excited muscular contraction of the organ by electricity or mechanical irritation of the pneumo-gastric.

Finally, M. Longet excited evident contraction of the stomach in dogs by galvanic or mechanical irritation of the nerve. Now, in the case related by M. Chassaignac, neither of the functions of the lungs or of the stomach were disturbed in the slightest degree; but the power of articulating sounds was immediately annihilated, and the case, moreover, proves that we cannot apply to the human subject the result of physiological experiments performed on inferior animals—a truth too often overlooked by the disciples of the Majendie school.

INOCULATION OF THE VENEREAL DISEASE.

M. Diday, late head surgeon to the Venereal Hospital of Lyons, has addressed to the two Academies a long, and, in many respects, curious memoir "On Process of Vaccination calculated to preserve Patients from Constitutional Syphilis."

The process consists simply in inoculating the patient with the blood of a person labouring under tertiary syphilis; and the author regards the effects of this inoculation as preservative from the constitutional disorder. It is unnecessary to say, that the patients affected with primary syphilis, and inoculated as above mentioned, were abandoned to nature without any species of constitutional treatment whatever.

Sixteen persons were treated in this manner. The local effects of the inoculation were insignificant. The chancres and bubos, dressed in the usual manner, healed as ordinarily, without presenting anything worthy of notice.

In order to obtain accurate details of the results, M. Diday followed the cases with the utmost care for many months, and the following are the results of his investigations:—Of the sixteen patients, fifteen remained free from any trace of constitutional taint up to the present time, that is, for a period varying from six to fourteen months after inoculation. As to the single case of exception, it may be remarked, that this patient was inoculated by mistake; in fact, he laboured under indurated chancre; and M. Diday makes it a rule not to inoculate any patient affected with this species of chancre, because he regards the induration as a certain sign that the constitution has been tainted. For the same reason he does not inoculate after the sixth day. The experiments of the Author are not on a sufficiently large scale to enable us to draw from them any positive conclusion; but the method certainly deserves trial. It is difficult to admit a mere coincidence. Hunter affirms, that hardly one patient out of fifty escapes secondary symptoms, if the chancre be treated locally only. M. Cazenave thinks, that eighteen out of twenty will have them, unless mercury be used. Cullerier asserts, that a moiety of non-indurated chancres are followed by constitutional effects. Most writers on the venereal disease adopt the same views; and when we remember, that the patients of M. Diday were for the most part soldiers on leave, and characters of an abandoned kind, exposed to all the causes which develope constitutional symptoms, it is difficult to conceive that their absence was a mere coincidence. But time alone can tell.

LITHOTRITY BY THE PERINÆUM.

M. Bouisson, Professor of Clinical Surgery to

the Faculty of Montpellier, proposes this mode of operating in certain cases where it is impossible to arrive at the bladder through the ordinary channel. He relates two cases in support of his views. One refers to a merchant, labouring under stone, who had already undergone the operation of lithotomy. The results of this operation, which appears to have been badly performed, were a fistulous opening in the membranous portion of the urethra, and two strictures, one in front of the fistula, and the other close to the prostate. The patient, moreover, had a second calculus, and his bladder was in a very bad state.

After preliminary treatment, M. Bouisson passed an instrument through the fistula, and easily crushed the stone; but the cure of the fistula presented many serious difficulties. It was necessary to force an artificial passage through the strictures, which were nearly cartilaginous, to remove the callous edges, and practice suture of the urethra. The latter operation succeeded, and the patient was cured after a very protracted treatment.

The second case was one of a similar kind,—a vesical calculus, complicated with stricture, at the curve of the urethra and perineal fistula. As in the former example, the calculus was crushed through the fistula, and, as the latter was not cartilaginous it was more easily cured by dilatation. The healing of the fistula took place under the permanent use of bougies, and touching its edges with the nitrate of silver.

GERMANY.

INFANTILE TYPHUS.

In the *Archiv fur Physiologische Heilkunde*, as quoted from the *Gazette Medicale*, Dr. Friedleben has given the results of his experience of four epidemics of infantile typhus; the first extending from February to April, 1844, and from July to August in the same year. Then in January and February, 1846, and during July and August of the same year. During the months of January and February, 1846, typhus was confined almost exclusively to children, affecting the adult more particularly during April and May. In the course of the three years, 1844, 1845, and 1846, the Doctor had under his charge 1842 children (880 boys and 962 girls), of which 98 cases were typhoid, to wit, 46 boys and 52 girls. Among these only one was under one year, 23 ranged from two to five, 32 from five to eight, 22 from eight to eleven, 12 from eleven to fourteen, and 8 above fourteen. The endemic, therefore, fell with its greatest force on children between the second and eleventh years; and was more prevalent in winter and summer, than in the autumn and spring.

The pathological character of this disease is detailed with great fidelity, and all the organic derangements of the intestinal canal, the lymphatic glands, the liver, the spleen, the kidneys, as well as of the circulating and respiratory system, and of the brain, are faithfully described.

The glands of Peyer, were much swollen; some of them being a line and a half in thickness. The swelling was not, however, always uniform,—the centre being frequently more elevated than the margins. Their surface was unequal, owing to the presence of capsules, which gave them the appearance of ulceration. The number of the diseased glands varied from six to twenty. They were of a bluish, livid tint, soft, and easily detached. No change seemed to have occurred in the other coats of the intestine, with the exception of the sub-glandular cellular tissue, which presented the appearance of softening. Such were the appearances noticed in cases which proved fatal before the twenty-third day. When disease was protracted beyond that period, induration of the glands occurred.

According to the opinion of the author, all the glands which became developed before the twenty-first day were the soft; those later, the hard. His observations establish the views of MM. Rilliet and Barthez, as also those of Barrier on the progress of inflammation of the glands. Severe ulceration of these may occur in exceedingly young subjects; they were witnessed in a case only two years and a half old. They may take place at a very early period, even on the eighth day, but cicatrization does not begin before the twenty-first day; its progress is found to be more rapid than in adults.

The mucous membrane is usually sound, being changed in appearance only in the immediate vicinity of the glands. In one instance, the mucous membrane of the stomach was observed to be inflamed. The sub-mucous cellular tissue was always natural. Changes are invariably discovered in the mesenteric glands; they are usually red and swollen, particularly at the beginning of the disease; infiltration and softening is rare: and, in the opinion of the author, the former only occurs in very serious cases, where there has been disorganization of the condition of the blood.

The general conclusions are as follows:—

1. The glands of Peyer, and as a consequence the mesenteric, are the local seat of infantile typhus.
2. During the first three weeks there is only simple inflammation of the follicles (plaques molles).
3. This (plaques molles) may terminate in resolution without ulceration; when this takes place, it gives rise to the first form mentioned in the paper.
4. The progress of the cicatrization of these ulcers is very rapid.
5. When the morbid action extends beyond the twenty-first day, infiltration of the glands of Peyer may occur, (plaques dures.)
6. The infiltration begins in the glands in the proximity of the great intestine.
7. This leads necessarily to ulceration, constituting the second form of ulcerations.
8. Cicatrization takes place very slowly in these last.
9. After the twenty-first day, the two modes of ulceration may be discovered united together.
10. In all the cases terminating favourably, and in the generality of those ending in death, the mesenteric glands are only affected by a simple inflammatory softening.
11. The changes of the spleen are simultaneous with those above described.
12. All the complications which happen before the twenty-first day, are of a very distinct inflammatory character.
13. The chemical character of the blood agrees with that state.

Hence the corollary is obvious, that infantile typhus for the first three weeks consists essentially in follicular inflammation of the intestines, which readily admits of cure, and is essentially distinguished from the typhus of adults.

SCOTLAND.

[From our own Correspondent.]

Our curiosity is much excited to learn more of the supposed fungus vegetable bodies described as being found in cholera discharges, and in the atmosphere and water of the localities where pestilence prevails. We are all much pleased with the judicious remarks in the two last Numbers of the *Medical Times* on this still so doubtful discovery. Besides the Bristol observers, Brittan, Budd and Swayne, we see two new converts to the subject have appeared, Dr. Baly of the Millbank Prison, and Dr. T. Williams, of Swansea; nor does the non-medical Correspondent of the *Medical Times*, the civil engineer, Mr. Gilbert, pass unnoticed. Dr. Baly's observation is of considerable moment, showing bodies of a similar, though not of the same figure, in dysentery; and his observation will be of still higher importance, if the bodies which he has described be determined to be absent in sporadic dysentery, and to be present only in epidemic dysentery. It is, however, far from being a settled point, that either the cholera bodies or dysentery bodies are truly vegetable organisms, and the pertinent questions in the *Medical Times* of September 29—1, as to their existence in all cholera discharges; 2, and in all cholera localities; 3, as to their absence in all other diseases; 4, and in all localities where there is no cholera,—have still to be answered in the affirmative.

Our microscopic pathologists here have not been idle since intelligence of the Bristol views reached Edinburgh; and we believe an investigation of the microscopic bodies discovered in the dejections of cholera patients, and in the air of our chief cholera hospital is already so far completed, that their various forms have been successfully delineated, and that the second not less essential step, namely, the search for the same or similar bodies in the corresponding discharges of persons in health, or affected with other diseases, is also commenced, and likely to be carried on with the requisite diligence.

In the mean time, discourse runs on the greater or less probability of this investigation leading to any definite result. All are agreed, that Dr. Budd has not shown himself much of a philosopher in the *Times* newspaper. The decision of the question, even if these bodies were already proved to be distinct vegetable organisms, and if all the questions before referred to were already answered in the affirmative, would still be attended with very great difficulties. In short, numerous obstacles will arise before we can reach the satisfactory conviction, that minute vegetable organisms floating in the atmosphere, or contained in the water which we drink, constitute the definite exciting cause of cholera in the same sense in which a peculiar virus is the exciting cause of small-pox. There is nothing analogous to such an hypothesis in the whole etiology of diseases. Such a cause cannot act in a manner analogous to any of the known poisonous fungi, because, not to speak of the difference in the bulk of a myriad of such invisible organisms, all who breathed the air, or drank the water of the affected locality, though they might escape the fully-developed type of the disease, would at least show some signs of having been subjected to the poison. All probability is, therefore, against the reality of such a cause, because the assumption implies a striking anomaly in the course of nature. Thus, the mere co-existence of these fungi with cholera, thought it were proved exclusive, neither proves such an agency to be the cause, nor even renders it likely to be the cause. We are far from saying, that the want of probability is a sufficient ground for rejecting such an agency, after its exclusive co-existence with cholera is satisfactorily proved; but this want of probability compels us to seek stronger evidence than would suffice were there distinct analogies in its favour. The parallel insect theory of the origin of certain diseases has existed for more than two centuries. It can boast of many supporters of high name since the days of the Jesuit Kircher, who seems to have first broached it. In the last century, Linnæus was among its zealous supporters, and of living authorities in its favour it numbers at least one practical physician of sober judgment, Dr. Henry Holland. Dr. Holland endeavours to show that the influence on which the spread of cholera is dependent corresponds with the laws governing the diffusion neither of purely physical agents, nor of vegetable bodies, but only of animal existences. But, what progress has the insect-theory made? After an existence of more than two centuries, it is still in embryo, and there is not much more promise in behalf of the theory of the vegetable origin of cholera.

Finances of the College.—From the report just published of the receipts and expenditure of the Royal College of Surgeons, it appears that in the year, from the 30th of June, 1848, to the 30th of June, 1849, the former amounted to 9366*l*. 19s. 5d., derived from the fees of admission to the Fellowship, Membership admission to the Council and Court of Examiners, and sale of collegiate publications; inclusive also of the sum of 653*l*. 17s. 6d., paid for the old materials of the warehouse, purchased of Alderman Copeland. The disbursements amounted to 9243*l*. 14s. 1d., being within 123*l*. 5s. 4d. of the receipts. From the above, it appears that the incidental income is 8415*l*. 16s. 2d.; the expenditure, 5636*l*. 19s. 7d.; the permanent income, 951*l*. 3s. 3d.; and the permanent expenditure, 3606*l*. 14s. 6d.

Complaints having reached us of the irregular delivery of the MEDICAL TIMES *in the country by the Booksellers and Newsmen, we state, for the information of our readers, that this Journal is always published early on Friday afternoon, so that it may reach the Provinces by post on Saturday morning.*

TO SUBSCRIBERS.

New Subscribers will oblige by forwarding their Names direct to the Office, 147, *Strand, or to the News Agents or Booksellers. All Post-office Orders should be made payable to the Publishers,* WM. S. ORR AND CO.

THE MEDICAL TIMES.

SATURDAY, OCTOBER 13, 1849.

EVERY public journal of weight and influence has, during the last year, directed attention to the fact, that the crime of secret murder is fearfully great, and, among the many suggestions which have been offered in the hope that a check might be put upon this enormity, those only are of value which are based upon a belief that the crime owes its origin to what is aptly termed the uncertainty of detection. Fully persuaded of this, Mr. Coroner Payne and his professional brethren are for having more inquests; while we, possessed of a like amount of conviction, as regards the first element of their creed, are for having those inquests better conducted. They should, in truth, be inquiries, founded, in great part, on the experience and knowledge of the Medical Practitioner, and guided by all the lights which medical science is capable of throwing upon the subject. Under such circumstances, we feel convinced, that the records of the Coroner's Court would furnish but few instances of error, and still fewer of such unsatisfactory verdicts as "Death by the visitation of God," "Found dead," and so on; but, on the contrary, the results of the Coroner's investigations would be so absolute and certain as to inspire the criminal with dread and the public with confidence.

In order, however, to effect this desirable object, one of the first and most essential conditions, is a better remuneration for Medical witnesses, and a fuller application of the extensive powers of Medical Science; for at the present time there is scarcely one inquest out of three, in which the services of the Medical practitioner are at all demanded: and, notwithstanding the Act relating to Medical witnesses states, that "whenever, upon the summoning, or holding of any Coroner's inquest, it shall appear to the Coroner, that the deceased person was attended at his death, or during his last illness, by any legally qualified Medical practitioner, it shall be lawful for the coroner to issue his order for the attendance of such practitioner as a witness at such inquest; and if it shall appear to the Coroner that the deceased person was not attended at or immediately before his death by any legally-qualified Medical practitioner, it shall be lawful for the coroner to issue such order for the attendance of any legally-qualified Medical practitioner, being at the time in actual practice in or near the place where the death has happened;" yet the Coroner is, in many instances, accustomed to rely upon very shallow evidence furnished by non-medical witnesses, in order that he may, on the one hand, make a show upon the face of his proceedings; and, on the other, save the county from those expenses which are absolutely necessary to the proper elucidation of the case; for the law states—

"1st. To every legally-qualified Practitioner, for attending to give evidence under the provisions of this Act, at any coroner's inquest whereat no *post-mortem* examination has been made by such Practitioner, the fee or remuneration shall be one guinea.

"2nd. For the making of a *post-mortem* examination of the body of the deceased, either with or without an analysis of the contents of the stomach or intestines, and for attending to give evidence thereon, the fee or remuneration shall be two guineas."

But, poor as this pittance is, the payment of it is, as we have already said, avoided upon all occasions, and upon all sorts of pleas; sometimes because the Practitioner has not received a Medical summons; and at others, because he has made an examination of the dead body without an especial order; for according to one of the provisions of the law, "it is enacted, that no order for payment shall be given, or fee or remuneration paid, to any Medical Practitioner for the performance of *post-mortem* examination which may be instituted without the previous direction of the Coroner." So that the efforts of the Medical Witness are often greatly checked by the knowledge, that no remuneration will follow upon any kind of services which have not been ordered and directed by the Coroner.

Again, there is a manifest deficiency in those portions of the Act which relate to the duties of the Medical Witness; for it is therein merely stated, that the Practitioner shall make an analysis of the contents of the *stomach and intestines*. Now, the progress of chemical science has clearly shown, that, in by far the greater number of cases of poisoning, the *corpus delicti* is to be found, not only in the contents of the stomach and intestines, but also in the general tissues of the body; and, in order to elicit this, which is by far the most conclusive part of the chemical evidence, inasmuch as it proves that the poisonous agent has really been absorbed, and must, therefore, have gained access to the body during the life-time of the individual, it is necessary to make an elaborate chemical investigation, which requires time, expensive materials, and great tact. But such a process of research is not provided for in the Act, and is not, therefore, compensated by any remuneration allowable by law. Moreover, it is not, by any means, an unusual circumstance for the Coroner to require the additional services of the Medical Practitioner in ascertaining the nature of other matters than those found in the dead body, in order that he may be enabled to determine the source of the poison, as well as the fact of its having been administered; but for such investigations as these the law has has made no provision; on the contrary, let the inquiry be as extensive as it may, it limits the fee to two guineas; and the Magistrate is ever absolute in preventing the Coroner from giving a greater sum than this,—consequently, in many cases, the Practitioner is compelled, either to forego the complete investigation of the matter, or, undertaking it, he must trust to the chance of a Judge's order for an equitable remuneration.

Such a condition of things demands an immediate reform, and yet we hardly know how so desirable an object is to be effected; perhaps however, a somewhat positive bearing on the part of the Medical Practitioner may in time lead to it; for, as all inquests are instituted for the purpose of ascertaining the cause of death, they can hardly ever be considered as complete, without the testimony and opinion of a Medical Practitioner. In all cases, therefore, in which an inquest has been conducted without the employment of such testimony, the Medical Man is bound to communicate either with the Coroner or the Secretary of State respecting the omission.

Again, on making a *post-mortem* examination of the body, should the Medical Practitioner suspect from the nature of the symptoms, or from the appearance of the viscera, that poison has been administered, it is his duty to transfer certain portions of the body with all care into the custody of some one who is well versed in chemico-legal researches; by which means he will, without endangering either his reputation or his fee, save himself from the expense and responsibility of a chemical analysis; for it is provided, that "whenever it shall appear to the greater number of jurymen sitting at any Coroner's inquest, that the cause of death has not been satisfactorily explained by the evidence of the Medical Practitioner, or other witness or witnesses who may be examined at the first instance, such greater number of the jurymen are authorised and empowered to name to the Coroner, in writing, any other legally qualified Practitioner or Practitioners, and to require the Coroner to issue his order for the attendance of such last-mentioned Medical Practitioner or Practitioners, as a witness or witnesses, and for the performance of a *post-mortem* examination, with or without an analysis of the contents of the stomach or intestines, whether such an examination has been performed before or not; and if the Coroner, having been thereunto required, shall refuse to issue such order, he shall be deemed guilty of a misdemeanour, and shall be punishable in like manner as if the same were a misdemeanour at common law." And, therefore, in giving testimony in such a case, the Medical Practitioner will always do well to confine himself strictly to the symptoms and *post-mortem* appearances, leaving the chemical part of the inquiry to some one who is practically conversant with the difficulties connected with it. By this means he will be doing his best to forward the ends of justice, not only as regards the issue of the case itself, but also as regards the matter of Medical remuneration; and he need not fear that the fees will be withheld by the magistrate, for it has lately been decided by Lord Denman, in the case of the "Queen *versus* the Justices of Carmarthenshire," that magistrates have no control whatever over the legal fees paid by the Coroner out of his own pocket, and this functionary can, therefore, employ as many Medical witnesses,

in any case, as the jury may deem necessary for the elucidation of it.

TESTIMONIALISM.

We live in strange times and witness strange events. States are convulsed—empires are overthrown—every class of the community is in constant agitation, either for the purpose of maintaining its rights or extending its influence. The age of repose, or of quiet and contemplative enjoyment, is past. Amidst a vast amount of wealth, and of the command of luxuries hitherto unknown, society is heaving to and fro from intestine commotion. Analyse any of its divisions—the manufacturing, the commercial, or the professional—and each will present an accurate picture of the whole.

In former times, the acknowledged scientific attainments of an individual, and the implied requisite moral qualities, rendered him an eligible candidate for any office to which he aspired. He never dreamed of the necessity of obtaining, from his intimate friend, a written character, stating, in glowing terms, what an admirable husband and parent he was:—how exemplary in all the relations of life—how assiduous had been his application to Professional pursuits—how dearly he was beloved by all who had the honour of his acquaintance—how much the proposed change in the field of his exertions would distress his immediate friends—and what a void would be left in the social and intellectual circle by his removal; nor did the candidate apply to his pastor, to certify, that he had long occupied a pew in his church, and was extremely regular in his attendance, and correct in the discharge of his religious duties. All these things were unknown. They are the offspring of a new order of affairs; and well, indeed, it would have been for the dignity of the Profession, and the self-respect of the candidates themselves, if the idea of a recourse to such practices had been treated with deserved contempt.

The prevailing complaint among the Profession themselves, is the constant deviation from strict professional usages,—a tendency towards the adoption of means thoroughly commercial in letter and in spirit; laying aside all delicate and fastidious considerations in harmony with the importance, the requirements, and the character of the healing art. The professional man is naturally taught to feel that he is not a trader, nor ought he to be lowered in his own or the estimation of others, by practices which have not hitherto been recognised as honourable. The porter, the cook, and the matron, and every needy aspirant to a vacant office, accumulate testimonials in favour of their honesty, probity, and fitness to discharge its duties. This is all right and unobjectionable. Their position in life does not necessarily imply the possession of these qualities. But what are we to think of the members of a learned Profession—men who have established a respectable *status* in the estimation of the public by works of deserved reputation, so far forgetting themselves, as to apply to almost every one whom they knew, and even to those to whom they were personally unknown, *for a certificate of character?* Surely such things have not come to pass. This must be a dream—a suggestion of what is possible in the future. It is, however, a real fact, and one which will not readily be forgotten. A vacant Chair of St. Andrews, worth 300*l*. per annum, has brought into the field five Candidates, Drs. Day, Paterson, Redfern, Harvey, and Glover.

All those gentlemen have excellent qualifications, and claims worthy of consideration; and they have actually deluged Edinburgh and St. Andrews with books of testimonials, of such magnitude that they would cause indigestion, if waded through after a comfortable repast. We have *first* and *second* editions, and, if the struggle had been much longer protracted, every printing press in our beloved and classic city of Edinburgh would have been fully employed in furnishing a lengthened series of new certified characters. We hope that the College authorities in future, will consider the advantage that it would be to trade, if they allowed such contests to continue for, at least, twelve months. We throw out the hint, and many worse have been suggested.

Is not this a strange picture of the existing state of the Profession, when members of it of decided talent, of acknowledged ability, and whose scientific labours are evidence of it, publish almost volumes of letters in reference to *their moral, social, and mental fitness?* This, indeed, tells of the degrading expedients and calculations of trade.

We regret that there was not one among them that dared to assert the dignity of his position—his right to consideration from what he had done as a scientific inquirer;—an exception of this kind would almost have redeemed the erring proceedings of the whole. The example would have been of high value, and would have stood out, on subsequent occasions, whatever might have been the result, in bold and proud relief to the dead flatness of common and humiliating conduct.

If these gentlemen do not feel that they are degraded in their own estimation, they are wanting in a refined sensibility of their own worth, and have certainly no fastidious sense of the delicate proprieties of professional life. They, however, are not alone to blame. Those who have written the testimonials are equally in fault. Out of the hundreds applied to, one had the independence to refuse the request, and on the ground, *that such a system was bad and derogatory to the Profession.* What are nine-tenths of the testimonials worth, furnished on such occasions? To impart any value to them, they must emanate alone from those who, from their station, admitted talents, and scientific reputation, have the privilege to express an opinion. It is preposterous and absurd for men generally to imagine, that they have an importance sufficient to entitle them to exercise the right. Before they presume to do this, let them first establish a position for themselves. To appreciate the abilities and fitness of others for any office, it is necessary to be a *judge* of those abilities, and of their aptitude to discharge the duties of it. And these cannot be justly estimated except by those who are among the *élite* of the scientific, and who have given evidence of the possession of commanding talent. An analysis of the mass of testimonials lying before us, does not present generally the required qualities in those who have thus stepped out to record their individual sentiments. A respect or admiration for the talents of our friends may induce us to pass the sober bounds of delicacy in executing the disagreeable task of recommendation; but what is the value of an opinion derived from such sources, flowing from the heart, and not from the well-furnished or enlarged understanding? It is not worth the paper on which it is written. Some of the gentlemen called upon for an eulogy—for a letter of credit—say, that the best Testimonial they can give, *is the regret they will feel in the loss of the society of the candidate,* should he be successful in the attainment of his object. What nonsense! What relation has their regret to the onerous duties of the office, or to the peculiar fitness of the person to perform them efficiently? Had the Testimonial been given to introduce the candidate to some wealthy capitalist, as one in every way worthy of drawing upon his coffers, it would have been in excellent taste, and might possibly have substantially served him.

The consideration of this system of Testimonialism, and the extent to which it has been carried, on the present occasion, are suggestive of thoughts we cannot well suppress. All the candidates are pretty equally lauded. In praise of them, the English language has been nearly exhausted of its superlatives, and, at the same time, of its choice and comprehensive words. There never were such men, and probably will never be again. In morals and social qualities, they are perfection. In understanding, they have every rare and distinguished faculty; studious and enterprising in the acquisition of knowledge; displaying large and original views; eminent for their practical abilities; fluent, eloquent, persuasive, and impressive, in their public discourses,—awakening in all who come within the sphere of their influence, sentiments of admiration and unutterable feelings of esteem; standing high in official medical appointments, and universally known as the fortunate possessors of this unequalled combination of unequalled excellences. Is this enough? We have not half drawn upon our resources—the testimonials lying upon our table. We have said nothing of the kindness of heart, or of the amiable disposition of the individuals; how much they are endeared to all who know them; nor have we alluded to the pew which they adorn and occupy with exemplary punctuality, or to that invaluable talent of innoculating those who attend their lectures, with the same enthusiastic spirit of scientific research by which they are animated, leading them by short steps from the discovery of one grand truth to another. This, after all, is an inadequate description of the claims of the candidates, as attested by hundreds of *unbiassed and competent judges.*

The contemplation of these qualities places us in a dilemma, which offers only three ways of escape. The chair which is vacant yields 300*l*. per annum. This is the pecuniary value of the object of their ambition; and its locality is a small, obscure city, that has got prematurely old,—outlived its once respectable reputation, and like some of the softer sex, in its advanced years, has been much neglected by

the rising generation, almost unnoticed, except, on these extraordinary occasions, when th good old lady creates a few ardent admirers by the glittering bribe which she temptingly displays.

To return, however, to the consideration o: the subject, in a mood in accordance with its importance, we would ask, Are we to believe these Testimonials? Are they strictly correct in their representations, or are they a gross exaggeration of ordinary mental qualities? We suspect, and we have some ground for our suspicion, that Sir David Brewster has distributed among the friends of the candidates some of his admirable kaleidoscopes on a large scale; and, instead of their usual contents—bits of coloured glass—the aspirants themselves have been placed in them by their respective admirers. Hence the beautiful and unequalled forms which have broken upon the view, on every slight and anxious agitation of the materials. Constant variety, but always variety in its highest excellence. Sometimes the seductive qualities of the heart arrested the attention in warm and glowing hues; at another time the mind, in a halo of light extending far into the future, fixed the observer in a trance, by the lavish display of the rich fruits of genius—important scientific discoveries—seizing Nature in her secret operations, and dragging her, thus caught, into open day; another agitation of the instrument presents an endless group of friends surrounding the candidate of their choice, and, by their expression, luxuriously enjoying his social qualities, and listening in raptures to his fluent and eloquent tongue; but their countenances occasionally saddened at the thought, that his success would be his removal to another scene of action. No one knows (except ourselves) what the genius of Sir David Brewster has done in this matter; and where does his genius not leave an impression of its brilliancy and power! He is himself a magnificent kaleidoscope, constantly presenting variety, beauty, and excellence to our view. He is an honour to his country, and one of the few that will transmit an imperishable name to distant times.

This, however, is an episode. If the candidates possess these extraordinary excellences, combining the accomplished chemist, the practical physiologist, and experienced physician with numerous other professional adjuncts, and crowds of admiring friends: how does it happen *that an income so limited*, after years of study, toil, and scientific research, with a reputation for every virtue under heaven, should be worthy their ambition? Let those who contemplate entering the Medical Profession ponder well on these matters. They are full of significance; and the painful truth with which they are fraught lies naked upon the surface. The plain fact is—and why disguise it? one of three conclusions forces itself on the mind:—the public have not appreciated their claims; that the Profession abounds in men of the same mental calibre; or, which is much nearer the truth, their abilities have been greatly exaggerated. They are all men of unquestionable respectability, some possessing more than an average of talent; but they have been so ridiculously caricatured by their friends and admirers, that it is difficult to form a sober estimate of their worth.

The testimonials, generally, are a curiosity in a literary point of view; and if the judgment of some of those who penned them, is to be estimated by their knowledge of the English language, it is certainly not particularly distinguished for its soundness.

THE OPERATIVE SURGERY OF JOHANN FRIEDRICH DIEFFENBACH.

CHAPTER IX.

THE LIGATURE OF ARTERIES.

Ligatura Arteriarum.

The ligature of an artery implies the tying of it with a thread in order to interrupt the circulation of the blood and effect its obliteration. The purpose of the operation is either the arrest of hæmorrhage from a wounded vessel, or the diversion of the flow of blood from a diseased artery, as in aneurism, or he diminution of morbidly-augmented development, as in the instance of tumour.

Although Celsus has the merit of being the inventor of the ligature on wounded arteries, Paré was the first surgeon who inculcated the importance of the practice.

The action of the ligature upon an artery is a sudden stoppage to the passage of the blood which stagnates between the ligature and the nearest collateral branch; but eventually continues its course, by anastomosing branches situate above. When an artery is properly tied with a thin waxed silken thread, the internal and middle coats are cut through, and the cellular tunic contracted to a fine puckered fold. The stagnating blood coagulates and forms a cone, of which the base is towards the site of the ligature, while the apex extends to the first collateral branch. This cone is progressively absorbed, and there just remains sufficient of the plastic contents to bring about the adhesion of the inner surface in connexion with the effusion from the walls of the inflamed part. Under such circumstances, the vessel appears as a solid band. The outer surface of the artery is bound to the adjunct parts by inflammatory exudation, resembling a thick ring, which intimately incloses the thread, but allows its end to pass through. After a while the thread, by giving rise to suppuration, is ejected as a foreign body.

Ligatures produce very different effects, according as they are thin and round, or thick, flat, and broad; and according as they are applied, firm, loose, or moderately tight. The study of these phenomena is one of the most interesting in experimental physiology. As far as practical surgery is concerned, the invention of the ligature upon arteries is quite as important as was Harvey's discovery of the circulation of the blood in reference to physiology.

The tying of arteries is chiefly resorted to, as a certain means of suppressing hæmorrhage from wounds, and operations where it is sometimes performed as a preliminary step; in the cure of true and false aneurism; for the purpose of diminishing the flow of blood to a hypertrophied part, in order to check nutrition, as for example putting a ligature on the thyroid artery in the case of bronchocele, and on the internal spermatic artery in case of sarcocele.

There are two principal modes of applying the ligature. One is the insulated tying, in which the artery previously cleared from the surrounding cellular texture, is engirt with the thread. In the other, the artery and adjunct textures are all included in the ligature, which causes a swelling both above and below the noose.

As in the insulated or immediate ligation too violent tying of the noose may divide or cut into the vessel, and thus occasion bleeding; so likewise the mediate may be followed by dangerous nervous seizures, phlebitis, and the like, in consequence of nerves or veins being comprised within the ligature.

I. OF THE INSULATED LIGATURE.

The insulated tying of an artery is accomplished with a waxed thread of twilled silk, half an ell long. A light spring forceps, with moderately broad nibs, is best adapted for taking up the artery. While the assistant presses promptly and firmly a soft moist sponge against the wounded surface, so as to render the vessel conspicuous, the surgeon seizes the latter longwise with the forceps, draws it a little out, and holds it fast, until the assistant places the noose of the ligature round it. The noose having been properly adjusted by means of the fore-fingers, is to be tightened. The forceps are next withdrawn and a knot made.

This is the most easy and natural mode of tying an artery. Should the bleeding be very violent, and the vessel remain concealed in spite of assiduous sponging, the surgeon, with a forceps in each hand, directs his scrutiny to that part of the wound where the blood issues, lays hold of a fold of flesh with one of the forceps, which shall include the artery, raises it a little up, has it dabbed with a sponge, and with the other forceps secures the artery thus brought into view. A ligature is then to be applied, care being had that it involve none of the surrounding textures. Some surgeons think to facilitate the operation by previously placing the knotted thread in a wide noose upon the forceps, then seizing the vessel, and drawing the noose. This, however, only increases the difficulty. The thread gets soaked with blood before it can be tied, and the knot is less firm.

Voluminous arteries when divided as in great amputations, are most conveniently taken hold of by inserting one blade of the forceps within the vessel, while the other remains without. One side being thus secured, the vessel is drawn out, grasped with the second forceps, and then tied.

The tenaculum may be employed as a substitute for the forceps in the instance of hæmorrhage from solid textures, where it would be a difficult matter to insulate the artery with the latter instrument. It is also available in bleeding from deep wounds, as for example after the extirpation of glands from the axilla. Here a portion of the lower part of the wound may be taken up with a thick, sharp hook, the vessel then seized with forceps, and encircled with a ligature.

Every variety of aid is required in case of severe hæmorrhage. Intelligent assistants must hold the lips of the wounds apart with their hands and with blunt hooks, allow a gush of cold water to fall from a sponge over the wounded surface, squirt a full stream of water from a large syringe upon the spot from which the blood is welling forth, exercise pressure over the main trunk of the vessel, and relax it at intervals, until at last all obstacles are surmounted, and the ligation of the artery achieved.

If an artery is merely incised, and the blood jets from an opening in the side, it will be necessary to tie it both above and below the opening. The thread is to be passed underneath the vessel with a hook having an eye at the point. Sometimes, the artery may be completely cut across, in which case both ends should be tied. The ligation of arteries is the best study for young operators, who cannot become too early initiated in all its practical bearings. They thus acquire readiness, coolness, and courage, for the dread of cutting is less than for its consequence—the loss of blood; and he who feels himself thoroughly capable of controlling hæmorrhage, will invariably handle the knife in a steady and collected manner.

Nothing can show better the difficulties which occasionally beset the tying of arteries, than the numberless instruments in the shape of forceps which have been contrived for the purpose. Many of these are highly ingenious. Few, however, are worth noticing, with exception of Graefe's spring-forceps, and Fricke's torsion forceps furnished with a slide. Either may be employed when there is no competent assistant at hand. The artery being se-

cured, the forceps is locked by means of the spring slide, and then given to a bystander to hold, or re tained by the surgeon in his mouth, until the noose is tied round the vessel.

II. OF THE MEDIATE LIGATURE.

This is performed with a fine bent-hafted needle, and a thin waxed thread. The vessel, together with the adjunct parts, is taken up with the needle, held between the thumb and forefinger in a semi-circular manner, or else wholly encircled by a second stitch and then the thread drawn into a noose, upon which a knot is to be made with both forefingers, and the ligature completed with an additional knot. In performing this operation, it is expedient to embrace as little as possible of the fleshy parts in the ligature, for the larger the circle which encompasses the artery, the more likelihood of considerable nervous fibres being included.

This mode of procedure is still one of doubtful propriety, to be undertaken only when the hæmorrhage cannot be otherwise suppressed, or the individual vessels tied separately. In parenchymatous bleeding, and in cases where the folds of texture from which the blood issues are either unusually lax or unusually firm, it is often the sole means of averting mischief. If the patient have already lost much blood, and is much exhausted, this plan ought, indeed, to be resorted to without delay.

After the knot is made, the threads are either shortened, so that they reach very little beyond the wound, or one end is cut close to the knot, and the other to within an inch of the knot, or, lastly, both ends are cut off close to the knot.

When both ends of the ligature are allowed to remain, they increase the amount of extraneous matter in the wound, and thereby impede direct union. The practice is therefore to be repudiated.

The second mode, in which one end is cut off close to the knot, is to preferred in all cases where immediate adhesion is intended.

The third mode, in which one end is cut entirely away, and the other to within an inch of the knot, is most eligible when the wound is large, the ligatures numerous, and the healing to be effected by the process of granulation. When several arteries are tied, the different threads are apt to get entangled about the edges of the wound and create inconvenience. This is best obviated by dressing with picked lint and a few strips of plaster.

The third mode, in which the practice of cutting off both ends of the ligature close to the knot is implied, was extensively employed by Von Walther, and described by Fraenkel (Diss. de laqueis arter.: delig. inserv. Bonn, 1824,) as also in Graefe and Walther's Journ., Vol. XIX. p. 303. It frequently admits of healing by first intention, and of permanent enclosure of the noose within a cyst; but very often after a long period has elapsed, a small abscess forms, and remains open until the remainder of the ligature has come away. Even in wounds repaired by the process of granulation, the noose is liable to be covered over with granulations, and detained by the cicatrice, to escape at some future time, as I have repeatedly witnessed.

The second and third methods seem to me the most eligible. The former in the instance of union by first intention; the latter in that of healing by granulation and cicatrization, because, before the wound is closed, the thread can be removed, by moderate traction, with a forceps.

Ligatures come away as extraneous bodies, after having divided the arterial tunics, in from six to ten days. If some of the adjunct textures are included, the division by the thread is not completed, and the ligature grows in, as is said; in other words, no sundering or suppuration occurs. Where the wound is still open and granulating, the hidden noose may be cut through and withdrawn by pulling forward one end of the thread with forceps, and inserting the points of fine scissors within the granulation. To remove it without cutting would occasion pain and bleeding.

The separation of ligatures from deep wounds, of which the edges are already adherent, takes place as above stated, nearly of its own accord, by gently drawing it along the sinus, so soon as the vessel that had been tied is severed. A small cup-like orifice, surrounded by delicate granulations, indicates, for a brief period, the site occupied by the thread, and healing ensues within a few days. After the long sojourn of thickly-twilled ligatures there remain frequently, even after they have come clean away, obstinate fistulous canals, which may require for their cure treatment by incision, or dilatation with sponge-tents. I have never found it necessary, in order to extract a ligature lying within a wound that is healed up, to introduce a director, divide the canal, and cut out the noose, as has been proposed; but have always succeeded by milder means.

When a long ligature remains stationary, I give it a gentle pull at each dressing, whereby slight inflammatory irritation is produced, which enables it to cut its way out. Should this fail, I pass the thread through a small, round, leathern disc, pierced with a hole in the centre, and noose the end of the thread round a little piece of sponge-tent, which is brought into close contact with the leather; over these a moist compress is placed, which causes the sponge and leather to swell up gradually and thereby exercise a progressive traction upon the ligature. Were a large portion of sponge-tent fastened within the noose, and covered with a wet sponge or a handful of moistened lint, the rapid distension would be followed by violent stretching of the thread, similar in effect to forcibly tearing it away with the fingers. Kluge recommended a rather complex procedure, namely, to lay on both sides of the thread two fragments of sponge-tent of the thickness of the finger, surmounted by two wooden chips attached by means of adhesive strips; over these crosswise a small stick, to the middle of which the ligature is fastened. As soon as the sponges become swollen from the secretion of the wound, or from moisture, they ease out the threads, generally in the course of twenty-four hours. This seldom requires to be repeated.

Early or late secondary hæmorrhage, emanating from section of the vessel, or from arteries left un tied, is to be suppressed by additional ligatures, plugging, and compressive bandages. Purulent deposits, and other casualties, are to be treated on surgical principles.

As concerns ligatures, I have stated above that a fine thin round thread is the most suitable, accord ing to the experience of practical surgeons. I have tied the largest vessels with fine silken threads, and with uniform advantage. Among the various articles which have been proposed at different times for this purpose, may be mentioned cat-gut, caoutchouc, lead and other metallic wires. But, as a general rule, nothing answers better than plain uncoloured silk twist or linen thread, previously rubbed with white wax.

OF TYING ARTERIES IN THEIR CONTINUITY.

In the foregoing section instructions have been given respecting the employment of the ligature for the stoppage of bleeding from divided or wounded arteries. In the present, the subject of tying large vascular trunks in their continuity, for the purpose of effecting their obliteration, and turning the stream of blood into the collateral branches will be discussed.

The operation of applying a ligature to the main trunk of an artery is resorted to in certain chronic diseases of the arterial system, in true aneurism, and in aneurism by anastomosis, also in false aneurism, acute as well as chronic. Further, in violent hæmorrhage, which is not to be suppressed on the wounded surface, even despite of dilatation, either because the main trunk is firmly contracted or punctured higher up. In a morbid condition of the vessels of the skin; and in the instance of arteries injured through compound fractures or gunshot. As a preliminary step in considerable exarticulations, in order to prevent the loss of blood. Lastly, as a means of cutting off an excessive supply of blood to hypertrophied parts, as in bronchocele, enlargement of the testicle, parasitic growths, medullary fungus, and the like.

It is first of all necessary to be fully cognizant of the situation of the vessel about to be tied, and to ascertain the pulsation during alternate tension and relaxation of the muscles, and under slight and strong pressure with the ends of the fingers. The rules given by Lisfranc and Malgaigne for discovering arteries are very useful. The division of the skin, as usually prescribed, is uncertain, because the artery may be readily missed. Wherever I can feel the artery, I place the thumb and forefinger of the left hand wide open, with the points upon the proposed extremities of the incision, and have the skin put on the stretch, from side to side, by an assistant. By this method the artery can never be missed. The cut through the skin must coincide with the longitudinal axis of the vessel beneath; if, however, the pulsation is indistinct and the individual so fat that the tract of the muscles cannot be followed, an oblong slanting incision may be made over the vessel, but not more than that one extremity shall extend to its left, and the other to its right side.

Should an aponeurosis cover the vessel, Malgaigne recommends its section laterally, so as not to injure the latter. This, however, is apt to produce a kind of lateral pouch, which confines the vessel, so that it cannot be well insulated. Puncture of the arteries and nerves is also more likely to happen than when the aponeurosis is merely opened in the line of the cutaneous incision. After the cut is made, prior to tying the artery, it is advisable to put the muscles on the strain, in order to get a better command of the loose space, and find the vessel. It is sometimes proper to draw aside a muscle overlaying the artery with a blunt hook or spatula. The cellular texture is usually detached with the chisel-shaped handle of a scalpel.

The artery can always be discovered by due attention to its anatomical bearings. There are everywhere definite indications. Thus, the subclavian artery lies at the external side of the tuberosity of the first rib; the crural artery in the middle of the thigh below the sartorius muscle, in the upper third to its inner, in the lower to its outer side.

During the operation the patient is to lie extended upon a padded table, with the head moderately elevated; according as the vessel is situate, will the position be prone, supine, or half on the side. A scalpel suitable for puncture as well as cutting, is to be selected. The handle is to be smooth and thin, that it may serve to separate the intermuscular cellular texture. The latter attached to the artery, is to be taken up with forceps in the common way, and slit with the knife, and the fascial sheath of the vessel opened like a hernial sac, with a whitlow-director, then the blunt end of the director passed into the orifice and the sheath divided along the groove. The edges of the skin and any muscles lying in the way are to be drawn asunder with blunt hooks or bent spatulæ, so that a distinct view may be had of the gap. Next follows the application of the ligature.

The operation is naturally divided into three periods. The first is the cutaneous incision; the second the exposure, and the third the tying of the artery.

1st. The incision through the skin is made in such wise, that the knife, held like a pen, is carried with its point perpendicularly through the skin, at the same instant depressed, and its edge made to divide, with one sweep, the skin and subjacent cellular texture. As above stated, the left thumb and forefinger indicate the two terminal points of the incision. It is only by means of a free clean cut penetrating deeply to the vicinity of the vessel, and clearing the lax subcutaneous cellular texture that a smooth simple wound is procurable. If the corium be merely severed, there result from nibbling with forceps, the frequent introduction of the director, and the partial lopping of a number of irregular portions of the surface of the wound, numerous little devious sinuses, and the risk of suppuration. The subsequent slitting of the cellular texture ought always to be made in the exact course of the cutaneous incision upon a director. Having, at length, arrived within range of the vessel, it can be distinctly felt pulsating through the intermediate parts; and also seen pulsating, though obscurely. The wound is now to be cleansed with a sponge wrung out of water, any spurting vessels twisted or tied, and the edges firmly held asunder with hooks.

2. The next step is the insulation of the artery. The surgeon confines his manipulations to a spot of the extent of a half inch in the middle of the artery, raises up little by little with forceps the cellular texture, and cuts the shreds clean away, as in the operation of hernia. The arterial sheath being laid bare at this circumscribed spot, is then opened, either with a pointed director, or by taking up a minute fold with forceps and shaving it off horizontally. An aperture is thus formed in the sheath, through which the artery can be detected. The place where the opening is first made is always the most available, and not to be lost sight of by young operators. If the sheath is hard and yellowish, it may be concluded that the artery is diseased and adherent. Here additional foresight is called for, as it becomes requisite to include the sheath in the ligature, after having previously withdrawn any nerves and veins. Into the aperture of the sheath a director is to be passed up and down, the former freely divided along the groove to the extent of a couple of inches, so as to give plenty of room for further manipulation. The artery is next insulated, that is, detached from nerve and vein, by means of a small blunt hook introduced within the slit sheath. It is afterwards loosened from its bed, so as to allow adequate space for the application of the ligature. The gentle drawing forward of the artery with a blunt hook protects the surgeon against the risk of tying nerves, and other vessels, because they are brought into view. Immoderate denudation of an arterial trunk is prone to be followed by gangrene of the vessels, and death from secondary hæmorrhage. The artery having been duly insulated, the next step is the application of the

3. Ligature. This is effected by conveying an aneurism needle armed with a fine waxed silken thread underneath and around the vessel, which is next unthreaded and withdrawn. A double knot is made, one end of the thread cut off close to the knot, and the long end drawn out of the wound and bound to the skin with an adhesive strip. The lips of the wound, after all bleeding has ceased, are to be carefully united by means of sutures and plaster.

There are some things that may require to be considered, either during or after the operation. Ulcers of the integument and large varicos have occasionally, in the instances of the crural artery, obliged me to make the incision at a distance, and to apply the ligature in a roundabout way. The bleeding during the operation is not in general copious; it is nevertheless sometimes parenchymatous. If divided muscular branches jet, they are to be twisted or tied. Should the thread cut through the artery, and hæmorrhage ensue, an accident which can happen only when the former is violently strained, or the latter in a morbid state, a stronger ligature must be applied with moderate firmness both above and below the breach of continuity.

After the operation, the limb is to be placed so as to relax the muscles. The limb is generally rather colder than natural, and the patient experiences a sense of creeping, and as if the part were asleep or numb. In the course of a few days, when the collateral circulation is fully established, the extremity feels many degrees warmer, the patient finds it often preternaturally cool, sometimes hot, and complains for the most part of burning heat and of nervous twinges resembling electric shocks. Loosely enveloping the limb in flannel or cotton wool is the appropriate covering. The diet and regimen during the early days ought to be mild, nutritious, and cooling, so as to allay the disturbance in the circulation; afterwards more stimulating sustenance may be allowed.

The sutures may be taken out upon the fourth or fifth day, but the strips of plaster left until the wound is healed. After the lapse of seven or eight days, a gentle pull may be given to the ligature and when it is brought away, strips of plaster are to be placed over the orifice. If the wound is united at the base, but discharging pus from the surface, layer of soft lint may be laid under the strips, and the lips somewhat approximated. If, on the other hand, the skin is adherent, and matte collected beneath, the edges of the wound are to be parted, the pus evacuated, and the cavity stuffed with lint; if, again, one portion is healed while another is suppurating, the former is to be shielded with strips of plaster, and the latter filled with soft lint.

Secondary bleeding at an advanced period demands immediate ligation of the vessel at a sound pot above the site of the operation. It would be vain to think of tying the artery at the original place, because the parts are so altered by inflammation and suppuration as to defy all attempts at nsulation.

Frequently the condition of the limbs oscillates, for days and weeks after the operation, between life and death. Sometimes it is of a cadaverous paleness; sometimes there are marks of venous congestion in the skin, denoted by small and large blue dots. Warm aromatic poultices serve to restore the flagging circulation. Should there be no signs of returning vitality, frictions are to be employed, with warm aromatic cataplasms; the limb is to be put in a loping position, arnica and phosphoric acid being administered internally. Despite of all remedial means, sphacelus occasionally follows, and assails either solitary portions of the skin, the fingers, and toes, or extends to the large joints, which assume a leaden hue. Here the stimulant treatment is indispensable. The surgeon meanwhile waits till there is a line of separation between the dead and living textures, and resorts to amputation, provided the patient has sufficient strength for recovery. To have recourse to this extreme measure during the progress of gangrene, is against all modern experience and precept. Gangrene of the wound would betoken the last degree of prostration of the vital powers. It has never come within the scope of my observation.

OF THE THREADS AND NEEDLES USED IN TYING THE MAIN ARTERIES.

The most eminent surgeons concur as to the propriety of employing fine ligatures. The broad ligatures of Paré, Heister, Scarpa, and others, with and without interposed cylinders, have not afforded favourable results. The same may be affirmed of the so-called soluble ligatures composed of skin, catgut, silkworm gut, and the like. They act severally as extraneous bodies, swell up, cause purulent deposits, and counteract or retard the cure.

The application of two ligatures, of which the lower one is secured with a knot, while the upper is left loose, to be tied in the event of hæmorrhage (Cline, Birch,) is detrimental, and obstructs the healing process; should the former determine secondary bleeding, the latter would, in all probability, cause it likewise. The applying two tight ligatures, and cutting through the artery in the interspace, to obviate tension, is a futile and hazardous proceeding. The opposite plan of noosing the artery with threads as a preventive of division or of secondary hæmorrhage, to be removed after a while, instead of lightening renders the sequel of the operation more perilous. The line at which the annular compressure is made is prone to rupture; and, as no regular thrombus can form, after-bleeding or non-obliteration is likely to accrue from the manœuvre.

A great variety of aneurism needles have been invented with the view of lessening the difficulties of operating. There is no more convenient instrument, however, for general use than the common hook-shaped needle with a blunt point, and an eye of moderate size. For deep-seated arteries, Desault's needle, as improved by Langenbeck, (or as modified by Weiss,) may be employed. A spring with a hook projects from the curved part, to which the thread hangs, and enables it to be insinuated round the vessel.

The Public Health during the Last Week —It is highly gratifying to learn that the mortality from cholera in the provinces is steadily diminishing, while in London a most important decrease has occurred.

Microscopic Demonstrations.—The annual course of demonstrations will commence on the 24th inst., in the Theatre of the Royal College of Surgeons, by Mr. Quekett, the conservator of the Museum. Members only have the privilege of attending these valuable demonstrations.

REVIEWS.

Report on the Chemical Pathology of the Malignant Cholera, containing Analyses of Blood, Dejections, &c., of Patients labouring under that Disease in Newcastle and London, &c., &c. By W. B. O'Shaughnessy, M.D., &c., &c. Published by Authority of the Central Board of Health. London: Highley. 1832.

On the Intestinal Discharges in Cholera. By E. A. Parkes, M.D., Assistant-Physician to University College Hospital. "London Journal of Medicine," February, 1849.

On the Pathological Condition of the Blood in Cholera. By A. B. Garrod, M.D., Assistant Physician to University College Hospital. 1849. "London Journal of Medicine," May, 1849.

Dr. O'Shaughnessy's report, published in 1832, was a most important contribution to our knowledge of the changes induced by developed cholera in the composition of the blood; and although more recent observers have not confirmed the accuracy of his experiments in all particulars, yet, in the main, the results obtained have stood the test of the present epidemic. The fact, that the *à priori* indications for treatment which he deduced have been impeached, also *à priori*, by one of the most recent riters on the Chemical Pathology of Cholera, as well as the intrinsic value of the report itself, lead us to bring a pamphlet of so old a date under the notice of our readers.

Dr. O'Shaughnessy's report was published by the authority of the then Board of Health. He takes for his standard of healthy blood Lecanu's Analysis, hen but recently published.

The functions of the saline materials of the blood were at that time, as they still are, but imperfectly understood. Dr. O'Shaughnessy says,—

"The attempt to demonstrate the uses o the saline ingredients of the blood, is a circumstance of very recent occurrence, and almost exclusively attributable to the extraordinary clinical statements of Dr. Stevens, of Santa Cruz, whose experiments have riveted the attention of all the scientific physiologists and practitioners of Europe and America, and the probable importance of which may be estimated from the fact of their having been characterised by Dr. Prout, as apparently unfolding 'the germs of immense benefit to mankind.'"

And he concludes that the absence, or diminished *proportion* of the saline matters of the blood, is connected, in some unknown manner, with the production of various diseased conditions.

The following is a comparative view given by this Author of the chemical composition of the serum of healthy blood, Cholera blood, and blood taken from a person suffering from bilious diarrhœa:—

	Health.	Malignant cholera.	Bilious diarrhœa.
Water ..	906·00	854·00	921·75
Albumen	78·00	133·00	61 85
Sol. salts	8·10	4·00	7·30

Further on, Dr. O'Shaughnessy says—

"The summary of my experiments may, therefore, be described as denoting a great but variable deficiency of water in the blood in four malignant cholera cases—a total absence of carbonate of soda in two—its occurrence in an almost infinitessimally small proportion in one—and a remarkable diminution of the other saline ingredients."

The therapeutic indications deduced from the consideration of the chemical constitution of cholera blood by Dr. O'Shaughnessy were—

First, to restore the blood to its natural specific gravity.

Second, to restore its deficient saline matters.

"With respect to the treatment of the fever stage, I would expect much benefit," he adds, "from the frequently repeated use of the neutral salts by the mouth or by enemata, and dissolved in large quantities of tepid water."

Our readers will remember, that it was this treat-

ment which Dr. Stevens asserts he found practically so useful in treatment of Cholera in the Coldbath-fields prison and elsewhere during the epidemic of 1832.

Dr. Parkes, after detailing the particulars of thirteen analyses of the stools, passed by patients affected with cholera, at different periods of the disease, informs us, that his observations agree with those of O'Shaughnessy, Vogel, Wittstock, Buchanan, and others, made during the previous epidemic. He draws from his analyses the following, among other inferences :—

The fluid passed per anum is derived from the serum of the blood, but is not composed of all its ingredients ; it consists of its water and of its salts, with a very small proportion of its organic elements.

The Cholera fluid, in its purest form, consists of little else than water, salts, and coagulable organic matter, which is probably albumen.

The salts and the albumen do not vary much as to quantity or nature, at the different periods of the disease.

That the total quantity of soluble salts thus drained off from the blood must, in some cases, have been considerable, there can be no doubt, when it is observed that they constituted from 6 to 11 parts in 1000 of each stool examined by Dr. Parkes ; the amount of albumen in three only of nine cases reached the proportion 1 in 1000 parts; the proportion of water varied from 972·82 to 999·053.

When we consider, therefore, the immense quantity of fluid passed from the alimentary canal, and remember that no absorption is going on, according to the most generally received opinion, the conclusion seems inevitable, that there must occur, after a short time, an alteration in the chemical composition of the blood. Knowing, therefore, what the constitution of any given individual's blood was prior to the attack, and the quantity and chemical composition of the ejected and dejected matters, we ought to be able to determine what must be, or nearly so, the chemical constitution of the blood in the same individual after any given period of purging. The results of the experiments of Dr. O'Shaughnessy are in accordance with those we should have supposed *à priori* would have been obtained,—diminution in the amount of water and salts, and a *relative* increase in the amount of albumen. It is evident, that very little albumen being dejected, while a large amount of water and saline ingredients pass off, the former must increase in proportion to the latter, although considered as a whole, its quantity must have diminished.

Dr. Garrod draws the following conclusions from his analysis of the blood in cholera, made during the present epidemic.

The water is diminished, and the solids increased.

The blood globules are increased in amount.

The serum is considerably altered from its healthy condition. Its water is diminished; its solids increased in quantity. It has a tendency to become less alkaline, and even neutral in its re action.

The albumen in 1000 parts of serum is always increased.

The above conclusions are in accordance with those arrived at by previous observers ; but, with respect to the saline elements of the blood, Dr. Garrod arrives at very different results.

"The saline constituents," says the Author, "are not only not decreased in amount, but sometimes exist in even increased proportion."

Lecanu's analysis of the serum is used by Dr. Garrod, as it was by Dr. O'Shaughnessy, as the standard of comparison. We do not doubt the accuracy of Dr. Garrod's analyses, but they appear to us, contrary to what he seems to think, to bear out the therapeutic indications laid down by Dr. O'Shaughnessy in 1832.

The result of Dr. Garrod's analyses may be expressed, it seems to us, more clearly thus—

The absolute amount of saline ingredients in 1000 parts of the serum of cholera blood, is normal ; considered in reference to the water in 1000 parts of serum, the salts exist in a proportion within the limits of health ; but, viewed in reference to the albumen, they are extremely diminished in quantity. The latter remark applies also to the proportion which exists between the red corpuscles of the blood and its salts ; *i.e.*, relatively considered the salts are diminished in amount.

It may appear the same, to say that the albumen and the red corpuscles are increased, and the quantity of the salts is normal, as that the salts are diminished and the blood corpuscles and albumen are normal in quantity. But, therapeutically, the two things are very different, for any attempt to remove the supposed excess of blood corpuscles and albumen, would be to endeavour to substitute true hæmorrhage for the loss the system has sustained by the serous diarrhœa ; while the consequence of adding salines and water, and by that means restoring the relative normal proportion between the blood corpuscles, the albumen, the salts, and the water, would be to bring the patient back *so far as the known chemical constitution* of the blood is concerned, to a state of health.

In order to illustrate our meaning, let us examine one of the cases detailed by Dr. Garrod, viz., that of William Worts, aged 39, a patient admitted into University College Hospital, under the care of Dr. Williams, February 1, 1849. The stools passed by this man were examined by Dr. Parkes, the blood by Dr. Garrod. At the time of admission he was in a state of mild collapse ; he was purged repeatedly during the first hour after he entered the hospital, and then had six stools between 2 p.m. on the 1st, and 2 a.m. on the 2nd, at which time some blood was drawn from his arm.

Three analyses of the stools were made during the time he was under observation. The mean amount of soluble salts found in the stools was 7·46 in 1000 ; of albumen, 2·78 parts only, *i. e.*, the relative proportion between the water and the salts was nearly the same as in the healthy serum of the blood, while the albumen amounted to only 1-27th of that found in the same fluid.

Now the composition of the serum of the blood drawn from the arm of this man was—

Water........	882·9
Albumen	125·40
Soluble Salts..	8·12

So that the amount of albumen in this blood was, when compared with the healthy standard of Lecanu, vastly increased, in fact, nearly doubled, the quantity of the salts in 1000 parts calculated absolutely, was exactly as much as it would have been in the same man in health,—while the water had somewhat diminished. It is evident, then, that the apparent increase in the amount of the albumen was dependent on loss of water and salines ; and, in order to have brought that serum to the condition of health, we must have more than doubled the quantity of water it contained, and exactly have doubled the saline elements.

The blood corpuscles were found to be relatively increased,—they were in the proportion of 166 instead of 141·1 in 1000 parts ; but as extreme practical difficulties exist in determining their precise amount in any given quantity of blood, all that we can correctly say is, that they were considerably increased in quantity. According to the most recent opinions of Physiologists, it is on the blood discs and the albumen that the saline ingredients exert their chief physiological influence, whatever that may be. Now the relative proportions of these elements were changed, and, as a necessary consequence, the action of the saline constituents on the organic elements of the blood must have deviated materially from that which they exert in a state of health. For all practical purposes, then, in spite of Dr. Garrod's—in a *certain sense* correct—statement, that "the saline constituents of the blood are not decreased in cholera," Dr. O'Shaughnessy was right when he stated, that so far as chemical analyses could afford indications for treatment, those indications were, to restore the blood to its natural specific gravity, and to restore its deficient salts. Dr. Stevens asserts, that practically he has proved that the administration of salines did restore to health an immense per centage of those he treated ; and it appears to us that with such theoretical and practical testimony in their favour they deserve a more extended trial than they have yet received. As to the *à priori* reasoning against the employment of salines in the treatment of cholera, founded on the fact, that cases of that disease prove rapidly fatal, where no vomiting or purging, and, consequently, no loss of saline ingredients, has taken place, this answer founded on analogy may be given : in small-pox, death may ensue from the action of the poison before the eruption appears, or it may result from the constitution of the patient being unable to support the immense drain caused by the sudden formation of so much purulent matter on the surface, *i. e.*, the patient may die from the direct action of the poison, or from secondary disease—the consequence—and, if death do not ensue at an early date, the invariable consequence—of the imbibition of the poison into the system. Is it not probable, then, that the same may hold true with respect to cholera ? Thus far we have written, as if *à priori* reasoning was of some value in determining the question of the best method of treating cholera. This, however, is as far from our meaning as it is from the truth. The indications deduced from Chemical Pathology are only of value as suggesting a mode of treatment to be fairly tested by experience. To that all must bow. Would that the therapeutic efforts of Practitioners of Medicine in the present epidemic had been so systematically conducted, that, by an analysis of their experience, trustworthy, indisputable results might have been induced.

REPORTS OF SOCIETIES.

MEDICAL SOCIETY OF LONDON.—Sept. 24.

F. Hird, Esq., President.

LEMON-JUICE IN RHEUMATISM.

Dr. Thompson referred to a discussion which had taken place at the last meeting of the Society, on the use of lemon-juice in cases of rheumatism, stating, that a patient upon whom he had just called had been treated with that remedy ; and he mentioned it, because it bore on the question, whether the action of lemon-juice depended on its possessing qualities similar to other remedies. It had been said, that lemon-juice and acetate of potash acted in the same way, and were, in fact, almost equivalent remedies. Now, in the case he alluded to, it was one of rheumatic pericarditis, leading to effusion into the pericardium. The patient had been treated by a free use of acetate of potash, but this did not prevent severe rheumatic pains, especially about the knees. The heart symptoms were relieved, but the urine deposited immense quantities of lithates. He gave up the potash and employed lemon juice. The patient

having taken in all four lemons, the condition of the urine was materially altered, and the pain of the rheumatism thoroughly subdued; while the change effected in the urine was very different to that produced under the use of acetate of potash. Thus he thought the powers of lemon-juice had been fully established, though the mode in which it acted had not yet been explained.

Mr. Clarke: Does Dr. Thompson mean that rheumatic pericarditis was the original disease, and that acetate of potash was given for that?

Dr. Thompson: There had been pericarditis, but he could not say that there had been rheumatic pericarditis, though he thought there had. The patient under the acetate of potash receives no relief; he changes it for lemon juice, and there is a thorough subsidence of the rheumatic pain and other symptoms.

Dr. Copland: How did the heart disease fare afterwards?

Dr. Thompson: The heart appeared perfectly sound. My opinion is, that inflammation of the pericardium led to effusion of serum, but not to effusion of lymph. The acetate of potash was given after there was reason to think there was effusion into the pericardium. It failed; and, therefore, lemon-juice was employed. The patient was suffering materially from the middle of last week to its end; the lemon-juice was given on the Thursday, and discontinued to-day; the quantity was a table-spoonful every four hours up to Friday, Saturday every six hours, and yesterday twice only. To-day he is free from the use of it.

Dr. Crisp: I am sure Dr. Thompson is too experienced in the fallacy of drawing conclusions from one or two facts, and, therefore, I should think he does not attach much importance to this case. I had the pleasure of hearing Dr. Thompson before on this point, and there it was doubtful whether it was a case of rheumatism at all. But I would especially caution the Society from drawing inferences from isolated facts, and I rise to ask D Thompson whether, if he were called to a case of rheumatism, and he apprehended metastasis to the heart, whether he would trust to lemon-juice alone or whether only he would use it cautiously in cases where there was no danger of heart affection.

Dr. Thompson: Dr. Crisp has really expressed my motive in adducing the case. When I first brought it forward, I referred to several cases, but particularly described one, and my reason was this, —that I feel the great necessity of caution being observed, and of ascertaining the mode of action of lemon juice; and here it appears to me that this case is of value as bearing on the question. I confess, that if the pericardium was affected, I should be afraid at present of trusting to lemon-juice; but I should use it where one is afraid of bad effects from more active remedies.

Mr. Clarke: The view of Dr. Bird was, that lemon-juice increased the specific gravity of the urine, and it was from a great number of cases that he drew this inference, while Dr. Thompson's was only a solitary one.

Dr. Thompson: I did not recollect that Dr. Bird took his views from a great number; I think that number was small; and as it respects the specific gravity of the urine, though I believe the increase in the solid contents of the urine is a common thing, yet here we have exceptions. I have known cases where there has been no increase of the specific gravity. Here, again, we must pause before we form conclusions; a little light has been struck, but the subject is not yet fully illuminated.

The President observed, that Dr. Bird had not tried lemon-juice very extensively.

Mr. Harvey then read a paper on

RHEUMATIC DISEASE OF THE EAR.

His attention was first directed to the subject, by observing the effect of rheumatic inflammation on the tissue of the eye, and from noticing, in many cases of ear disease that came under his care, the presence of articular rheumatism, which, influenced either directly or indirectly, the ear disease, the relief of one, for instance, being followed immediately by aggravation of the other, &c. Believing, from observation, that many such cases were made worse, and even irremediable, by mistaking the cause of the disease, and by the application of stimulating remedies, he determined on investigating the subject. The result has been, that in a great number of cases he has been able to trace the connexion of the ear affection with rheumatism of the system generally. In the eye, the secondary attack has been usually found to come on after the system has been well saturated by the poison of the disease; but the ear may become affected early, the parts first implicated, as in the eye, being the fibrous tissues, and, subsequently, the nervous expansions. The disease exhibited itself under two forms—the acute or destructive, and the chronic or insidious; both, when neglected, tended to impair the sense of hearing; and the former, to the entire destruction of the organ. The acute form generally attacked males, and was connected with articular rheumatism; the chronic was more frequent in females, and was associated with rheumatism of the muscular system. The symptoms of the acute form of the disease, to which the paper was restricted, are, that the attacks are paroxysmal usually following a seizure of articular rheumatism tinnitus aurium, resembling the pumping of a steam engine or forge-bellows, and generally a benumbed sensation over the temporal and mastoid regions. This was the part chiefly implicated in the disease which, if not speedily relieved, ended in the exfoliation of the bone. Some cases were detailed by Mr. Harvey; in one, the patient was a strong robust man, in whom the attack supervened on a severe rheumatic affection of the joint, which had been treated actively. On the entire subsidence of the joint-affection, the left ear became the subject of severe pain, there was a benumbed sensation over the temporal and mastoid processes, accompanied with a heavy deep tinnitus. There was considerable tenderness over that portion of head. The meatus was much swollen, in consequence of the application of hot and stimulating remedies. He had difficulty in swallowing; the l tonsil was much enlarged. He was cupped a leeched over the mastoid process, and placed under the influence of mercury with colchicum. This was pursued for ten days: the tympanum could now be seen: it was of a brownish-red colour, and had l its transparency. The pain had diminished in intensity, but the tinnitus continued: he had occasional flying pains about the joints. Pain and tenderness continued over the mastoid process, and though no fluctuation could be detected, an incision was made over the part down to the bone. Relief followed; he slept better. Colchicum, with quinine, was given, and the patient recovered, though for twelve months his hearing was somewhat affected. The second case was of a similar character, but owing to the obstinacy of the patient, a female, who refused to allow of any incision being made over the mastoid process, th structure of the ear was destroyed, and the bone exfoliated, notwithstanding active and judicious means were used to prevent it. The third case was one associated with cardiac inflammation, which ended fatally; the ear disease, under the treatment pursued in the first case, was but little benefited. In concluding his paper, the Author lays great stress on the necessity of the incision over the seat of pain, and considers, that in the second case, that proceeding, if adopted, would have been as beneficial as in the first. In some remarks on colchicum he says—

It appears to me that colchicum may act chemically by producing some change in the urinary and alvine secretions, both of which it tends to increase in quantity and alter in quality; and, secondly, it acts particularly upon the nervous system. If given in large doses, it should be carefully watched as to its effects. It should not be given in a weakened constitution without either a tonic or an opiate, and it is better to have the bowels freely acted upon at first. I have found it extremely beneficial to continue its use internally for a lengthened period, in small and repeated doses, in chronic affections of the ear presumed to have arisen from rheumatism. I have found it by no means beneficial when it produces nausea, vomiting, or purging, and more particularly beneficial when the skin secretes freely: the preparations I place most reliance upon are the wine of the seeds internally, and the acetous extract, combined with spermaceti, as an external application. He usually adminstered the colchicum wine in small doses, such as five or six drops at first, in chronic cases, continuing the remedy for a long period. He conjoined it with a bitter infusion. In acute cases he gave half a grain of the acetous extract with two grains of calomel, three times a day, till ptyalism was produced.

The President inquired of Mr Harvey, whether he had ever tried lemon-juice?

Mr. Harvey: I have not thought much of lemon-juice; the colchicum, to my view of the matter, in metastatic affections of the ear, has been quite efficacious. I have tried iodide of potassium, but usually relied on colchicum. I never give any heroic dose of the wine of colchicum, thinking it better to carry on the treatment for a considerable time; I therefore confined the dose to five or six grains. In chronic cases I gave mercury, with a view to salivation, and colchicum as a known specific. In twenty-four hours I gave the acetous extract three times.

Dr. Crisp: Are the incisions made deep or superficial?

Mr. Harvey: Deep; through the bone.

Dr. Crisp: I have seen the disorganizations from inflammatory action during scarlatina; and I apprehend that colchicum would be equally efficient after scarlatina. But, as it regards the action of colchicum, I think the Profession has yet the lesson to learn as to the ultimate effect of particular medicines, on the duration of life. It is a subject of great importance; and I make this observation now in consequence of a remark made by Dr. Stokes in Dublin, that "he had never heard of persons who had taken much colchicum living to a great age."

Dr. Copland: Mr. Harvey has fully proved his case as to rheumatic affections of the ear. But I think I could bring a larger number of cases in which the ear was affected contemporaneously with the face and head. One individual I was acquainted with had several attacks of rheumatism on the left side of the face, but never any pain in the ear, until, going down the river one night, violent rheumatism set in in the face and head, and in that case the ear was severely attacked. That case was not treated by colchicum, but principally by iodide of potassium and sarsaparilla. But in two or three chronic cases which have come under my notice, in which there have been repeated attacks of affection of the ear, there has at last supervened very serious deafness, and there the rheumatic affection of the limbs has been more diminished. I have had great experience in colchicum, having given it in small doses, and it has produced in the robust the greatest depression. I consider Mr. Harvey's opinion most judicious, that colchicum should not be given till the morbid secretions had been evacuated, and not then, unless conjoined with ammonia, or, still more judiciously, with quinine. The prolonged use of it is either productive of shortened life or of amentia.

Dr. Thompson: I cannot refrain from referring to the observation of Dr. Crisp as to the great importance of considering the ulterior effects of of medicines. We are in danger of forgetting that an influence for evil may remain. It may often happen, that the doses which will have the best immediate effect are just the doses which we ought not to give; and it is one of the most important arts in medicine to remove disease, with the least possible expenditure of means. Still, I believe that small doses of colchicum are often appropriate and beneficial.

Mr. Hunt: A subject has been broached to-night, which is new to me—whether the administration of particular remedies has a tendency to shorten life. I am not disposed to dispute it, but I should like to hear the evidence on which such an opinion can possibly be founded. The statistical facts necessary to bear it out must be of such a lengthened nature, and spread over so long a period, together with the peculiarities of constitutions, and various other considerations, being so difficult of acquiring a knowledge of, that I think such an opinion must have been hastily formed.

Mr. Roberts: The impression on my mind is against the idea of colchicum generally shortening life. For the last twenty-five years I have given it to patients suffering from gout, and they are now alive; and I have known persons of advanced age who had taken it for a long period. It requires watching, certainly; but in judicious hands, and well watched, I do not believe colchicum will ever diminish life.

OCTOBER 1.

HENRY HANCOCK, Esq., President.

Dr. Willshire: Before the regular business proceeds, I will first refer to the following circumstance. The other day, I called on a gentleman whom I had attended for inflammation of the intestines. He had been the subject of ascarides all his life, and had tried all sorts of remedies, and when anything is prescribed for him professionally, he refuses it. The last time I saw him, he was suffering much from irritation of the rectum, and he was ordered a lotion of nitrate of silver, from which he received benefit; at the same time, the ascarides had not appeared, but he was much alarmed at finding maggots—(exhibited)—making their escape from the abdomen. His chemist had retained these for me, and when I got them, finding they were something out of the way, I told him not to be alarmed, but to reason well on the matter before he made up his mind as to the circumstance. I took the creatures home, and was satisfied that they were not Entozoa, but simply maggots. Professor Owen told me that they were the larvæ of a dipterous insect, in all probability the musca. Dr. Elliotson gives a case in which a child passed the dead larvæ of the fly,—where a high pheasant had been partaken of. In the present case the patient had eat of a partridge, but the servant told me it was not high. I stated to him, that even if there were more, they could not by any possibility propagate; but he was greatly alarmed, thinking that these creatures had made their appearance in the place of the ascarides.

Dr. Crisp: Six or eight weeks ago, Mr. Skegg gave me a number of larvæ supposed to be of the ichneumon, which had escaped from the bowels of a porter. I imagine these are swallowed. They might pass through the alimentary canal, and be buried alive, but generally they are dead. There are other cases of maggots being in the meatus auditorius; but I do not think the larvæ could live in the intestines.

In answer to a question from the President, Dr. Willshire said, he had not traced any connexion between the high partridge and the larvæ. The question Professor Owen put to him was, whether they were passed by the urethra or per anum.

Mr. Hunt read a paper on

A PECULIAR TENDENCY TO HÆMORRHAGE IN CERTAIN INDIVIDUALS, AND ITS PREDISPOSING CAUSES.

The author restricted his observations to those hæmorrhages which appeared to depend more upon the state of the circulation than of the blood; and related cases illustrative of four different conditions of the circulation, which became so many predisposing causes of hæmorrhage; viz., deficient contractility, increased momentum, nervous exhaustion, and local heat.

The object of the paper was practical, and it was the Author's aim to shew, that these various and opposite causes of hæmorrhage ought to be well considered in deciding upon the treatment. In the case of deficient contractility which was observable in some individuals, who would bleed for hours from a slight punctured wound, or even a scratch, and in whom it was dangerous to apply leeches, mechanical pressure, where it could be applied, was recommended as the only remedy to be relied on. In the case of increased momentum of the circulation in connexion with general plethora, in which the hæmorrhage generally stopped spontaneously, after perhaps a frightful loss of blood, it was shown to be highly necessary, especially in cases of pregnancy, (as recommended by the late Dr. Gooch,) to prevent the occurrence of the hæmorrhage by timely depletion and low diet. In the third case, in which, after delivery, or consequent on the shock of severe accidents or operations, the motor power of the nerves becomes paralyzed, and want of contraction occurs, not as an idiosyncratic affection, but as a temporary deficiency, the sudden application of extreme cold, or irrigating the uterus by a stream of cold water, was proposed as the best practice. The same practice, varied according to circumstances, was recommended in the fourth kind of hæmorrhage, viz., that accompanied by local heat. The sensation of distressing heat, not attended with inflammation, was shown by cases to be a not infrequent cause of hæmorrhage from various organs. The author acknowledged himself unable to explain the *rationale* of this occurrence. In one of these cases a woman was attacked, some hours after a natural labour, with a most alarming flooding, and complained of an intolerable sensation of heat in the uterus. Jugs of cold water poured upon the abdomen failed to relieve the sensation, which was at length subdued, and the hæmorrhage arrested by a stream of cold water injected into the uterine cavity.

The President: There is one point which the Author has not noticed in his paper, viz., the symptoms which would lead the practitioner to diagnose between the four cases he has given.

Mr. Hunt: I considered that the symptoms in all the cases were so obvious, that this was not necessary. Whenever hæmorrhage occurs from a trifling cause, we may infer the first condition of things; on the other hand, when we have a full pulse, we may infer fullness of the system, and so on. There is a degree of local heat occurring in some parts giving rise to hæmorrhage, which generally appears to be the result of some exciting causes, after excesses or otherwise.

Dr. Willshire: It appears to me, that a somewhat deeper analysis would have done away with the causes alleged in Mr. Hunt's paper, and led to the attributing of more general ones. I can never assume local heat as a cause of hæmorrhage, though I may take it to be an accompaniment of stasis of the blood. Accompanying that local stasis we have diminished momentum. Here the development of heat is a mere coincidental affection. If increased momentum exist, it can only be in the heart, not in the vessels; the blood does not move quicker in an inflamed part. I think that only two great causes exist, the want of contractility, and the condition of increased action in the central organ; and so we have increased heat, with a peculiar abnormal condition of the coats of the vessels.

Dr. Crisp: I do not agree with Dr. Willshire that there is not increased momentum in an inflamed part; but I rose chiefly to mention an omission of Mr. Hunt's. He said nothing about the condition of the blood, while it is very questionable whether that condition may not be the sole cause of hæmorrhage. Lemonade has been given in hæmorrhages, and it is worthy of attention, whether in typhus fever a large quantity of lemon-juice might not be more efficient than other remedies.

Mr. Clarke: I must differ with Dr. Crisp as to the condition of the blood being the chief cause of hæmorrhage. In the cases I have observed of this remarkable idiosyncrasy, that question was a good deal set at rest in University College Hospital. In a case of Liston's, in which amputation followed amputation, and the young man sunk under the hæmorrhages, the tendency was hereditary; and I should like to know whether Mr. Hunt has noticed cases of this kind.

The President: The subject seems to divide itself into three classes:—1. Hæmorrhage arising from wounds; 2. from parturition; 3. spontaneous, from unbroken surfaces. In scurvy it looks as if hæmorrhage arose from a want of fibrine in the blood, as pointed out by Milne Edwards, in consequence of innutrition, the blood passing through the coats of the vessels. Then Thackeray's observations went to prove that it was the result of increased momentum. I have seen such patients die from small wounds, and also from the accidental circumstance of a vessel being confined in a boney tube; this is very frequently the result of hæmorrhages which take place in tooth drawing, until by a probe you break down the sides. There is one point in which I differ from Dr. Crisp, as to the increased action in an inflamed part. I have found that, as inflammation goes on, the circulation in that part becomes dilated, but the action of the vessels is slower.

Dr. Willshire: We should be cautious in admitting inferences so long as chemistry can give us no better clue to the condition of the blood. Although the fact should hold good as to the probability of peculiar conditions producing hæmorrhage, yet they do not always produce it. In scurvy, hæmorrhage takes place from a want of cohesion in the soft parts surrounding the seat of inflammation, and therefore there is a peculiar condition of that circulating fluid; but it is the want of cohesion which is rather the cause of hæmorrhage.

Some discussion then ensued as to any hereditary tendency to hæmorrhage, and several instances were adduced bearing on the affirmative view of this subject.

Mr. Hunt: As some have considered that my paper was defective, as it regards the condition of the blood, I will just say, in conclusion, that my intention was not to include these cases. The condition of the blood, as a cause of hæmorrhage, is a subject of itself highly important; but my object was, to bring some practical observations before the Society as to the mode of treating hæmorrhages which have four different, tangible characters. As to the sensation of heat, I used the term meaning a sense of caloric, and not as meaning caloric itself, and mentioned it merely as a practical fact, in which hæmorrhage was best stayed by cold applications, these having the greatest power over the capillaries.

LETTER FROM DR. ARNOTT ON THE USE OF BENUMBING COLD.

[To the Editor of the Medical Times.]

SIR,—I beg to express my sense of your justice in printing the reply to the article respecting me in the *Medical Times* of th 8th ult.; and I earnestly hope that you will grant me the further opportunity of defending myself from the extended criticism in the Number for the present week, and of pointing out some very considerable errors in the statements and reasonings which it contains. Being, however, at present, in the enjoyment of a short "physician's holiday," I am not only little indisposed to mingle its sweets with the bitter, but I am unprovided with the documents necessary to be referred to, and must, consequently, beg the indulgence of another week for my reply, trusting that those interested in the point will, until then, suspend their judgment.

At the same time, I am anxious that the valuable antiphlogistic and anodyne remedy which I have recommended should not suffer in reputation by my delay in answering the new objection, that its value has not been confirmed by the testimonials of other practitioners. For this reason, I subjoin an extract from a letter on the subject, received just before I left home, and which I have fortunately brought with me; and, although I do not conceive that I am obliged, for the reasons mentioned in the *Medical Times*, to confirm my own statements by the reports of others, seeing, among other reasons, that every one who doubts my evidence has it in his power to ascertain the truth himself by the simple expedient mentioned in my last communication, I readily grant that any prejudice against the therapeutic agent which I recommend, arising from its having only been hitherto known as a cause of disease, will be more quickly so removed. The letter is from a very eminent physician, acknowledged by every one who has read his lectures on "Clinical Medicine" to be inferior to no authority in the Kingdom on any subject connected with practical medicine. I have not the honour of being personally acquainted with Dr. Graves, and it is with great reluctance that I publish his sentiments without his expressed consent; but I feel convinced that his desire to protect what is really useful in the healing art will induce him to pardon the liberty I take, under the peculiar circumstances which I have mentioned.

"I have twice (he says) advised the use of benumbing cold according to your method, and with such success as to lead me to consider your discovery as one of the greatest practical importance."

This passage refers, of course, to the general use of extreme or benumbing cold. As to its employment in cholera, which is especially, but not exclusively, attacked in the *Medical Times*, I am only at present desirous to add, that its advantage consists in its fulfilling the indications which those who have exhibited ice in cholera have so often failed in fulfilling, from a deficiency in power in the means that they have used. Nevertheless, the ice practice, has, I find, been in high estimation in the city where I am now residing; and some of the late English medical journals show that it is gaining a similar reputation in England.

I am, Sir, your most obedient servant,

JAMES ARNOTT.

Paris, Oct. 7th, 1849.

We publish the above letter, and will find a place for Dr. Arnott's promised communication. For ourselves, we have said our say, and that the more decidedly, from knowing, in the first place, the influence of the name of Arnott; and, in the second, that few men take the trouble to think for them-

selves. As *we* shall not return to the subject, we would observe, that for Dr. Arnott we have the highest respect; nay, more, we have personal regard. His opinions, however, are public property, and, as public Journalists, it is our duty to discuss them.—Ed. *Med. Times.*

MEDICAL NEWS.

Apothecaries' Hall.—Names of gentlemen who passed their Examination in the science and practice of medicine, and received certificates to practise, on Thursday, Oct. 4, 1849:—Joseph Skelding, Bridgnorth; Robert Hamilton, Ipswich; George Paton, Wetherby; John Anderson, London; William Robert Stewart, London; Clement Madely Smith, Horncastle.

Royal College of Surgeons.—The following gentlemen having undergone the necessary examinations for the diploma, were admitted members of the College at the meeting of the Court of Examiners on the 5th inst., being the first meeting this session:—Messrs. George John Hinnell, Tamworth; Henry Merrill Williamson, Chapel-en-le-Frith, Derbyshire; Richard Skinner Henning, East Brent, Somersetshire; John King Maconchy, Dublin; Henry Tregelles Fox, Dunmow, Essex; John Strean Armstrong, Belfast; James Denholm Pridie, Stockton-on-Tees, Durham; John Horsley White, Wolverhampton, Staffordshire; Charles Nathaniel M'Caull, Dublin; William Henry Tinney, Ottery St. Mary, Devon; and William Cowen, Stokestown, county of Roscommon.

Obituary.—At the residence of Mr. Edge, surgeon, Salford, after seven hours' illness, Mr. John Williams, M.R.C.S. and L.A.S., a victim to his assiduous efforts to relieve the cholera patients placed under his charge—On Wednesday, the 3rd instant, at his house, No. 5, Carlton-terrace, Brixton, Surrey, after a very short illness, James Crawford Ferrier, Esq., M.D., in his 41st year—On the 6th instant, at Brighton, John Taylor Warren, Esq., Inspector of Military Hospitals, much esteemed and lamented, aged 78.

MORTALITY TABLE,

(Metropolis.)

For the Week ending Saturday, Oct. 6, 1849.

Causes of Death.	Total	Average of Five Autumns.
All Causes	1290	1162
Specified Causes	1284	1158
Zymotic (or Epidemic, Endemic, and Contagious) Diseases		
Sporadic Diseases:		
Dropsy, Cancer and other Diseases of uncertain or variable seat	44	49
Tubercular Diseases	110	178
Diseases of the brain, Spinal Marrow, Nerves, and Senses	101	125
Diseases of the Heart and Blood vessels	23	40
Diseases of the Lungs, and of the other Organs of Respiration	123	214
Diseases of the Stomach, Liver, and other Organs of Digestion	76	65
Diseases of the Kidneys, &c.	9	11
Childbirth, Diseases of the Uterus, &c.	6	10
Rheumatism, Diseases of the Bones, Joints, &c.	12	8
Diseases of the Skin, Cellular Tissue, &c.	3	1
Malformations	5	4
Premature Birth and Debility	24	23
Atrophy	37	18
Age	48	57
Sudden	5	12
Violence, Privation, Cold, and Intemperance	22	36
Causes not Specified	6	4

The following is the number of Deaths occurring from some of the more important special causes:—

Apoplexy	20	Heart	18	Phthisis	92
Bronchitis ...	37	Hooping cough	27	Pneumonia ...	71
Cholera.........	288	Hydrocephalus	20	Scarlatina	39

TO CORRESPONDENTS.

Cholera Table Returns."—We have received several of our Cholera-tables; and have to offer our acknowledgments to the gentlemen who have so ably filled them up. We are particularly obliged, in this respect, to Dr. Corfe, of the Middlesex Hospital, to Dr. Aldis, and his pupil, Mr. Vincent Litchfield, of Twickenham, to Dr. Hooper, of Buntingford; Dr. Jones, of Anglesea; Dr. Cheyne, of Berner's-street; Dr. Harcourt, of Chertsey, and others. Some of these reports are so full of matter of deep interest, that we would gladly have published them as we received them, but, upon consideration, it seems more advisable to adhere to our first intention, to analyze the returns as a whole, and lay them before the Profession. Upon this subject, we further beg to state, that Dr. Hilbers, of Liverpool, will, we think, serve the interests of the cause he advocates more effectually by inserting his communication in a Journal devoted to the promulgation of the peculiar views he holds. He misunderstood us, if he supposes that we promised to publish all the Tables we might have returned to our office. What we intend is, after we have collected a sufficient number of cases, treated by different practitioners in different ways, to analyze them, and then to give the results, and such of the particulars as we may think interesting to our readers. We believe the notes of the cases, forwarded by Dr. Hilbers, bear internal evidence of their authenticity and accuracy, and for this reason, that we find, on a careful perusal of them, that little more than 50 per cent. of the cases detailed (*i.e.*, of those among them which *we* should consider cholera) recovered, and such per centage we believe to be about that which even when the disease is severe, the uninterrupted efforts of nature may effect, and certainly far below the success which some advocates of the unadulterated cold-water system assert they have obtained. In support of our statement we may refer to Mr. Ross' Fifth Lecture on Cholera, published in the "Medical Times" of November, 1848. We really hope Dr. Hilbers will publish the *whole* of his cases, in one of the homœopathic journals, in our tabular form, which he has so carefully filled up. We shall be happy to supply him with any number of copies. We think the results deeply interesting, as presenting a natural history of the progress of the disease to recovery or death. Our only objection to publishing the papers *originally* in our Journal is that we should be bound to admit criticisms, &c., on them, and thus our pages would be occupied by an homœopathic controversy, when, in our opinion, they might be more profitably employed. Dr. Hilbers is correct in attributing our delay in noticing his communication to other causes than want of courtesy.

"Dr. Henry McCormac, of Belfast," has, with his valuable Works on "Continued Fever," and the "Modus Medendi," sent us a very useful little pamphlet on the "Management of Cholera in the absence of Medical Advice." The proceeds of its sale are destined for charitable purposes; it is published at a very cheap rate, and we earnestly recommend it to the attention of the charitable for circulation among the poor. "I have been often asked," says Dr. McCormac, "what is to be done in the absence of medical advice, and in case of an attack of cholera?" The following directions are intended as a reply. The position of a person, in the early stage of cholera, resembles that of a wounded man labouring under severe, and, unless arrested, mortal hæmorrhage. The importance of stopping the discharge, and relieving the sufferer, is hardly greater in the one case than in the other. The first and most important requisite, and the second, and the third, is at once to put an end to the discharge. With this there is safety, and more safety, and most safety—and, without it, there is none."

"Dr. Gondret, of Paris."—Both received.

Mr. J. Grantham's Communication has been received.

"Dr. J. W. Boyd, New Ross, Ireland," is thanked for his suggestion, which shall be attended to.

"Medicus, Gainsboro'," asks whether legal proceedings can be instituted against a quack for practising without a diploma, independent of any sanction from, or connexion with, the Apothecaries' Company. Yes.

"Mr. G. C. Kernot, Poplar."—The work will be brought to a close in the present volume.

"Dr. Williamson, Brighton."—A private communication has been sent.

"A Constant Reader and Subscriber" writes, "In last Saturday's 'Medical Times,' in answer to 'Medico-Chirurgus,' you state the sums paid to medical men when called upon by the police to attend persons at the station-house. Does the rate of payment belong to London alone, or to all places indiscriminately? Is the medical man allowed to charge if he is Surgeon to the Union in which the station-house is situated." The rate of payment is not confined to the Metropolis, nor does it affect the validity of the claim by a medical man holding a parochial appointment.

D. Z., Iron Works."—The appointment of Assistant Surgeons of the East India Service is in the patronage of the Directors. A form of certificate, printed for the purpose of the blanks being properly filled up and signed previously to the Assistant-Surgeon being nominated, can be obtained by application at the Cadet Office, East India House. Assistant Surgeons, with these Certificates duly signed by the person who obtained their nomination from a Director, must present themselves, before ten o'clock in the morning, in order that they may have their nominations prepared against either the meeting of the Committee, or the arrival of the Nominating Director.

"Juvenis" wishes to know "whether a surgical diploma is indispensable for candidates for the situation of Assistant-Surgeon in the navy, or of a degree of medicine would be a sufficient qualification for that office." No person will be admitted who cannot produce a certificate or diploma from either of the Royal Colleges of Surgeons of London, Edinburgh, or Dublin. A favourable consideration is given to the cases of those who have obtained the degree of M.D. We would advise our Correspondent not to think of entering the navy at present. The Assistants are still subjected to numerous insults, and it is only by persevering efforts on the part of the Profession that grievances will be removed. Resignations are frequently occurring, and there are at present very few candidates to fill up the vacant places.

"Dr. Bascome's" letter shall appear at an early opportunity.

"Mr. W. Foss, Stockton-on-Tees" informs us, that in a case of cholera which he attended, and in which the patient had cramps, involuntary rice-water evacuations, attended with great prostration, he ordered the extremities to be rubbed with warm flannels, a mustard plaster to be applied to the abdomen, and the following mixture to be taken:—℞ Ant. potass tart., ℈ij; tinct. camph. comp. ʒi.; sp camph., ʒi; aq bullientis ad., ℥viij.; a table spoonful every ten minutes. After the second dose, the patient had profuse perspiration, cramps and purging left her, and health was quickly restored. The antimony did not produce vomiting, but acted as a sedative. In the case of a child, three years old, under the saline treatment, a blue and collapsed state speedily supervened. Tartarized antimony, with the tinct. camph. comp., was then prescribed, which was followed, after the second dose, by a profuse perspiration and calm sleep. This patient afterwards quickly recovered.

"Dr. Richard Sargent, Clonmel."—Received, with thanks.

"A Subscriber" says:—"Not a very long time ago there appeared in the pages of the 'Medical Times,' a form or a history of a bread, well calculated for diabetic patients. I have not time or opportunity just now to look back to the article: can you, or will any of your numerous correspondents, give me the information, accompanied with any pertinent remarks on the diet that has been found most useful for this class of cases?"

"Dr. Hastings."—We had intended to publish a communication by Dr. Hastings on the treatment of Cholera by the bisulphuret of Carbon. A press of matter obliges us, at the eleventh hour, to postpone its appearance until next week.

A CLINICAL LECTURE

ON

CHOLERA.

DELIVERED AT KING'S COLLEGE HOSPITAL, OCTOBER 12, 1849.

By Dr. GEO. BUDD, F.R.S.,

Professor of Medicine King's College, and Physician King's College Hospital.

Reported by DUNCAN FERGUSON, Esq., late House Physician King's College Hospital.

I come here to-day to commence the usual winter's course of Clinical Lectures under circumstances of peculiar interest. During the vacation, cholera has raged like a pestilence in the town, and the doors of this hospital have been freely opened to receive its victims. As the object of these Clinical Lectures is to direct your attention to what is most interesting or instructive in the wards of the hospital, you might well expect that I should take the first opportunity to speak of the terrible disease to which, for some time past, we have been devoting most of our time and thought, and which has turned our attention aside from other diseases.

The first case of cholera was brought into the hospital on the 5th of July; and the last, of which I have any record, on the 3rd of October.

During this interval of three calendar months, from the 4th of July to the 4th of October, which embraces very nearly the time during which cholera has prevailed extensively in London, there were brought into this hospital 113 persons ill of cholera. Of these, 41 died, or rather more than 1 in 3.

This rate of mortality, terrible as it is, has been much exceeded under similar conditions at other times. In 1837, while I was physician to the Seamen's Hospital, Dreadnought, cholera broke out there, and in the space of three weeks, 20 persons were attacked, of whom 12 died, in spite of the most prompt and diligent attendance.

This led me to examine the records of the Seamen's Hospital during the former visitation of cholera, in 1832, which were most carefully kept; and I found that in the Dover, a vessel fitted up at that time as a cholera hospital for seamen in the port of London, out of 160 patients, most of them robust men, well nourished, and in the prime of life 95, or more than 4 in 7, died.

The rate of mortality in our own Hospital, during the present epidemic, has not been uniform. It was much higher at the commencement of the epidemic than in its middle and towards its close.

In the first month, that is, from the 4th of July to the 4th of August, 22 patients were admitted with cholera, and of these 14, or very nearly two-thirds, died.

In the second month, from the 4th of August to the 4th of September, 55 were admitted, of whom 20, that is, 1 out of 11, or rather more than 1 in 3, died.

In the third month, from the 3rd of September to the 4th of October, 36 were admitted, of whom 7 only died, or less than 1 in 5. Or, reducing these different proportions to a common scale by the rules of arithmetic, it appears that the rates of mortality in the three consecutive months, were as 35, 23, and 11 respectively.

Now, you must not suppose that the gradually diminishing mortality, as time wore on, resulted entirely, or even mainly, from our having acquired greater skill in treating the disease. We cannot comfort ourselves with any such flattering belief.

In former epidemics, the rate of mortality has generally been highest at the onset, and has grown less in the same way as the epidemic declined, without our being able to ascribe the lessening mortality to greater skill in the treatment of the disease.

In 1832, the first cases of Cholera occurred in the spring, and the disease did not disappear from the metropolis till the January following. Its greater mildness, as the epidemic approached its termination, is shown by the records of the Dover, to which I just now referred. Of 137 cases admitted from the 20th of May to the end of September, 76, or more than 5 in 8, proved fatal; while of 21 patients admitted in the last three months of the year, when the epidemic was coming to a close, 15 recovered.

It seems, indeed, to be a law, to which there are very few exceptions, that in epidemics of cholera the rate of mortality is highest at the commencement, and becomes greatly less as the termination of the epidemic draws near.

Again, the rate of mortality among our hospital patients has varied considerably with age. The average rate of mortality, taking all ages together, was, as we have seen, 41 in 113, or rather more than 1 in 3. Now, out of the 113 patients, there were 37 of the age of 40, or upwards; and of these 18 died and 19 recovered; the rate of mortality was 1 in 2 very nearly. If we deduct these 37 cases, there remain 76, in persons under 40, of whom 23, or less than 1 in 3, proved fatal.

So that, while the rate of mortality in persons of 40 and upwards was very nearly 1 in 2, in persons under 40 it was less than 1 in 3.

Now this greater rate of mortality in persons past the meridian of life is not peculiar to our recent experience. It is a general fact, and was exemplified still more strikingly in the Dover in 1832. I have already stated that the rate of mortality in the Dover, taking all ages together, was rather more than 1 in 7. Now, of the 160 patients treated there, there were 22 who were 50 years of age, or upwards, and of these only 2 recovered; the age of each of these two was 55; of 13 who were above 55 years of age, not one recovered.

Persons who have passed the meridian of life, not only die in greater proportion than others when attacked, but are also more prone to have the disease. Of the 113 patients treated in this Hospital in the last three months, 39 were from 20 to 40 years of age, and 31 from 40 to 60. The number of patients from 40 to 60 years of age was, therefore, not very far short of the number from 20 to 40. Now, it must be plain, that, among the poor of London, the persons between 20 and 40 greatly outnumber those between 40 and 60; so that these figures lead to the conclusion, that persons from 40 to 60 are more prone to take the disease than persons between 20 and 40.

The greater liability of persons in advanced life to take the disease was shown more clearly still by the records of the Dover in 1832. The cases admitted into the Dover, all occurred in sailors, persons similarly circumstanced, and leading the same kind of life, who were admitted without any restriction, and are therefore well adapted to show the influence of age, within certain limits, on the liability to cholera. Of the 160 patients received into the Dover, more than one-third were 40 and upwards. By an existing regulation, the ages of all sailors who enter the port of London are registered. In 1833, I obtained permission from the authorities of the Custom House to examine these registers, and found, that out of [illegible] taken consecutively, considerably less than 1 in 5 had arrived at the age of 40. The predisposing influence of advanced [illegible]

ages still greater. [illegible] of the sailors [illegible] hospital with cholera, more than 1 [illegible] [illegible] of 50 or upwards; whereas [illegible] at the Custom house, less than 1 in [illegible] [illegible]; so that the number of sailors struck down with cholera was more than [illegible] it would have been were all ages equally liable to the disease.

I have been more particular in stating these points, because the lessening rate of mortality, as the epidemic wore on, and the higher rate of mortality in persons past the meridian of life, and the undue proportion of such persons struck down, are not peculiar to our own personal experience, but are examples of general facts which, from their being general facts, are of deep significance in the pathology of the disease; and which must be borne in mind and considered before we can form any just estimate of the relative efficacy of different plans of treatment.

The fact, that persons past the meridian of life are struck down by cholera in higher proportion than others seems to merge in a fact more general still.

It has been clearly shown by the returns of mortality from the different divisions of the Indian army, that hard service and long marching greatly increases the disposition to take the disease.

When two regiments come together to a new encampment, that regiment which has been most exhausted by hard marching almost invariably suffers the most. Dr. Lorimer, in a report on Cholera as it appeared among the native troops of the Madras army, on the line of march from one station to another, from 1820 to 1814, showed that the number of men struck down by Cholera, other circumstances alike, increased with the length and duration of their march.

Now, in the record of the cases brought into the hospital in the early part of the epidemic, for which I am indebted to Mr. Duncan Ferguson, there occur many such brief notes as these, in the history of the different patients—"Is of disorderly habits," "has been very intemperate," "has been half-starved."

Many instances are repeated from month to month, in which great dread of the disease, or some other depressing emotion, is generally supposed to have brought on the attack.

We have no collected facts which enable us to estimate the degree of influence which the several conditions to which I have just referred have in increasing the liability to Cholera; but there can be little doubt that their united influence is great.

It would appear, then, that advancing age, great bodily fatigue, depressing emotions, intemperate habits, and other circumstances that diminish the vital energy, increase the disposition to take the disease. Whence we must infer that the young, and the strong, and the bold, and the sober, although the mortality among them, too, is great, are often exposed to the poison without suffering from it. They must have a power within themselves that in some degree resists or controls its action.

I am happy to tell you, that none of the medical officers of the hospital have had the disease in any degree; and that not one of the many students who have given devoted attention to the cholera patients, have suffered in consequence, more than by occasional slight diarrhœa. Several circumstances followed, however, in the hospital early in the epidemic, which tended strongly to convince us that the disease is, in some way or other, infectious.

In the month of June, when cholera was threatening to become epidemic, the Committee of Management fitted up two unoccupied rooms for the reception of cholera patients in the building contiguous to the hospital, which they had just purchased: and, at first, all the persons ill of cholera brought to the hospital were placed in those rooms. In the course of a week or two, two of the nurses employed there took cholera and died of it; and a woman who nursed her child, ill of cholera in one of the rooms, also took it, but recovered.

On account of these events, the rooms in question were emptied and shut up; and the cholera patients were transferred to wards in the hospital on the west side of the building. There are, as you know, two wards or rooms on that side of the building on each floor, which are at right angles, like two contiguous sides of a square, and which [illegible] angle, by a short open passage in which [illegible] water-closet, which is common to both.

The men were placed on the floor usually occupied by [illegible] patients, in one of the wards; [illegible] at right angles to it, and communicating with [illegible] by the short open passage, and having the common water-closet, being still occupied by surgical patients.

The women were placed on the floor above, in a corresponding ward; the ward opening into this at right angles being there left empty, for the purpose of being cleaned. Soon after the cholera patients were thus transferred to the wards of the hospital, two of the surgical patients in the ward opening into that in which the men ill of cholera were placed, took cholera and died of it. Five persons brought into direct communication with the cholera patients had then been attacked with cholera in the hospital, and not a single patient had taken it in

any other ward, nor a single nurse or other person engaged in other parts of the house.

It was almost impossible to resist the conviction that the cholera patients brought to the hospital had been the instruments for infecting, in some way or other, these five persons.

In consequence of these occurrences the persons ill of cholera in the Hospital were shifted again, and were now placed in wards on the east side of the building, which do not communicate directly with any others, and which are separated from those on the west side by the passage which runs, from north to south, through the whole length of the building. This second transfer took place on the 10th of August.

Before this happened, some other circumstances had occurred, within our own observation, evincing great concentration of the poison in particular places.

On the 19th and 20th of July, 5 persons ill of cholera were brought to the Hospital, 3 on the first of these days, and 2 on the second; all of the same family, and from the same house, No. 3, Bolton-street, Kennington.

On the 26th of July, a woman, 52 years of age, was brought from a house in Yate's-court; and, on the 28th, a man, 72, (her husband,) was brought from the same house.

On the 4th of August 2 children, brother and sister, were brought from No. 11, Birch-lane; and on the following day 2 other children, of the same family, were likewise brought,—all ill of cholera.

On the 7th of August a man, aged 40, was brought from 14, Endell-street; and on the 8th, another person, one of his children, from the house.

By this time, also, public attention had been directed to the fact, that cholera was especially rife in Bridge-street, Blackfriars, along the course of the Fleet-ditch, and along the line of other sewers, especially near their termination in the Thames; and generally in the low and ill-drained quarters of the town.

These circumstances—the occurrence of five cases of cholera in the hospital among the comparatively few persons brought into direct communication with the cholera patients, while all other persons in the hospital escaped;—the instances I have mentioned, where several persons were brought from the same house, showing great concentration of the poison in particular places;—and the notorious fact, that cholera was especially rife in the low and ill-drained quarters of the town, and in the line of the sewers in the low parts of the town, where their contents are apt to stagnate—these circumstances led me to suspect, that the discharges from the cholera patients might, in some way or other, be instrumental in communicating the disease; and, in consequence, I now ordered, that a solution of chloride of zinc should be placed in the night-stools of the cholera-patients, and that it should be liberally poured, night and morning, into the water-closets, through which the discharges passed. The first part of my request was, I believe, neglected after a few days; the second part has been strictly complied with. The request was granted the more readily from its entailing very little cost.

Since the second transfer of the cholera patients took place, no fresh case of cholera has occurred in the hospital, although more than twice as many cholera patients have been taken into the hospital since as had been taken before. Before the transfer, to which I allude, had taken place, thirty-six patients ill of cholera had been admitted, and seventy-seven have been admitted since.

I have now mentioned the most striking general circumstances that have occurred within our recent experience at the Hospital. I shall not enter into any detail of individual cases. From the want of a sufficient number of clinical clerks, and from our being all so much occupied in ministering to the sick, the notes taken of any of the cases are very scanty and imperfect. I shall, therefore, content myself with making a few general remarks on the course of the disease, and on the morbid changes that are commonly found in the body after death.

(After giving a sketch of the course of cholera, and its various results, Dr. Budd proceeded).

I have now given you an account of the symptoms of cholera. We may next consider which of these are primary and fundamental.

It seems to me to be clear, that the rapid and profuse drain from the intestinal canal, and the state of blood which this induces, is the cause of all the other striking symptoms of the stage of collapse: of the coldness and blueness of the surface, of the shrinking of the body, of the cramps, of the suppression of urine, of the sense of oppression at the chest, and of the hoarse and whispering voice.

This appears to me to be proved by the remarkable experiment often made in this country in 1832, of injecting into the veins, during the stage of collapse, a large quantity of water, in which had been dissolved some of the salts contained in blood. In the Drummond-street Hospital, in Edinburgh, 156 patients were treated in this way: ℥ss. of muriate of soda, and ℈iv. of sesqui-carbonate of soda were dissolved in ten pints of water, at a temperature varying from 106° to 120° Fahr.; and this was injected slowly into the veins during the stage of collapse; half an hour being spent in the gradual injection of about ten pints.

I will read to you, from an article on Cholera, in the Library of Medicine, written by myself about ten years ago, an abridgement of the account of these experiments that was published by Dr. Mackintosh, who was Physician of the Hospital at the time, and under whose superintendence and direction the experiments were performed.

"After the injection of a few ounces, the pulse, which had ceased to be felt at the wrist, becomes perceptible, the heat of the body returns. By the time three or four pints have been injected, the pulse has become good, cramps have ceased, the body, that could not be heated, has become warm, and, instead of a cold exudation on the surface, there is a genial moisture; the voice, before hoarse and almost extinct, is now natural; the hollowness of the eye, the shrunken state of the features, the leaden hue of the face and the body, have disappeared, and the expression has become animated, the mind cheerful; restlessness and uneasy feelings have vanished; vertigo, noise in the ears, and sense of oppression at the præcordia, have given way to comfortable feelings; thirst, however urgent before the operation, has ceased. The secretion of urine was soon restored; but in this we were more frequently disappointed than in any of the other favourable symptoms. But these promising appearances were not lasting; the discharges continued, and became even more profuse; the patient soon relapsed into his former state, from which he might again be roused by the repetition of the injection; but the amendment was transient, and the fatal period not long deferred."

These remarkable experiments, which, as I have stated, were many times repeated, show that the feebleness of the pulse, the coldness and blueness of the surface, the cramps, the whispering voice, the vertigo, noise in the ears and sense of oppression of the chest; the thirst—all the most striking symptoms of the state of collapse, are owing to the loss of the water of the blood. There can be no doubt, also, that the suppression of urine results mainly from the profuse drain through the bowels, and the thickened state ot the blood which this induces

It would seem, therefore, that the primary and fundamental symptom of cholera, on which all the others are dependent, before reaction takes place, is the rapid and profuse drain through the intestinal canal. Cases are stated now and then to occur which appear to contradict this doctrine; cases sufficiently marked as cholera by cramps, and by coldness and blueness of the surface, and by the circumstances under which they occur, which prove fatal very rapidly, before any discharges have taken place. It has been inferred from such cases that cholera is produced by a virus, which is capable of causing rapid death by its direct action on the nervous system, without producing intestinal discharges.

Now, such cases are extremely rare. I have never met with a single instance of the kind among several hundred cases that have fallen under my own observation; and in this respect my own experience accords with that of several others who have had large experience during the late epidemic, whom I have questioned on the subject.

I do not, however, deny the occasional occurrence of such cases. I believe that such cases do occur; but that death is occasioned in them, as in others, by a rapid drain into the intestinal canal, which kills by the change it induces in the blood, and by the shock it gives to the system, before any discharges from the stomach and bowels have taken place: that, in fact, the stomach and intestines are full of the "rice-water," though none has passed away.

It seems to me, therefore, in spite of the occasional occurrence of such cases, that the profuse and rapid drain through the intestinal canal is the fundamental and primary symptom of cholera; and that it is the cause of the other symptoms of the stage of collapse.

One of the chief causes of the secondary fever is probably the suspended action of the kidney. In almost all cases where the collapse has been deep and prolonged, the urine passed for a day or two after re-action has taken place is scanty, and contains albumen. In cases that turn out well, the urine soon becomes more abundant, and the albumen disappears. In others, this favourable change does not take place. In a man, who was in the hospital under my care in the early part of the epidemic, re-action took place, the secondary fever came on, but the secretion of urine was not restored, and death occurred four days afterwards, evidently from the long suspended action of the kidney.

There are two other circumstances which may also have a share in causing the secondary fever. These are, the unnatural state of the blood, produced by the intestinal discharges, and the absorption of noxious matter from the intestinal canal, which may take place when the discharges cease, and absorption at the surface begins again.

Now, the defective action of the kidney, after reaction has taken place, is owing, most probably, to mechanical conditions; to the obstruction of the capillaries of the kidney by the previously thickened blood; and to the still existing deficiency of water in the blood.

It appears then still, after considering the whole course of cholera, that the rapid and profuse drain from the intestinal canal is the primary and fundamental symptom of the disease; that the poison, whatever it be, that causes the disease, has an exclusive action, or almost an exclusive action, on this part.

I will now briefly call your attention to the morbid changes found in the dead body.

Where death occurred during collapse, the body is of course shrunk, and the lips, and ears, and extremities have a blue or leaden hue, as during life. The body and limbs are very rigid from strong contraction of the muscles after death.

The chief marks of disease are found, as might have been expected, in the intestinal canal; and are most of them well preserved in the beautiful series of preparations on the table,—for which I am indebted to my friend, Mr. Busk.

The stomach and small intestines are, externally, of a pale rose-colour, from unusual accumulation of blood in their vessels.

The mucous membrane of the stomach and intestines throughout is generally more or less coated with the pasty substance of which the flakes in the discharges consist; and when this is wiped away, that of the stomach and small intestines appears thickened, and the villi are enlarged: appearances owing to their being charged with the fluid of which the intestinal discharges consist. By drawing the coats of the intestine between the finger and thumb, and using some pressure, a white, opaque fluid is squeezed out, and the membrane regains its natural thickness and appearance. It seldom presents the appearances usually considered indicative of the process of inflammation. But the most striking change discovered in the intestinal canal in this stage of the disease, is the broken state of the glands,

or follicles, of the mucous membrane. The glands of Brumner, the glands of Peyer, the solitary glands of the small and of the large intestine, are all swollen and much more conspicuous than natural.

In the lower part of the ileum the solitary glands look like small round heads projecting from the surface of the membrane.

All this is well shown in the preparations before you.

The mesenteric glands, also, are generally somewhat enlarged.

The gall-bladder is generally found distended with dark green, or olive-coloured bile; which is the more worthy of remark from the complete absence of bile in the intestinal discharges.

No morbid appearances are found in any other organ, except such as are fairly attributable to the changed colour and consistence of the blood.

In persons who die soon after re-action has been established, or after a protracted cold stage, the intestinal canal is found less congested, the mucous membrane is less swollen, and the glands or follicles are less conspicuous. In some cases small portions of the mucous membrane are found of a dark red colour from ecchymosis, and occasionally the membrane at those spots is found in a state of gangrene. These appearances are observed chiefly where the cold stage has been unusually protracted, and the intestinal discharges during life have contained blood. They are well preserved in three of the preparations before you.

In persons who die during the secondary fever, appearances like those produced by pneumonia are frequently found in one lung, or in both lungs, especially in the lower lobe.

No other organ presents any constant or characteristic changes, except such as are attributable to the physical characters of the blood.

The appearances observed after death, as well as the symptoms, show, then, that the poison of cholera, whatever it be, exerts its chief action on the intestinal canal.

I have now stated to you the substance of what we have observed here of the symptoms and morbid anatomy of cholera.

You are all aware, that public attention has been lately directed to the discovery made at Bristol, by Mr. Brittan and Mr. Swayne, of the almost constant existence of peculiar microscopic objects in "rice-water" discharges of cholera. These objects were first seen in July last, and objects like them have since been found in the air and in the water of infected districts.

Before you are some drawings of these objects; and you may presently have an opportunity of seeing some of the objects themselves through the microscope on the table.

I am myself far too ignorant of the microscopic appearances of low vegetable organisms to venture to express an opinion as to their nature. Further than that, they seem to me to be different from the ordinary products of a diseased mucous membrane.

Some of the objects found in the intestinal discharges, and some of those obtained by Mr. Brittan from the air, have been carefully examined by Mr. Quekett, of the College of Surgeons, who, (a great authority in such matters,) in a letter published in the *Medical Gazette*, has expressed his belief in their identity, also his belief that they are of a fungoid nature. Some other persons, practised in microscopic researches, have expressed, I believe, the same opinion.

The discovery of these objects has revived, in more definite shape, a theory that was much discussed after the last epidemic of cholera in this country; namely, that the disease is the effect of some extremely minute organism, vegetable or animal, which finds its way into the human body, and there germinates or breeds. It is right that a theory of this kind should be received with great caution.

At our next meeting, when I shall have to speak of the remedies we have lately tried in the treatment of cholera, I will endeavour to lay before you what I think can fairly be said for and against the doctrine, that the disease is so produced.

ORIGINAL CONTRIBUTIONS.

ON ALCOHOL, METHYLE, AMYLE, CYANOGEN, AND AMMONIA.

By Dr. SHERIDAN MUSPRATT,
Professor of the Liverpool College of Chemistry, Author of several Chemical Works, &c.,

In the distillation of all liquids which have undergone the vinous fermentation there is obtained an alcohol more or less dilute. Brandy contains from 50 to 52 per cent. of alcohol; rectified spirits of wine have 66 to 70 per cent.; absolute alcohol is obtained by saturating strong spirits of wine with chloride of calcium and distilling the solution. The chloride of calcium retains the water. Alcohol is highly inflammable, and its combustion, with a sufficient supply of oxygen, yields only carbonic acid and water.

$$\underbrace{C_4\,H_6\,O_2}_{\text{Alcohol.}} + 12O = 4\,CO_2 + 6\,HO$$

The purity of alcohol is known by its specific gravity. It should contain no essential oil. If any be present, sulphuric acid will produce a red colour in the menstruum. Vogel states, that nitrate of silver is a most delicate test for the oil, for, when added to alcohol containing it, subsequent exposure to the sun's rays will communicate a red colour. Alcohol is most useful in inorganic and organic chemistry, both as a solvent and precipitant. All those inorganic salts, deliquescent in the air, are soluble in this menstruum, with the exception of carbonate of potassa. Most of the organic acids are soluble in alcohol, and a great number of the salts which these acids yield with inorganic bases. Soap, for instance, contains stearic, oleic, and margaric acids, *i. e.*, soap is oleate, stearate, and margarate of soda. It is soluble in alcohol. Some of the soap solutions are used in medicine, as tincture of soap, opodeldoc, &c. Alcohol is decomposed by acids, giving compounds with their radical. We will discuss the action of the principal acid—sulphuric acid—upon alcohol. Neutral sulphatoxide of ethyle is unknown.

$$C_4\,H_5\,SO_4 \text{ or } ESO_4.$$

The bisulphatoxide, often described as sulphovinic acid, can be obtained immediately by passing the vapour of ether into hydrated sulphuric acid.

$$\underbrace{C_4\,H_5\,O}_{\text{Ether.}} + 2\,HSO_4 = \underbrace{C_4\,H_5\,SO_4,\,HSO_4}_{\text{Bisulphatoxide of Ethyle.}} + aq$$

Gregory states, the purest bisulphatoxide of ethyle is produced when sweet oil of wine is gently heated with four parts of water. It is decomposed; etherole, in the form of a yellow oil, separating, while the bisulphatoxide dissolves in the water. Bisulphatoxide of ethyle forms an extended series of salts. The formulæ of a few of the leading ones I shall place before you.

Sulphatoxide of ethyle and of hydrogen	$E\,SO_4,\ H\ SO_4$
Sulphatoxide of ethyle and of potassium	$E\ SO_4,\ K\ SO_4$
Sulphatoxide of ethyle and of barium	$E\ SO_4,\ Ba\ SO_4 + 2aq$
Sulphatoxide of ethyle and of calcium	$E\ SO_4,\ Ca\ SO_4 + 2aq$
Sulphatoxide of ethyle and of lead	$E\ SO_4,\ Pb\ SO_4 + 2aq$

The above salts are all soluble in water and spirits of wine. In the heat they are decomposed. The several products of the decomposition are etherole, alcohol, sulphurous acid, olefiant gas, &c. When the above-cited compounds are distilled with quicklime, under 300°, they are entirely converted into sulphates, sulphatoxide of ethyle and etherole. Sulphovinates, heated in a dry alembic with hydrate of baryta, give neutral sulphates and alcohol, *e. g.*

$$SO_4,\ K\ SO_4,\ HO\ Ba\ O = K\ SO_4,\ Ba\ SO_4,\ \underbrace{EO\ HO}_{\text{Alcohol.}}$$

There are compounds of ethyle with nitric, hyponitrous, carbonic, and oxalic acids which are described in all general works upon the science. The sulphides and sulphocyanides of ethyle and methyle, the radical of wood spirit, have occupied a great portion of the attention of chemists for some time. Löwdig, Kopp, and Weidmann, decomposed the bisulphide of ethyle with nitric acid, and obtained an acid which they represented by the formula

$$C_4\ H_5\ S_2\ O_4 + HO$$

A similar acid to this I procured from the sulphocyanide of ethyle, by acting upon it by nitric acid,

$$C_4\ H_5\ S_2\ O_5 + HO$$

It has been broached the acids are identical. In a short time the problem will most likely be solved, as I am at present engaged upon the subject. The bisulphide of ethyle is obtained by distilling together three parts of sulphovinate of lime with about the same quantity of bisulphide of potassium. It has a most offensive smell, so foul that it requires strong nerves to work with it. The formula is—

$$C_4\ H_5\ S_2$$

Sulphocyanide of ethyle is most difficult to obtain in large quantities. The best method of preparing it is to distil in a retort, equal measures of strong solutions of sulphovinate of lime and sulphocyanide of potassium. The capacity of the retort must be twelve times that of the space occupied by the mixture, to prevent any of the solution passing over into the receiver, which it is apt to do, owing to violent intumescence that occurs at intervals. The decomposition which takes place may be represented by the annexed equation:—

$$\underbrace{C_4\ H_5\ SO_4,\ Ca\ SO_4}_{\text{Sulphovinate of lime.}} \qquad \underbrace{KC_2\ NS_2}_{\text{Sulphocyanide of potassium.}}$$

Yield:—

$$\underbrace{C_6\ H_5\ S_2\ N}_{\text{Sulphocyanide of ethyle.}} \qquad \underbrace{K\ SO_4,}_{\text{Sulphate of potassa.}} \qquad \text{and } \underbrace{Ca\ SO_4}_{\text{Sulphate of lime.}}$$

Sulphocyanide of ethyle, discovered by Liebig, and studied by Cahours, is an oily and very dense liquid, possessing a strong alliaceous odour. The latter chemist has stated that "pretty concentrated nitric acid dissolves it with the aid of heat; but that upon cooling, it separates again completely."

This is not the case. Rather strong nitric acid decomposes the sulphocyanides of ethyle and methyle with great rapidity, affording acids which will be subsequently described. To obtain hyposulphathylic acid, about an ounce and a half of sulphocyanide of ethyle, and the same quantity of tolerably concentrated nitric acid should be introduced into a retort, connected with one of Liebig's condensers, and a slight heat applied to the retort during the whole process. At first the action is very brisk, and attended by evolution of nitrous fumes, carbonic acid and nitric oxide. Sulphuric acid is also formed during the operation; the quantity, however, depending upon the concentration of the acid employed. If weak nitric acid is used, traces only of sulphuric acid can be detected in the liquid. The distillate must be repeatedly returned to the retort, so as to insure very little loss of oil. The menstruum, after four or five distillations, poured into a porcelain basin, and evaporated in a water-bath, evolves its last trace of nitric acid, a fluid like oil of vitriol remaining, possessing a slight alliaceous odour. This, when diluted with water in which it readily dissolves, saturated with carbonate of baryta, and filtered to remove the excess of carbonate and any sulphate of baryta, yields, on gentle evaporation, large crystals of hyposulphathylate of baryta, which are purified by re-solution in water and precipitation by absolute alcohol. The acid may be obtained in a state of purity by precipitating the baryta by sulphuric acid from the aqueous solution of the salt, filtering, digesting the filtrate with carbonate of lead, re-filtering and decomposing the solution containing the lead salt, by hydrosulphuric acid. When the sulphide of lead is separated, and the filtrate evaporated in a water-bath, the acid is left in a pure state. If the acid be fused with potassa, and the residue treated with sulphuric or hydrochloric acid, large quantities of sulphurous acid are evolved. It withstands a very high temperature before suffering decomposition; fumes of sulphuric acid first escape, and then sulphurous acid is eliminated. The taste of the acid is most disagreeable and acrid, and of this the salts also partake.

The acid is miscible with water and alcohol, in all proportions, and is very persistent. Hyposulphathylate of baryta is so very soluble in water, that it can only be obtained in fine rhombohedral prisms, by allowing a concentrated solution to evaporate slowly. It is also very soluble in spirits of wine and ether, but insoluble in alcohol, which throws it down in beautiful satiny crystals. It parts with its water at 212°.

Formula:

$Ba, C_4 H_5 S_2 O_6$, or $Ba, E S_2 O_6$.

The dry crystals, when heated with soda-lime, give no indications of ammonia; fused with potassium, and tested with iron solutions, the absence of nitrogen is fully proved, and this is the most remarkable feature with regard to the acid. *In what form is the nitrogen of the sulphocyanide of ethyle eliminated?* Not *as ammonia*, for no *trace* of this *alkali can be detected. It must pass off in the form of nitrous acid or nitric oxide. No instance of similar decomposition has hitherto been observed, i. e., an acid containing no nitrogen has never yet been produced by the action of one nitrogeneous body upon another.* It will be as well to introduce the rational formulæ for the baryta, lead, and copper salts of this singularly-formed acid:—

Hyposulphathylate of baryta .... $Ba, C_4 H_5 S_2 O_6 + aq$

Hyposulphathylate of lead .... $Pb, C_4 H_5 S_2 O_6 + aq$

Hyposulphathylate of copper .... $Cu, C_4 H_5 S_2 O_6 + 5 aq$

When sulphocyanide of ethyle is gradually added to a mixture of chlorate of potassa and hydrochloric acid, a very violent action takes place, which is sometimes so brisk as to inflame the volatile product. The acid is the same as that produced *by the action of nitric acid* upon the sulphocyanide of ethyle. One equivalent of sulphocyanide of ethyle, three equivalents of chlorate of potassa, and seven equivalents of hydrochloric acid, contain the elements of one equivalent of hyposulphathylic acid, two equivalents of carbonic acid, one equivalent of nitric oxide, three equivalents of chloride of potassium, seven equivalents of water, and seven equivalents of free chlorine. The sulphocyanide of ethyle is readily acted upon by chlorine gas. When a stream of the gas is passed through it for some time, large quantities of chloride of cyanogen are formed, and there subsides a heavy yellow oil, which disappears when repeatedly washed. When a cold alcoholic solution of potassa is mixed with sulphocyanide of ethyle, and the mixture is allowed to stand for some days in a corked flask, decomposition occurs. The liquid assumes a blood red colour, and acquires a most singular odour; but there are no indications of the presence of ammonia. These reactions warrant further investigation. The sulphocyanide of methyle is prepared in a similar manner to the ethyle compound. Distil together equal parts of strong solutions of sulphate of methyle and lime, and sulphocyanide of potassium. The same precautions must be observed as those described under sulphocyanide of ethyle. Sulphocyanide of methyle is a heavy oil, possessing a disagreeable alliaceous smell. It is very readily decomposed by strong nitric acid, yielding an analogous compound to the hyposulphathylic acid. The acid possesses no smell, and is not easily decomposed by heat.

Formula for the baryta salt:—

$Ba, C_2 H_3 S_2 O_6$.

Hyposulphomethylate of baryta behaves like its analogue when heated in a test tube; water first passes off, followed by sulphuric and sulphurous acid fumes.

Formulæ of the lead and copper salts:—

$Pb, C_2 H_3 S_2 O_6 + aq$.

$Cu, C_2 H_3 S_2 O_6 + 5 aq$.

When a new compound is obtained in the ethyle series, we may, with a degree of certainty, assume the existence of a corresponding one in the methylic class of bodies; and although the latter series is not yet so extended as the former, still the analogues of all the sulphur and oxygen compounds of the ethyle combinations will, I am convinced, be brought to light; and as soon as this is the case, more definite conclusions may be drawn by chemists with regard to the basyles and salt radicals, upon which the whole fabric of chemical theory is, at present, based. We next come to the amyle type, products from which have lately been obtained by Mr. Medlock, of the Royal College of Chemistry. The name, amyle, has been given to the unisolated radical of a series of compounds, one of which, the hydrated oxide of amyle, has long been known as oil of potato-spirit, first analysed by Dumas, and afterwards investigated by Cahours. I shall incorporate portions of Mr. Medlock's paper in this lecture, in order to present to your notice the newest and most interesting compounds in the series. The substance serving for the preparation of the compounds, separates in the latter stages of the distillation of common corn spirit. "It is evident that the fousel oil, obtained in the distillation of spirit from barley, is perfectly identical with potato-oil. As obtained from the distillery, the oil still contains alcohol and water, but no other impurities. On rectification, it begins to boil 85°—185° Fahr.; after about one-third has passed over, the ebullition becomes constant at 132°—269° Fhr., the boiling-point of pure hydrated oxide of amyle; at this temperature the whole of the remaining liquid distils. It was evident that the product did not contain any oil of a higher boiling point. It remained, however, to ascertain the composition of the distillate which had been collected below 132°—269° Fahr. Chemists are acquainted with a variety of cases in which, of late, butyric and metacetonic acids have been observed, as products of fermentative processes very similar to the acetic fermentation; these processes are, however, up to the present moment, by no means so well understood in their different stages, as we understand the conversion of sugar into alcohol, or that of alcohol into acetic acid. The remarkable parallelism which formic, acetic, metacetonic, butyric and valerianic acids present in all directions, renders it, to a certain extent, probable, that, in what place soever we meet with these acids as products of fermentation, their formation is preceded by that of alcohols, similar to pyroxilic spirit, alcohol, and fousel oil. It appeared by no means improbable, that the first product of the distillation might contain the alcohol of metacetonic, or of butyric acid. In order to answer this question, to which my attention was particularly directed by Dr. Hofmann, I re-distilled the earlier distillates with particular care, removing the water by means of chloride of calcium, fractioning at intervals of five degrees, and separating the alcohol and fousel oil which came over in the beginning and at the end of the distillation. The result of repeated distillations of this kind, was the complete separation of this product into common alcohol and fousel oil, there being no other compound present." The action of chlorocarbonic acid—phosgene gas—upon fousel oil, gives rise to a most singular decomposition. The oil absorbs the gas with great rapidity, much heat being evolved during the process. When perfectly saturated with phosgene gas, hydrochloric acid is abundantly given off, and the liquid acquires a rich amber hue, and separates into two distinct strata; the lower one, consisting of a small quantity of accidental water, profusely charged with hydrochloric acid. The surface layer, mixed with an equal volume of distilled water, gives up a large quantity of hydrochloric acid. This acid liquid can be removed by a pipette. Plenty of acid still remains, therefore, protoxide of lead must be placed in contact with it and the whole finally dried by means of chloride of calcium. When the desiccated liquid is submitted to distillation, decomposition occurs; it blackens, and volumes of carbonic and hydrochloric acids are evolved, the boiling point rising from 150—302° Fahr., to 224°—135° Fahr., when it becomes stationary. The oily product which passes over during the escape of the gases, after rectification, becomes a perfectly clear and transparent liquid, possessing an agreeable odour quite different from the original mixture of fousel oil and phosgene gas. Its constant boiling point is 224°—435° Fahr. This compound is carbonate of the oxide of amyle.

$C_{10} H_{11} O, CO_2$.

The production of this compound is easy of solution. The action of phosgene gas on fousel oil is perfectly analogous to that which it exerts on alcohol; hydrochloric acid and chlorocarbonate of amyle being formed:—

$$\underbrace{HO, C_{10} H_{11} O}_{\text{Fousel oil.}} + 2C\left\{\begin{matrix} O \\ Cl \end{matrix}\right. = HCl +$$

$$\underbrace{C_{10} H_{11} O, 2C \left\{\begin{matrix} O_3 \\ Cl \end{matrix}\right.}_{\text{Chlorocarbonate of amyle.}}$$

The chlorocarbonate of amyle, however, is a most unstable compound; for, when brought into contact with water, it is decomposed into hydrochloric acid, carbonic acid, and carbonate of oxide of amyle:—

$$\underbrace{C_{10} H_{11} O, C_2 \left\{\begin{matrix} O_3 \\ Cl. \end{matrix}\right.}_{\text{Chlorocarbonate of amyle.}} \cdot HO = \underbrace{C_{10} H_{11} O, CO_2}_{\text{Carbonate of amyle.}}$$

$+ CO_2 \times H\,cl.$

The preparation of sulphocyanide of amyle is perfectly analogous to that of the described ethyle and methyle compounds.

Formulæ for the three:—

Sulphocyanide of ethyle .... $C_4 H_5 Cy S_2$
Sulphocyanide of methyle .. $C_2 H_3 Cy S_2$
Sulphocyanide of amyle .... $C_{10} H_{11} Cy S_2$

The last treated with nitric acid affords a similar acid to the hyposulphathylic and hyposulphamethylic acids. I will place the formulæ before you to prove their great analogy:—

Hyposulphamethylic acid. $H, C_2 H_3 S_2 O_6$
Hyposulphathylic acid .. $H, C_4 H_5 S_2 O_6$
Hyposulphamylic acid .. $H, C_{10} H_{11} S_2 O_6$

The methylic compound has been obtained by Dr. Kolbe as a product of the metamorphosis of chlorocarbo-hyposulphuric acid under the influence of galvanic electricity. The hyposulphate of the chloride of carbon, chlorocarbo-hyposulphuric acid, is the hyposulphamethylic acid in which three equivalents of hydrogen are replaced by three of chlorine,—*e. g.*:—

Hyposulphamethylic acid .... $H, C_2 H_3 S_2 O_6$
Chlorocarbohypo-sulphuric acid $H, C_2 Cl_3 S_2 O_6$

Hofmann states, and with good reason, that Medlock's acid is evidently identical with the compound prepared by Gerathwohl and Erdmann, as a product of the decomposition of the mercaptan of the amyle series.

There is a splendid field of discovery still open in the ethyle, methyle, and amyle class of bodies. I feel convinced before long we shall be able to append to the preceding lists, compounds of ethyle, &c., corresponding to the whole series of sulphur acids, by acting with nitric acid upon the higher sulphides of ethyle, &c., e.g.,

Tritimathylic acid...... $C_4\ H_5\ S_3\ O_5$
Tetratimathylic acid.... $C_4\ H_5\ S_4\ O_5$
Pentatrimathylic acid .. $C_4\ H_5\ S_5\ O_5$

We enter next upon cyanogen, the discovery of which by Gay Lussac, has proved of the greatest importance for organic chemistry. It is obtained by heating perfectly dry cyanide of mercury. Cyanogen is a permanent gas at the ordinary atmospheric pressure; but, compressed to one fourth of its volume, it is converted into the liquid state. It is soluble in water, posseses a penetrating odour, and burns with a purple red flame. Cyanogen is composed of two equivalents of carbon and one equivalent of nitrogen:

Formula, $C^2 N$. Symbol, Cy.

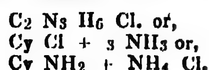
This compound radical combines directly with metals; potassium and sodium take fire and burn in this gas, exactly as they do in chlorine, giving cyanide of potassium and cyanide of sodium. The combination of cyanogen with metals, with oxygen, with hydrogen, with sulphur, with chlorine, &c., are extremely numerous. I have stated to you the interesting compounds of ferrocyanogen with many of the most important organic radicals. At present, we will only discuss the hydroferrocyanic and the hydroferricyanic acids and chloride of cyanogen. The first is prepared by mixing a cold saturated solution of ferrocyanide of potassium and an atomic proportion of strong hydrochloric acid;

agitate with ether, which rises to the surface with the hydroferrocyanic acid as a white crystalline mass, that must be dried under the air-pump. When desiccated it can be dissolved in alcohol, and the menstruum allowed to evaporate spontaneously. The aqueous solution of this acid is decomposed by boiling, into hydrocyanic acid and Prussian blue. The formulæ for the acid is given at the head of the annexed series :—

Ferrocyanide of hydrogen.....	H_2 Cfy
Ferrocyanide of potassium ..	K_2 Cfy
Ferrocyanide of lead	Pb_2 Cfy
Ferrocyanide of copper......	Cu_2 Cfy

A solution of ferrocyanide of potassium is an excellent test in the laboratory for determining the presence of copper,—a solution *containing one sixty-thousandth of its weight of oxide of copper* assumes a reddish brown colour with this re-agent. Ferrocyanide of potassium occurs almost pure in commerce. It is prepared by fusing in cucumber-shaped vessels, horn, hoof, and all substances rich in nitrogen, with two and a half parts of carbonate of potassa. The molten mass is, when cold, macerated with water, and the supernatant liquor when clear syphoned into vessels to crystallize. There is generally a great loss in this process, owing to the decomposition in solution of the cyanide of potassium into ammonia and bicarbonate of potassa. The air must be excluded as much as possible during fusion. Liebig and Gregory say, " why not fuse the animal matter with pure carbonate of potassa in close iron vessels, when from the absence of sulphate—always present in the American pearlashes and potashes—the pots would not be corroded." Cyanide of potassium would be formed, which, when digested with iron filings in open vessels, would give ferrocyanide. A solution of pure cyanide of potassium readily dissolves iron. If substances containing carbon and nitrogen are fused with pearlash at a red heat, the mass, as it comes from the furnace, does not contain any ferrocyanide, as this only forms when the black flux is boiled with water in open vessels, the cyanide of potassium dissolving the metallic iron, or sulphide of iron derived from the dried blood used or the corrosion of the pot, and being converted into ferrocyanide of potassium. The ferricyanide of potassium is also made on the large scale by passing chlorine gas into the ferrocyanide of potassium.

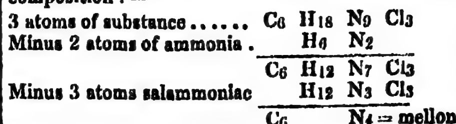
$$2\,(K_2\ Cy_3\ Fe) + Cl = K_3\ Cy_6\ Fe_2 + KCl$$



or

$$2\,(K_2\ Cfy) + Cl = K_3\ Cfy_2 + Kcl$$

Hydroferricyanic acid may be obtained by adding to recently precipitated ferricyanide of lead, weak sulphuric acid. On filtration and careful evaporation, the acid is obtained in yellowish crystals. These cyanogen compounds are most intricate, for in the heat, or when treated with alkalies and acids, they give rise to such strangely constituted bodies. A singular combination occurs from the union of dry chloride of cyanogen and ammoniacal gas. I passed chlorine gas through hydrocyanic acid and distilled, conducting the chloride of cyanogen formed through two tubes filled with chloride of calcium, into a dry flask, immersed in water, into which was also passing ammonia, dried over sticks of potassa. During the operation a great elevation of temperature ensued, and, after the lapse of half an hour, a beautiful, yellowish red, crystalline mass deposited on the recipient. This substance is completely soluble in hot water. When washed with absolute alcohol it loses its colour and becomes waxy white.



The subjoined formulæ represent the composition of this singular substance :—

$$C_2\ N_3\ H_6\ Cl.\ or,$$
$$Cy\ Cl + 3\ NH_3\ or,$$
$$Cy\ NH_2 + NH_4\ Cl.$$

The first is the empirical formula ; the others represent it as a compound of chloride of cyanogen with ammonia, or cyanamide with chloride of ammonium. When the substance is strongly heated, it fuses to a red liquid, evolving ammonia and chloride of ammonium, whilst a fine, yellowish, scaly-looking substance remains—probably mellon.

If so, the following equation represents the decomposition :—

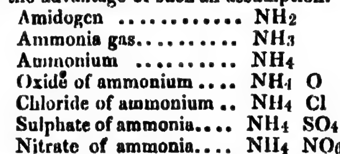
3 atoms of substance......	$C_6\ H_{18}\ N_9\ Cl_3$
Minus 2 atoms of ammonia .	$H_6\ N_2$
	$C_6\ H_{12}\ N_7\ Cl_3$
Minus 3 atoms salammoniac	$H_{12}\ N_3\ Cl_3$
	$C_6\ N_4$ = mellon

Compounds of chloride of cyanogen with ammonia are most numerous ; but I suppose the difficulty of preparing them, and the deleterious effects of the chloride of cyanogen, when inhaled, deters chemists from entering more fully into this new field of research.

As ammonia occupies so prominent a place in organic substances, it will be as well for me to advert for a short time to a few of its leading features, &c. This volatile alkali is now regarded by all chemists to be an amide of hydrogen,—amidogen being an hypothetical radical composed of one atom of nitrogen with two atoms of hydrogen.

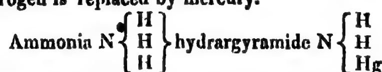
NH^2, or Ad

There is good reason for adopting this view, because when ammonia is passed over potassa heated strongly, a green mass is formed,—amide of potassium, *i.e.* ammonia,—amide of hydrogen,—in which the third atom of hydrogen is replaced by another metal.



Amide of hydrogen...... NH_2 + H

Amide of potassium...... NH_2 + K



Ammonium is the binamide of hydrogen, a compound which has not yet been isolated. It has, however, been obtained in combination with mercury as the amalgam of ammonium. The amalgam is formed by the action of electricity on chloride of ammonium, the negative pole communicating with this salt through a globule of mercury. By contact with water it splits into mercury, ammonia, and hydrogen.

As the existence of ammonium is now generally admitted, the ammoniacal salts are always represented as compounds of it. A few examples will show the advantage of such an assumption.

Amidogen	NH_2
Ammonia gas..........	NH_3
Ammonium	NH_4
Oxide of ammonium	NH_4 O
Chloride of ammonium ..	NH_4 Cl
Sulphate of ammonia....	NH_4 SO_4
Nitrate of ammonia....	NH_4 NO_6

Amidogen combines with metals and compound radicals. The amides of sodium and potassium are known in a separate form. White precipitate is a compound of amide of mercury with chloride of mercury, NH_2 Hg + Hg Cl. The amide of mercury is, in fact, ammonia, in which the third atom of hydrogen is replaced by mercury.

$$\text{Ammonia } N\begin{cases}H\\H\\H\end{cases} \text{hydrargyramide } N\begin{cases}H\\H\\Hg\end{cases}$$

Ammonia exists almost everywhere. Many agriculturists allow it to escape into the air from their farm recrements ; a most unwise plan, when it is so essential to vegetal life. There are, in fact, at present, a variety of substances which, sooner or later, will constitute races of vegetables, and contribute to the sustenance of thousands of beings ; even organic matter, which, during its disintegration, is resolved into carbonic acid, water, and ammonia ; finally, re-enters the vegetal organism in the persistent form, destined to repass through the same ceaseless cycle of vicissitudes and metamorphoses. I have endeavoured to present in this paper an epitome of the discoveries and theoretical views introduced into our noble science the last ten years, in the alcohol, ether, &c., class of bodies. What fruits may not another ten years bring forth ? Many investigations require repetition, some owing to improved apparatus and methods of research, others from the carelessness with which they have been conducted. Young chemists are springing up everywhere, too eager to enter upon the investigation of new products, before they are conversant with qualitative and quantitative analysis ; and without having worked upon known compounds, and perusing attentively, standard works upon all the theories and intricacies of science. To read the life of Bezelius, the illustrious Swede, or a sketch of Liebig, the sun of the scientific world, will give to all those interested in chemistry, an insight into the importance of a well-grounded knowledge of this, the most useful and sublimest of sciences. I have, for years, enjoyed the intimacy of the latter, to whom the whole world is indebted for valuable discoveries and useful applications of the grand science he professes to agriculture, physiology, and manufactures. The Swede has added more facts to chemistry than any other philosopher ; the German has thrown a beauty, simplicity and lasting interest over the science, which will, for ever, place his name first in the chemistry of agriculture and pathology. In him we see "there is no boundary to knowledge, nor the discovery of thought." Every fact has cost him immense labour to acquire, and labour to retain, and, although his students find him ready to pronounce upon the nature, properties, and history of almost every known inorganic and organic substance, still this prodigious mass of scientific information has only been acquired by indomitable perseverance and prodigious labour ; and, to show the infinity of science, how often have I heard even him exclaim, "*Ancora imparo!*"

CASE OF PLACENTA PRÆVIA.

By CHARLES WALLER, Esq., M.D.,
Obstetric Physician to St. Thomas's Hospital.

Having during the past week been called to another case of placenta prævia, I send the details for insertion in your journal, that they may be added to those already published in several preceding numbers. I am happy to say, that the case terminated very successfully. It will be seen, that by combining the two plans recommended in the management of these fearful complications of labour, the objects of both were accomplished, namely, by the complete separation of the placenta, the hæmorrhage was suppressed, whilst, on the other hand, by prompt delivery, the life of the infant was preserved.

Case 37.—On the morning of the 7th of October, was requested to visit a lady under the care of Mr. Dunn, of Norfolk-street, Strand, who gave me the following history of the case. His patient, a lady, aged thirty-seven years, was pregnant for the sixth time, and had passed her eighth month of gestation. Her former labours were unattended by difficulty or danger, and her children had all been born alive. On Saturday evening, September 29, she was alarmed by a sudden and profuse discharge of blood. Mr. Dunn being from home, his assistant attended : before his arrival the flooding had considerably abated, but great faintness was complained of. The patient was then sitting up : she was instantly placed in the recumbent position, when the discharge gradually ceased. When Mr. Dunn saw her the next day, Oct. 1st, there had been no return of the bleeding, and the only thing complained of was weakness from loss of blood. On his visit, Oct. 3rd, he found his patient on the sofa free from discharge, and feeling tolerably well ; during the night, however, after she had been in bed and asleep, the flooding suddenly returned, and Mr. Dunn was very hastily summoned to her assistance. When he arrived he found that the discharge had much lessened. An examination was made ; owing, however, to the nearly closed condition of the os uteri no satisfactory information was elicited. From that period there was no return of bleeding until Saturday evening, Oct. 6th, when it re-appeared suddenly. At this time the os uteri was beginning to open, though without any regular parturient efforts. At three o'clock on the morning of the 7th, the liquor amnii came away, and at seven o'clock the labour not advancing, my attendance was requested. At that time there was a mere drain from the uterus ; the patient exhibited the usual well-marked symptoms indicative of the serious loss of blood she had sustained ; the countenance was blanched ; the temperature of the body greatly diminished ; the pulse extremely feeble, although not inordinately increased in frequency ; the stomach retained nourish-

ment, and there was no restless agitation. On examination, I found (as I had previously been informed by Mr. Dunn,) the placenta attached directly over the os uteri, which was fully dilated. The entire circumference of the placenta was attached to the uterus, with the exception of a very small part of its thin edge anteriorly, through which the head could be distinctly felt; the greater part of the thick central mass was necessarily separated by the dilatation of the os. Before removing my hand, I detached the adhering portion from its uterine connexion, and removed the clots which had accumulated in the vagina, then carefully wiped the external parts with a napkin, and waited a few seconds to ascertain whether the operation had been attended with a renewal of the hæmorrhage: *not the slightest drain occurred.* As the parts were well prepared for delivery, and as the speedy removal of the child afforded the only chance of its life, I again introduced my hand, passed by the placenta, and turned the child with great facility; and, although the infant at birth showed but feeble symptoms of vitality, complete resuscitation took place after the usual means for the recovery of asphyxiated children had been had recourse to. I have since been informed by Mr. Dunn, that every thing has gone on favourably, both as regards the mother and the child.

The termination of this case was highly satisfactory. The loss of blood sustained by the patient had been so great that she would probably have sunk from exhaustion had the hæmorrhage been renewed; and I cannot but consider that the entire separation of the placenta, prior to turning, tended greatly to produce the desirable result, as by it those frightful gushes, which frequently take place during the operation of turning, were altogether prevented. In order to avoid the danger as much as possible, it was my plan formerly to pass my hand through the placental substance; but I am convinced that its entire detachment is more certain, more safe, and more easily accomplished, whilst the danger to the infant is by no means increased.

Finsbury-square, Oct. 13, 1849.

ON THE USE OF THE BISULPHURET OF CARBON IN CHOLERA.

By JOHN HASTINGS, M.D.

Having seen, in the course of the last few months, considerable benefit arise from the use of the bisulphuret of carbon, in that stage of diarrhœa in children, in which the sunken eye, shrunken features, feeble pulse, and wasted form denote that the patient is suffering from extreme exhaustion, I determined to try its remedial powers in the first case of cholera I was called in to, in the stage of collapse.

As the bisulphuret of carbon is but little known as a medicinal agent, it may not be uninteresting to mention, that it was discovered by Lampadius in 1796—Formula CS_2 — prepared by passing sulphur in vapour over charcoal heated to redness in a porcelain tube; and purified by distillation with the chloride of calcium. It is liquid, colourless, and the clearest fluid in nature, highly refractive, of the sp. gr. of 1250, boils at 110° Fahr., and does not freeze, according to my notes of Kemp's lecture, at 165° Fahr. below zero; hence useful for thermometers. (a) Dr. Pereira, however, says it freezes at 60° Fahr. below zero. It produces great cold by evaporation, is very inflammable, and difficult to be extinguished. It explodes in oxygen and the nitric oxide, if the vessels containing the gases are warmed. Sulphurous and carbonic acids are the products of its combustion in atmospheric air. It unites with alcohol and ether, but separates on the addition of water, with which it will not enter into combination, though it is soluble in the oils. Its taste is hot and pungent.

In 1842 it was applied by Dr. Turnbull (b) to the eye and ear in vapour, and also to some enlarged lymphatic glands. It was discovered by a Norwegian to be an anæsthetic body, and afterwards employed as such by Drs. Simpson and Snow on several occasions. It has been used by (a) Dr. Burgess and others, in affections of the skin. It has been administered internally in gouty and rheumatic affections as a stimulant and sudorific; also as an emmenagogue and restorative. It has also been employed as a counter-irritant.

Case 1.—On the evening of September 7th, I was requested by my friend Mr. Brunskill, of Upper Eccleston-place, Pimlico, to meet him in the Vauxhall Bridge-road, at a case of cholera. The patient was a retired tradesman, in easy circumstances, aged 65 years. He had always led a temperate life, and enjoyed tolerable health; his bowels had commonly a tendency to relaxation. For several days, he had suffered from diarrhœa, but did not send for his medical attendant, Mr. Brunskill, before yesterday. This morning he was sick, for the first time, after breakfast; the diarrhœa had become more frequent, and the evacuations assumed a rice-water appearance. As the day advanced these symptoms increased, the surface of the body grew cold, respiration was more hurried, and cramps made their appearance. His pulse was now thready, respirations thirty-six in the minute, breath and tip of the tongue cold, countenance livid, voice croaking, hands shrivelled and cold. He complained of great agony about the abdominal region, and the cramps of the lower extremities were so severe, that he could not be kept in bed. No water had been passed for four hours. He had been treated with calomel and opium in pills, and a chalk mixture containing catechu. We now determined on trying a tablespoonful of the following mixture every hour:—

℞ Carbon. bisulph, ♏ x.; vitelli ovi, (No. 1;) aq. destil, ℥vj. M.

Sept. 8, 1 p.m.—He was in every way improved, the bowels had acted once, and the discharge had a feculent odour; was free from vomiting, and no water had been passed. He had not suffered from cramps after the first dose of the mixture. Cont. mist.

Sept. 10, half-past 11, a.m.—Improving in all respects.

Sept. 12, 2 p.m.—He was now so much better, that the mixture was discontinued for salines, my visits ceased, and I have since learned, from Mr. Brunskill, that he recovered rapidly.

The re-action which this remedy occasioned in the preceding case was so striking and satisfactory to Mr. Brunskill and myself, that I decided on testing its efficacy on a more extensive scale, through the medium of the District Medical Officers, in Lambeth and other places, where cholera was prevalent; and the following reports are all I have yet been able to collect from these gentlemen.

The cases treated by the district medical officers are drawn up very concisely; their time being unceasingly occupied with professional calls, consequent on this epidemic, prevented their doing more than giving a bare outline of the symptoms and treatment. They have complied with my request, and treated only collapsed cases with the bisulphuret of carbon. I adopted this course, that there might be no doubt about the nature of the disease treated, although I risked its employment in cases which were *in articulo mortis.*

Dr. Fairbrother, of the London-road, Southwark, treated the following seven cases:—

Case 2nd.—Sept. 9th, a female, aged 20, residing at 18, Bradd-street, Cornwall-road, was seized with the ordinary symptoms of cholera, without premonitory diarrhœa, and the stage of collapse rapidly followed. Three grains of calomel were administered every quarter of an hour, in conjunction with a mixture containing ammonia and opium; as no amendment ensued after some hour's trial, it was abandoned, and a tablespoonful of the following mixture given every hour:—

℞ Carbon. bisulph, ♏ xv.; vitelli. ovi, (No. 1;) aq. destil., ℥vj. M.

Sept. 10.—As all the symptoms of collapse had disappeared, the mixture was discontinued, and the patient rapidly recovered.

Case 3.—Sept. 9.—Mrs. Sargent, aged 50, residing at 19, Temple-street, London-road, was pulseless, and in a state of intense collapse. She had been treated by a neighbouring practitioner with calomel and capsicum, before she came under my care. A table-spoonful of a mixture similar to the one given in the preceding case was administered every hour; several hours passed before there was much evidence of improvement; but by the time the mixture was consumed, complete re-action was realised, and she rapidly recovered.

Case 4.—Sept. 10.—Mr. Heath, aged 66, residing in Pitt-street, Elephant and Castle, was seized with cholera yesterday. Calomel, opium, and ammonia were used; but, as the patient gradually became worse, the bisulphuret of carbon was administered, as in the two preceding cases.

Sept. 11.—The vomiting, diarrhœa, and all symptoms of collapse had disappeared, re-action showed itself after a few doses of the medicine, and he rapidly recovered.

Case 5.—Sept. 14.—Mary Hibbert, aged 6 years, residing at 18, Bradd-street, Cornwall-road (the residence,, also, of Case 2), was pulseless, and intensely collapsed. This child, not having been subjected to any treatment, a tea-spoonful of the following mixture was given every half hour:—

℞ Carbon. bisulph., ♏vj.; vitelli ovi.; Aq. destill., ℥iss.

Reaction ensued in a comparatively very short time, and she quickly recovered without the aid of any other remedy.

Case 6.—Sept. 14.—John Randall, aged 65, residing at St. George's-passage, St. George's-market, was in the stage of collapse, when the bisulphuret of carbon was administered in the usual dose. It brought on re-action, and was discontinued. The patient was put under the influence of the sesquicarbonate of ammonia, but he eventually died from exhaustion.

Case 7.—Sept. 25.—A child, when first seen, was suffering from intense collapse. Ammonia and small doses of opium were frequently administered; but as no improvement manifested itself, after two hours' trial, I prescribed the bisulphuret of carbon, which at once arrested the sickness; a slight flush on the cheeks, with other signs of re-action, appeared, when the second or third dose had been taken, but these were of short duration, as the child *died* a few hours after.

Case 8.—Mary Garrett, aged 35, of 21, Temple-street, Elephant and Castle, was seized with cholera on Sept. 18. Calomel, in repeated small doses, with the sesquicarbonate of ammonia, was administered, but intense collapse rapidly set in, when the bisulphuret of carbon was resorted to; re-action speedily followed, ammonia and tonics were then employed, and she *recovered.*

Mr. Smyth, of Lambeth-walk, one of the Lambeth district surgeons, has given the bisulphuret of carbon in the following cases: at the same time he used that agent, he continued the calomel treatment.

Case 9.—Sept. 11.—Mrs. Gleeman, aged 30, 9, William-street, High-street, in the stage of collapse, took a table-spoonful of the following mixture every hour:—

℞ Carbon bisulph., ♏xv.; vitelli ovi, No. 1.; aquæ destill., ℥viii.

Re-action followed a few doses of the mixture, and she *recovered.* The first dose suppressed the vomiting.

Case 10.—Sept. 11.—Mrs. Watson, Noah's-ark-court, Westminster-bridge, aged 40. In this case the collapse was intense; a mixture similar to the preceding was administered, which immediately arrested the sickness, re-action speedily followed, and she recovered.

Case 11.—Sept. 14.—John Hughes, aged 4 years, residing at Duke's Head-court, had previously suffered from cholera. This child was collapsed when the bisulphuret of carbon was administered. It occasioned sickness, but brought on slight re-action. The child *died* from the consecutive fever. I have since learned that most of the mixture con-

(a) Elements of Materia Medica. By J. Pereira, M.D. 1849. Page 365.
(b) Medical Gazette, Nov. 5, 1842.

(a) Eruptions of the Head, Face, and Hands, by J. H. Burgess, M.D. p. 17 1849.

taining the bisulphuret of carbon was thrown away by the mother of the child, under the idea that the medicine was bad from the smell.

Case 12.—Sept. 16.—Mrs. Davis, aged 55, residing at 3, Harper's-walk, took the bisulphuret of carbon for several hours without vomiting whilst in the stage of collapse; but no reaction was developed, and she *died*.

Case 13.—Sept. 17.—Mrs. Keighley, residing at 5, Carlisle-row, was in the stage of collapse when the bisulphuret of carbon was given. It occasioned great sickness, and was discontinued in consequence, but not before reaction was established, and she eventually *recovered*. She was attended by Mr. Smyth's assistant.

Case 14.—Sept. 18.—Miss D., aged 35 years, residing at Boswell-terrace, was seized with Asiatic cholera early on the morning of the 18th September. She was seen by my assistant, who prescribed small doses of calomel, according to Dr. Ayre's plan of treatment. Her symptoms becoming worse, I was requested to see her at 10 a.m. I found her at that time suffering severely from cramps in the legs, arms, stomach, and dorsal muscles, with tongue cold, voice choleric, pulse scarcely perceptible at the wrists, hands and feet cold, and lips blue, indicating clearly a perfect state of collapse. I accordingly gave one tablespoonful of the following mixture every hour, still continuing the calomel treatment:—

℞ Carbon Bisulph., ♏ xx.; vitelli ovi (No. 1); aq. destill, ℥vj. M.

2 p.m.—Symptoms improved.

11 p.m.—A decided improvement, re-action having evidently set in.

At this time, the bisulphuret of carbon having been rejected from the stomach, and the patient being disinclined to continue the remedy, I advised its being discontinued, recommending a perseverance in the calomel treatment. When seen next morning, she was under the influence of mercury, rejected bilious matter from the stomach, and passed a copious bilious evacuation.

Consecutive fever came on, but in a mild form; and she is now perfectly recovered. In this case, the bisulphuret of carbon appeared to have had a decided effect in producing re-action.

Mr. Avery, of 3, Queen-street, May-Fair, one of the surgeons of the Charing-cross Hospital, has forwarded the following three cases, of which the first two were treated by Dr. Golding, one of the physicians to the Hospital.

Case 15.—A male adult, in an advanced stage of collapse from cholera, recovered, in the Charing-cross Hospital, under the use of the bisulphuret of carbon.

Case 16.—Another patient, in a hopeless state of collapse, was also treated, in the same hospital, with the bisulphuret of carbon, but died.

The following case was communicated to me (Mr. Avery) by Mr. Bostock, to whom I had forwarded some of the bisulphuret of carbon.

Case 17.—A soldier in the Tower was seized with the cholera on Friday, September 28; he was sent to the Regimental Hospital in Pimlico, where he was treated with the bisulphuret of carbon and recovered. He also took a few grains of calomel and saline injections. Bilious evacuations and water were passed on Saturday, and the Battalion Surgeon observes, "the medicine has been of essential service."

The following case was treated by Mr. Austin, of 3, Walker's-place, Rotherhithe.

Case 18, Sept. 15.—D. V., aged 23, unmarried female; arrived in London, from Reading, in good health, on Friday, the 14th, on which day her mother had died of cholera in the same house.

I first saw her at 8 o'clock on Saturday evening, (the 15th.) She had been purged a great many times since 12 at noon, and had also vomited frequently. Her countenance was shrunken and of a dusky hue, eyes sunken, conjunctiva injected as from weeping, tongue slightly coated and cool, but not cold, pulse rapid and very feeble, hands and feet cold; the former shrunken and dark coloured, but not blue, (washerwomen's hands); the lower extremities cramped severely, no urine passed since noon, and the last evacuation from the bowels exhibited the genuine rice-water appearance. The voice was husky and the epigastrium very hot. She took the bisulphuret of carbon, as prescribed by you, xv. minims to 6 oz., one tablespoonful every hour.

11 p.m.—She had taken two doses of the bisulphuret; her countenance was more shrunk and bluish, the tongue colder and more coated, pulse almost imperceptible, hands and feet very cold—the former deep blue and bathed in perspiration—cramps more severe, no urine passed, and four motions of rice-water appearance. The voice was choleric and with difficulty to be understood. Cont. mist.

Sunday morning, 5 o'clock.—Her colour was of a deeper blue, the tongue much more coated but warm, pulse quite lost, hands and feet warmer and moist with perspiration, cramps abated in some degree, conjunctiva intensely injected and œdematous, a flush in the cheek, which felt warm, no urine passed, and two motions, both coloured with blood. The voice was rather improved. Cont. bisulphuret.

8 a.m.—The countenance was improved, and the blue colour less intense; the tongue warm, and more coated; the pulse perceptible; the cramps had ceased; no urine; no motions; and the voice still improved. Cont. bisulph.

10 a.m.—Improved. No motions.
1 p.m.—Ditto. Ditto.
5 p.m.—Ditto. Ditto.

8 p.m. (24 hours from my first visit).—She was quite warm; the tongue enormously coated, and conjunctiva excessively injected; the shrivelled appearance of the hands was gone; and no urine had been passed. She spoke in a natural tone, and conversed freely. Cont. bisulph.

11 p.m.—Improved. Cont. bisulph.

Monday, Sept. 17, 10 a.m.—She felt well, but very weak; the tongue still coated as before, and conjunctiva likewise injected; but no motions, and urine had been passed in the night. She asked for nourishment, which was allowed. The bisulphuret was discontinued.

Tuesday.—Improved; she had passed two loose green motions.

Wednesday.—Improved; conjunctiva natural, and tongue clean. She had passed three motions as before.

Thursday.—She sat up, and eat a mutton chop with port-wine negus at one o'clock; and in the afternoon laid on the bed, and slept. In the evening, however, not having awoke, the friends were alarmed, and when I saw her, I could with difficulty arouse her. The pulse was natural; the head cool; the tongue clean; the hands and feet warm; the bowels had acted once, and urine had passed; nothing, in fact, ailed her but the drowsiness, which increased more and more during the night, with stertorous breathing, contracted pupils, total insensibility even to pinching and pricking, and on the following morning (Friday, the 21st) she *died*.

She took in all fifty minims of the bisulphuret of carbon, and no other medicine.

N.B. The vomiting ceased from the exhibition of the first dose.

Mr. Bell, of 46, Manor-place, Walworth, Medical Officer of St. Mary, Newington, has treated the following twenty cases, and favoured me with the accompanying observations:—

"I have tried calomel in large and small doses, but with very unsatisfactory results. The efficacy of the bisulphuret of carbon over every other remedy in cholera, the successful termination of the following cases goes far to prove; and if administered in an early stage of the disease, or even before intense collapse has set in, a speedy reaction may almost in every case be predicted with unfailing certainty.

"A peculiarity of its action is the fact of the stomach rejecting the first dose, while it retains the succeeding ones, three of which I have generally found sufficient to arrest the vomiting and purging, the latter being more frequently put a stop to than the former. Should the vomiting, however, continue, I have found a mixture composed of sod. sesquicarb. ℈ij., et aq. destillat ℥vj., capt. coch. amplum om. hora, eminently successful in arresting it. When thorough reaction has set in, I follow up the bisulphuret of carbon with stimulants until complete recovery takes place."

Case 19.—Elizabeth Elbourne, aged 50, of 29, Portland-street, Walworth. She was attacked with cholera, September 10. The bisulphuret of carbon was given, and the purging ceased, but the vomiting continued, which, however, was likewise arrested by the sesqui. sod., as mentioned above, and *recovery* took place on September 22nd.

Case 20.—Joseph Roleinsau, aged 18 months, of 8, Portland-street, was attacked September 10. The bisulphuret carbon was given, and he *recovered* September 14.

Case 21.—Ann Prince, aged 37, of 4, St. Peter's-street, Walworth, was attacked September 10. The bisulphuret of carbon was administered; the vomiting and purging ceased; stimulants were given; and she *recovered* September 15.

Case 22.—Frances Rich, aged 67, of 6, Little Pleasant-row, Walworth, was attacked September 11. The bisulphuret of carbon was administered, the vomiting and purging ceased, stimulants were given, and she was doing well up to the 24th, when the vomiting and purging returned, and she *died* September 26.

Case 23.—William Foley, aged 7, of 1, Metcalf-buildings, Walworth-common, was attacked Sept. 11; the bisulph. carb. was administered, the vomiting and purging ceased, and he recovered Sept. 15.

Case 24.—Robert Chester, aged 30, of 14, Trafalgar-street, St. Walworth road, was attacked Sept. 11; the bisulph. carb. was used, and he recovered September 15.

Case 25.—Sarah Churchman, aged 33, of Hawksbury Cottage, Dean's-buildings, Walworth, was attacked Sept. 12; the bisulph. carb. was used, the vomiting and purging ceased, and she recovered Sept. 23.

Case 26.—Maria Brown, aged 3, of 9, Prince's-street, Walworth, was attacked Sept. 16; the bisulph. carb. was used, the vomiting and purging ceased; stimulants were given, the vomiting and purging returned, and she died Sept. 20.

Case 27.—Mary Collins, aged 29, of 9, St. Peter's-street, was attacked Sept. 17; the bisulph. carb. was used, and she recovered Sept. 19.

Case 28.—Esther Wilson, aged 2, of 46, Portland-street, was attacked Sept. 18; the bisulph. carb. was used, and she recovered Sept. 29.

Case 29.—Ann Revitt, aged 39, of 6, Belgrave-place, Walworth, was attacked Sept. 19; the bisulph. carb. was used, the vomiting and purging ceased, and she recovered Sept. 23.

Case 30.—George Foley, aged 4, of 1, Metcalf-buildings, was attacked Sept. 21; the bisulph. carb. was used, the vomiting and purging ceased, and he recovered September 24.

Case 31.—Emma Millidge, aged 41, of 4, St. John's-street, Walworth, was attacked Sept. 18 the bisulph. carb. was used, the vomiting and purging ceased, and she recovered Sept. 21.

Case 32.—Charlotte Crate, aged 42, of 19, King's-row, Walworth-road, was attacked Sept. 21; the bisulph. carb. was given, the vomiting and purging ceased, and she recovered Sept. 24.

Case 33.—William Hardy, aged 3, of 7, Camden-street, Walworth, was attacked Sept. 21; the bisulph. carb. was given, the vomiting and purging ceased, but afterwards returned, and he died Sept. 22.

Case 34.—Sophia Roberts, aged 23, of 29, Portland-street, Walworth, was attacked Sept. 25; the bisulph. carb. was given, the vomiting and purging ceased, and she recovered Sept. 28.

Case 35.—William Barter, aged 39, 14, Grove-street, Walworth Common, was attacked Sept. 27: the bisulph carb. was given, and he recovered Sept. 29.

Case 36.—Mary Flight, aged 67, of 12, Trafalgar-street, Walworth, was attacked Sept. 25; the bisulph. carb. was given, and she recovered Sept. 28.

Case 37.—Jeremiah Minard, aged 26, of 29,

Portland-street, was attacked Sept. 24; the bisulph. carb. was given, and he recovered Sept. 26.

Case 38.—Silena Pople, aged 10, of 9, Camden-street, Walworth, was attacked Sept 30; the bisulph. carb. was given, the vomiting and purging ceased, but afterwards returned, and she died Oct. 2.

Although I recommended the bisulphate of carbon to be administered in minim doses every hour, I believe better and speedier results would have been obtained by three minim doses every quarter of an hour. This uncertainty is a disadvantage which attends the introduction of all new remedies. The re-action which this agent induces in the stage of collapse, cannot, I think, be ascribed to its stimulating powers, as all stimulants hitherto employed—however large the dose—have failed in their object. In some cases its effect has been so rapid, that nothing less than the destruction of the choleraic poison could account for it, and—as its chemical composition shows—it cannot do so by supplying the blood with the salts it has lost. The exhibition of calomel and other agents with the bisulphuret of carbon, by occasioning its rejection from the stomach, checked, I am convinced, in some cases, its beneficial action. Whether it will be found as generally useful as it has been proved to be in the foregoing cases, or more so, a few weeks no doubt will determine.

The following case has just reached me from Dr. Fairbrother, of the London-road, Southwark:—

Case 39.—Oct. 12.—A little boy, aged 8 years, of 4, Jonathan-street, Vauxhall, was attacked with cholera, Oct. 11th, and speedily went into decided collapse. A dose of calomel and opium was administered, and a few doses of a mixture containing sesquicarbonate of ammonia. When seen by me, he was blue, cold, and almost pulseless. A hot wet blanket was applied, and a tablespoonful of the following mixture was given every hour:—℞. Carb. bisulph. ♏ x., magnes. carb. gr. xx., aq. destill. ℥vj. M. The patient rallied after the third dose, and is now in a fair way of recovery.

Albemarle-street, October 16, 1849.

PROGRESS OF MEDICAL SCIENCE.

SCOTLAND.

[From our Edinburgh Correspondent.]

Since the several recent schemes for Medical reform have been under agitation, many of our brethren in Scotland have publicly expressed an opinion, that penalties against quackery should form no part of any new legislative measure for the improvement of the Medical Profession. They are for allowing the public a free choice between the avowed quack and the regular practitioner; they would have no coercion exercised over the public mind, when the bodily health is concerned, any more than in matters spiritual. They think the prohibition of quackery by Act of Parliament, at the instance of the Medical Profession, is as bad as State-intolerance in religion, or the custom of thirlage in agriculture. They would reject a protection which might be branded with the odious name of monopoly. Their scheme is, to leave the public the suicidal liberty of employing avowed quacks, while they propose only to inflict penalties on unlicensed practitioners, who assume the designations of regular Medical men.

It seems pretty plain that such sentiments are fully more prevalent in Scotland than in England, whether it be owing to the principles of universal toleration having taken deeper root here, or, what is more likely, owing to quackery being less luxuriant in the poorer soil of Scotland than in England, where it feeds on the fat of the land.

But, while it may be a wise and proper sentiment to say, that penalties against quackery should form no part of a legislative measure of Medical reform, and that the Medical Profession should not be called on to act the unpopular part of informers and prosecutors against the bare-faced impudence of quackery, it may be a failure of duty in the Medical Profession to permit the public to think that quackery is not so criminal as to merit coercion and punishment. The case, then, stands thus: the Medical Profession, as a body, are unquestionably of opinion that hundreds of lives are annually sacrificed, in the United Kingdom, to the Mammon of quackery; but it is not expedient, that in a case where they may be suspected of having an eye to their self-interest, that individual Medical men should be made the instruments by which these criminals should be brought to justice. But, surely it belongs to every Government, that seeks to deserve the character of being paternal, to take the necessary steps to put down the murderous nuisance of quackery as much as any of the offensive pestiferous nuisances of which so much is heard at present. Is it, however, really a matter of certainty that it is in the power of a Government to take effectual steps to put down quackery? The stamp-duty on patent medicines might be taken off. But what would be gained by that? As dangerous drugs might be sold even more freely than before. The Government might, however, refuse to authorize any drug of a very dangerous character without the production of evidence that the directions for using it were at least generally safe. There can be no objection to harmless drugs being sold even with the Government stamp. It is idle to think of forcing men to subject themselves to regular treatment. It is enough to prevent the unprincipled from putting them in jeopardy for the sake of gain. The homœopaths are secure against falling into this criminal position as long as they stick to their infinitessimals. They do not kill—they are merely chargeable with letting men die who might otherwise be saved. But what should a paternal Government do against the rash practice of self-taught hydropaths, or of such sects as that whose talisman is a narcotic poison like the lobelia? For both undoubtedly kill—notwithstanding that each employs a treatment of excellent service in judicious hands. Recent instances show how difficult it is to obtain a conviction, even with the most palpable evidence of death being the result of the treatment. In the case of Dinah Toothill, recently reported, as tried before the Coroner at Keighley, a prudent man might decline to pronounce on oath that the woman actually died of the savage treatment to which she was subjected; but no intelligent medical man will hesitate to say that hundreds of persons, under the like circumstances, would have lost their lives, had they been made to stand as long on the floor, naked, four times a day for a week, while cold water was kept pouring over the body; and had this out-Heroding of the cold affusion been terminated by the person being kept wrapped in a wet sheet for half an hour more, and, as if this were not sufficient, had two additional applications of cold water to the head been made in the night during the same period. Though the woman who was subjected to this treatment was menstruating at the time, the jury returned a verdict "died by the visitation of God." That hydropathy, in the hands of persons who understand something of the fragile nature of the living body, is capable of producing occasional good effects, we make no doubt; but if the rash and ignorant (and who but they will venture on such a step) be permitted to take up this practice, and to apply it as their sole remedy to all diseases, and in all their stages indiscriminately, how is it possible that death should not often be the result? It appears, that hydropathy is already discovered to be a profitable field by those who have to live by their wits. There is already an organization in the corps of unlettered Hydropaths—there are General Practitioners and Consulting Hydropaths; for, in the case just referred to, the active Practitioner, seeing the more he pushed the remedy the worse the patient grew, desired a consultation, and the Hydropathic consult judiciously advised the water to be made warm—but it was too late.

The verdict in this case, however honestly given, undoubtedly offers a premium on the adoption of similar dangerous modes of treatment by weak or unprincipled people, for the sake of notoriety or gain, as the case may be; or, what is even more to be dreaded, out of a would-be benevolent motive, which shuts the eyes to the folly that is committed. A recent instance occurred in Scotland of the fatal consequences of amateur interference in Medical practice, where there was no suspicion of any other motive but an ill-devised benevolence. In this case, the patient had been affected for two or three weeks with acute rheumatism; several joints were involved; there was very considerable attendant fever, and latterly great frequency of the pulse. He was under the care of a regular Practitioner; nevertheless, an amateur Hydropathist, a person in a respectable line of life, altogether unconnected with the Medical Profession, contrived to get access to the patient, in the doctor's absence, and wrapped him in a wet sheet; the consequence of which was, his death in a few hours. The *post-mortem* examination proved, that the heart, the brain, and other internal organs, were free from disease; and, as death took place so shortly after the application of the sheet, little doubt could exist in the minds of Medical witnesses as to the immediate cause of that result. The amateur was not brought to trial, yet he suffered no slight penalty, having been apprehended, kept for some time in prison, and finally liberated on bail, without any assurance that he may not still be brought up to answer for his rashness. The only favourable point in this case is, that what he did was plainly with no purpose of gain. Though this case has never come before the public, we have reason to know, that the particulars given of it in the *Monthly Journal of Medical Science* are correct.

Were a computation made of the probable number of persons who yearly fall victims to benevolence of this sort, in all manner of forms, it could not but appear expedient for our legislators to consider how far it is practicable to provide a special Act, forbidding such interference, under appropriate penalties. For it seems hopeless to anticipate any conviction for offences of this kind in the common course of justice. In the mean time, the less that either this interference, dictated by a would-be benevolent motive, or the practice of unprincipled quackery, is made a subject of agitation by the members of the Medical Profession, the more likely is it that the evil will be taken up by the intelligent public. The members of the Medical Profession are regarded as interested parties, and they will not be listened to unless their testimony be confined to simple statements of fact, wholly unaccompanied by passionate comments. And it is especially necessary that medical witnesses should speak guardedly when their evidence is taken judicially in cases involving the charge of manslaughter by the ignorant application of powerful remedies.

Cholera is now decidedly on the decline here as in London. It is already upwards of a year since it broke out in Edinburgh, but during that period there has been an interregnum of several months. The revisitation dates from the beginning of August, and it has been by no means so severe as the disease was in the first months of its attack, and, altogether, very few persons beyond those of the very lowest condition have fallen victims to it here during the whole term of its prevalence. There has been a good deal of bowel-complaint of an ordinary character, and much choleraphobia, which last, in timid and nervous people, has been the source of considerable impairment of health.

On Tuesday the 9th current, Dr. Day was elected unanimously to the Chandos Professorship of Medicine in the University of St. Andrews. Professor Syme, it is expected, will be the new President of our College of Surgeons, Dr. J. A. Robertson declining to be re-elected on account of the state of his health.

IRELAND.

THE ALBERT UNIVERSITY. QUEEN'S COLLEGES IN IRELAND.

(From our Dublin Correspondent.)

We perceive, by the public prints, that it is in contemplation to establish a new University in Ireland, under the Chancellorship of Prince Albert. It is said, that the Senate of this proposed University will consist of sixteen or seventeen persons, to be appointed, in the first instance, by the Crown, and that no one belonging to the Queen's Colleges, with the exception of the three Presidents,

are to be permitted to take part in its proceedings. The duties of the Senate will be to regulate the curricula necessary for graduation in arts, medicine, and law; to appoint Examiners; and to hold sessions or commencements for the conferring of degrees. We presume, that the right of presentation to the junior and senior scholarships in the various Colleges will also be vested in this Senate. This new University is to have a house in Dublin, in which city all final examinations are to be held, and degrees are to be granted. It is further rumoured, and, indeed, this rumour has taken a semi official form, that the Irish executive has received a communication from the Prince Consort, expressing His Royal Highness's opinion, that such an arrangement as that above described is necessary, to prevent the new Colleges becoming nests of jobbery, corruption, and sectarianism.

Yet we feel a difficulty in reconciling these rumours with the very detailed and positive announcements proceeding from the Queen's Colleges (a). We can understand that the regulation of the hours of lecture, the amount of fees, and other matters connected with the administration of the new Colleges, should be legitimately the business of the Presidents and Vice-presidents of those Institutions; but, if these Colleges do not possess the power of conferring degrees,—that power being destined for a fourth, and not yet existing corporation,—it is manifest that everything relating to those degrees must proceed from an authority essentially extra-collegiate. The Presidents and Vice-Presidents, in conclave assembled, have drawn up curricula, settled the amount of graduation fees, decided on the minimum course of reading necessary for matriculation; and, we suppose, that there can be no doubt that their regulations received the sanction of the Government previously to publication. We cannot believe that the Presidents and Vice-Presidents have wittingly assumed an authority unsanctioned by the Charters of the Colleges over which they preside; and have recklessly announced a programme of education, as definitive and positive, which is nevertheless liable to be modified to an unlimited extent, by the only body, which, according to the hypothesis, would have a right to its imitation. To entertain such a supposition would be to credit that the Presidents and Vice-Presidents had knowingly insulted, because usurping, by anticipation, the functions of that Royal University, under whose control the colleges which they represent are about to be placed; and to imagine that those gentlemen are capable of practising a delusive hoax on the students of the United Empire, by presenting a cheap and easy bill of fare, in the shape of a curriculum, which, they well know, is totally destitute of any real validity. We cannot suppose for a moment, that the gentlemen alluded to, for the mere purpose of swelling the classes at the various Colleges, would be guilty of an act of such mockery and delusion; nor can we attribute the wickedness and folly of sanctioning it to the Government.

The fact, we believe, is, that some very gross blundering is being practised with respect to these new Colleges. We consider it to have been a great blunder to attempt converting these Colleges into Medical Schools, for which they are totally unfitted, from the want of subjects for anatomical purposes, and of Hospitals for clinical instruction; and multiplying the number of Professors, has obliged such a reduction of their salaries, that few men of any eminence or reputation have thought it worth their while to accept situations to which such mean remuneration was attached.

Since writing the foregoing we have met with a document, purporting to be a "Minute passed by the Board of Queen's Colleges," from which it would appear, that the regulations under the title of the Statutes of the Queen's Colleges in Ireland, have not yet received the sanction of the Government. We subjoin this "Minute":—

"Queen's Colleges.

"*Minute Passed by the Board.*

"Resolved,—That a Copy of the Statutes of the Queen's Colleges, now finally amended, be forwarded to His Excellency the Lord-Lieutenant.

"That the Board of Colleges avail themselves of this occasion to express to the Lord-Lieutenant their most sincere and respectful thanks for the gracious confidence with which he has honoured them throughout their protracted deliberations; for the extraordinary labour to which His Excellency has so frequently subjected himself in considering the multiplied collegiate questions brought under his notice by the members of this Board and others; and for the uniform and cordial support he has extended to the Queen's Colleges.

"The Board would more particularly refer to the inestimable aid these Institutions have received from the manner in which the recent selection of Professors has been made by his Excellency; from the patience and sagacity with which the claims of so many applicants have been investigated, and from the impartial justice which, in so large a number of appointments, has regarded only the merit of the candidate.

"The Board have seen, with grateful satisfaction, that all considerations of political patronage and personal favour have given way before the determination to confide every department to the man best qualified to fill it; that the Queen's Colleges have thus been placed in the foremost rank of Educational Establishments, and have already obtained that public confidence so essential to their success.

"The Board beg leave to express their confident belief, that the eminent men with whom the Colleges are provided, will enable them to fulfil the benevolent end for which they were founded; and that the speedy diffusion of a sound and useful education among the higher and middle classes of her people will not be the least of the advantages which the country will have derived from the administration of the Earl of Clarendon."

(a) The publication of the Regulations of the Queen's Colleges has been postponed this week from a great press of matter.

Complaints having reached us of the irregular delivery of the Medical Times *in the country by the Booksellers and Newsmen, we state, for the information of our readers, that this Journal is always published early on Friday afternoon, so that it may reach the Provinces by post on Saturday morning.*

Correspondents are requested to address their Communications to "The Editor of the Medical Times, 147, *Strand."*

TO SUBSCRIBERS.

New Subscribers will oblige by forwarding their Names direct to the Office, 147, *Strand, or to the News Agents or Booksellers. All Post-office Orders should be made payable to the Publishers,* Wm. S. Orr and Co.

THE MEDICAL TIMES.

SATURDAY, OCTOBER 20, 1849.

The appearance lately in our columns of the Introductory Lectures delivered at two of the largest Medical Schools in the Metropolis, has recalled to mind our Articles on Rationalism and Empiricism. In writing these Articles it was our endeavour, as it appears to have been the endeavour of Professor Walshe, to indicate the true foundation on which the science of Pathology is built, and to point to the method by which the fabric, based on that foundation, might be securely raised. The extreme importance of the subject—the erroneous opinions which have prevailed concerning it—the doubts which have been expressed even in high quarters, as to our right to claim for this branch of medicine the rank and title of a science, induce us now to recur to the topic.

The argument which Dr. Walshe(a) has presented to us may be thus expressed. All sciences are formed by the observation of individual phenomena—by the discovery of the mode of succession of these phenomena—and by the foundation, through induction, of the laws which govern them. As each science is merely distinguished from another science by the speciality of the phenomena on which it is built, if it can be shown that the phenomena, which are the subject-matter of any inquiry, are of a special and distinct character, are different from those whose observation, collocation, and classification form other sciences, then there appears to be no reason why the term science should not be conceded to the aggregate of these special and peculiar phenomena.

Now, Dr. Walshe affirms, that the phenomena of Pathology *are* special and distinct—that they arise out of, and indicate a substratum, which is identical with no other in the whole system of organized life—that they are to be known only by complying with the single condition on which human knowledge is possible, viz., by observation; and that the attempt to determine their existence, much less to explain their nature, by extending to them the observations, or by applying to them, without modification, the laws, which have been deduced from any other series of phenomena, however closely allied to them such phenomena may be, is manifestly illogical, and, indeed, impossible.

The correctness of this view is so evident, that it appears strange it should ever have been doubted. It is no doubt true, that the phenomena we are called upon to note at the bedside of the sick, have their analogies and similitudes in the phenomena which we may note in a perfectly healthy person. But that the two series of phenomena are not the *same*, are not *identical*, is evident from this fact, that, in disease, certain additions are made to the normal processes of life—certain elements are thrown in, whose mutual action and re-action on each other, and on the elements with which they intermingle, *must* be different from those processes; and, by the very law of human knowledge which compels us to observe, cannot be foretold or predicated by any acquaintance, however perfect, of what had occurred previous to the introduction of those foreign elements. Evidently it would be as impossible for the most accomplished Physiologist to tell us, *à priori*, what would be the result of throwing in among the normal elements of the body such an agent as the virus of small-pox, as it would be for the chemist to tell, previous to observation, what would be the effect of adding sulphuric acid to a barytic solution. This first and fundamental position is put forth, by Dr. Walshe, with great force, and with a certain vehemence, as if he knew the importance of vindicating earnestly the claims of Pathology to the rank of an inductive science.

But yet the great question of the day remains behind. What exact relation, then, do the cognate sciences, and especially Physiology,

(a) The Lecture of Dr. Walshe has been published separately, by Messrs. Orr and Co., Paternoster-row.

bear to Pathology?—what light will they throw on Pathology?—and to what extent will they aid us in the unraveling of this complex web of life which physical and vital forces so inextricably interweave?

The answer to this question is, to a certain point, determined without difficulty. Physiology assists in the study of Pathology in various ways. It supplies, first, the necessary standard of comparison. We must know the normal before we can perfectly indicate the abnormal; the one is indispensable to the comprehension of the other, although it is not this other. Secondly, Physiology, and the cognate sciences generally, aid Pathology, by affording to it the appliances and means by which its phenomena may be recognised. Physiological and chemical *phenomena* cannot, it is true, *suggest* to us pathological phenomena; but physiological and chemical *manipulations* are often the only means by which we can *detect* these phenomena. In proportion as Physiology and Chemistry perfect their own methods,—in proportion to the clearness of the microscope, the fineness of the balance,—will be the minuteness and the accuracy of the process by which one pathological phenomenon is defined and isolated from another. Thirdly, these collateral sciences may aid pathological inquiry by the suggestions concerning abnormal conditions which the discovery of the normal laws may give us. These powers and functions of Physiology, in respect of Pathology, have been emphatically recognised by Dr. Walshe.

But beyond this, still, does not Physiology bear to Pathology a deeper relation? Is it not necessary for the explanation, for the due arrangement, for the systematic grouping of pathological facts, that the laws which rule the analogous series of physiological facts shall be known? Is not the inquiry into Physiological laws, the simple, the primary, the necessarily antecedent problem which must be solved before we can determine the connexion of those more complex and intricate phenomena, which are, as it were, in a certain sense, aberrant and wandering physiological conditions? In the same way, as it is necessary to decide the anatomy of the normal tissue, before we can perfectly determine the anatomy of the abnormal tissue; so, is it not necessary to determine the nexus, and to fix the classification of physiological phenomena, before we can safely attempt to bind up pathological phenomena in a similar arrangement? In a certain sense, is not Physiology a *basis* to Pathology, or, at least, to the highest and most perfect parts of it? It is plain, that, even here, we do not abandon our groundwork of observation. Pathological phenomena must ever be observed, can never be divined; but when observed, can we wring their most hidden consequences from them without a knowledge of the normal conditions from which they are an offshoot and a deviation?

It is thus, as we formerly took occasion to point out, that as Pathology and Physiology expand, the radii passing from the proper and independent centres of each, impinge on each other and intermix. By this mutual impression, each imparts to the other something of its own virtue, illuminates the other with its own light; Physiology suggests the laws which may govern Pathology, and Pathology by the very aberrations from physiological laws which it exhibits, illustrates the truth of these laws, or points out the errors which infect them. The extent to which this can, as yet, be done, is a most interesting topic, and we would gladly hear the eloquent Professor of University College enlarge on this head more fully than his short lecture hour could permit.

The excellent Oration of Professor Farre(a) discusses some of the causes which have retarded the advance of medical science. As connected with the employment of the inductive method, Dr. Farre points out the extreme intricacy of the phenomena,—their rarity,—the difficulty of witnessing them except in portions,—the interference of vital with physical laws, of animate with inanimate matter, as some of the chief causes inherent in the subject itself, which have delayed its elucidation. But we cannot agree with Dr. Farre, that these difficulties which certainly impede the application of the inductive method, should induce us to apply it "*less strictly*." On the contrary, in proportion to the intricacy of the subject, should be the vigour of the method. Not *less* strictly, but *more* strictly should we make our researches when the subject baffles us. Is the labyrinth darker and more bewildering? the firmer must we hold to the clue which alone can track its devious paths.

And that it is by the use of the inductive method, as taught by Lord Bacon, that the science of Pathology, as all human sciences, is to be advanced, no one, who reflects sufficiently on this subject, can for a moment doubt. It is, indeed, a matter for great rejoicing that this opinion is gradually gaining ground; and that the modern British school of Pathology promises to be as laborious in observation, as prudent in induction, and as cautious in conjecture, as become the earnest followers of the great master of modern philosophy.

(a) Since published by Mr. Churchill, Princes-street.

THE COLLEGE OF SURGEONS IN DANGER—PROSPECT OF A REVIVAL OF DIVINE DOCTORS.

In this age of wonders, we are hardly surprised at any discoveries that are made. The spirit of investigation appears not to be confined to the Medical Profession; for barristers, without the aid of the microscope, sometimes find out, in legal documents which the wisdom of our forefathers have bequeathed us, forensic curiosities. The sharp-sightedness of lawyers has always been proverbial; and the exact meaning of a Parliamentary enactment is never known till it has been subjected to a lengthened and searching scrutiny from those who are technically called "gentlemen of the long robe." Laws, therefore, which were intended to be specific and decisive, have become, by the learned ingenuity of their expounders, the most uncertain of all uncertainties. By means of forensic eloquence, astonishing metamorphoses have been produced. Criminals, treble-dyed in guilt, have been made legally to appear immaculately pure; the rigid deductions of science have been turned into falsehoods; and the best titles to property or privileges have been proved to be worthless.

It has been generally thought, that the Charter of the Royal College of Surgeons of England conferred upon its members certain privileges; and amongst them, that of recovering any reasonable sum for attendance upon a surgical case: the acumen of a young lawyer of the Middle Temple, however, has recently detected such a flaw in the Royal document which gave the Corporation of Lincoln's-inn-fields existence, as precludes its members from obtaining fees from patients, with broken bones or dislocated joints, indisposed to pay.

Mr. Howard Fellows is the learned barrister who has made this notable discovery; and he has given it as his opinion, that members of the College are not *legal* surgeons. First, because they have not been examined by the Bishop of London and the Dean of St. Pauls; and 2nd, because they are not licensed under the Act of George II. We extract from a Contemporary a case and an opinion.

"CASE.

"Messrs. W. and S. are General Practitioners, having passed the College and Apothecaries' Hall, and having the usual license from the latter body. They have been professionally employed by Mr. R. to set a broken leg, which they did, and afterwards applied for their charges, but the claim was resisted, because as R. in a letter to them says—'you know you are not licensed as surgeons, and therefore cannot make me pay; nor will I do so unless you make the above deductions from your bill, which, as it stands, I consider unreasonable.' Messrs. W. and S. thinking their charges fair, have issued a writ for the amount; but before incurring further expense wish to know whether any license is necessary, because if it is, there is no doubt but that R. would take advantage of the want of one. Messrs. W. and S. have never heard of any license for a surgeon, or that any one who had passed the examinations was not fully entitled to practise. It is assumed that the Apothecaries' license has nothing to do with surgery, and that they could, at any rate, recover for the medicines supplied during the process of the cure."

"OPINION.

"It is not stated when the attendance took place; but, as will be presently seen, that does not make much difference. At common law no license of any kind was necessary for a surgeon, and, consequently, ignorant persons were in the habit of practising. To prevent this it was enacted by 3 Hen. VIII. c. xi. sec. 1, that 'no person within the city of London, nor within seven miles of the same,' should practise surgery except he be admitted by the Bishop of London, or Dean of Paul's; and by sec. 2, 'no person out of the said city and precincts of seven miles' shall so practise unless he be approved by the Bishop of the diocese. There are, however, two exceptions to this rule. The first (within which the plaintiffs do not come) is contained in the 34th and 35th Henry VIII. c. viii, which allows any one to practise gratuitously without a license; and the second in the 18th Geo. II. c. xv., sec. 8, which authorises persons licensed by the Company of Surgeons to practise 'throughout all and every His Majesty's dominions.' The examination by the College (which is a different body from the Company) of Surgeons is merely voluntary, and as not passing it works no disability, so passing it confers no legal rights. Unless, therefore, the plaintiffs are licensed under the Acts of Henry or George, they cannot recover (Cope v. Rowlands, 2 M. and W. 149, where it was held that an unlicensed broker could not sue for his commission), and must therefore take what the defendant offers, as by bringing their action they would probably lose all: they clearly could not compel payment, even for the medicines, for they were used as ancillary to a surgical case (Alison v. Haydon, 4 Bing. 619), and not supplied by the plaintiffs as apothecaries, but as surgeons. "THOS. HOWARD FELLOWS.

"1, King's-bench-walk, Temple,
Sept. 6, 1849."

We have, in consequence of this opinion, considered it necessary to examine the several documents referred to, and we have also consulted some of the authorities of the College of

Surgeons intimately acquainted with the events which led to the granting of the Charter by Geo. III.

There can be no doubt that the Bishops formerly exercised the privilege of examining and licensing Practitioners both in Medicine and Surgery; and that, while Henry VIII. took from the Episcopal bench the authority to make *Physicians*, he did not interfere with the Bishops' rights as regards *Surgeons*. The Act of Geo. II., however, (in 1745,) not only brought into existence the Corporation of Surgeons; but gave it authority to examine persons; and passing this examination they became entitled to practise, without let or hindrance, the art and science of surgery throughout all His Majesty's dominions, notwithstanding any law or custom to the contrary. It is evident, that by this Act, the power of the Bishops to license Practitioners in Surgery was taken away, and so long as the Corporation existed, that power could not be recovered. But, Mr. Howard Fellows' opinion is based upon the supposition, that the Corporation of Surgeons is defunct; and that the present College never having had an Act of Parliament passed in its favour, is a different Institution, and, therefore, cannot enjoy the same privileges as that which George the Second founded.

A curious circumstance at the close of the last century led to the dissolution of the old Corporation. The Act of Parliament required certain duties to be performed on a certain day, by certain of the Corporation officers. When the day arrived for the meeting of these officers, one was laid up with an attack of gout, and another, we believe, was labouring under paralysis. There was, in consequence, no meeting, and the Corporation was generally considered as having become defunct.

It was, therefore, deemed necessary that a new Charter should be issued; and, in the year 1800, one was granted "to James Earle and unto all the Members of the said late Company or Corporation of Masters, Governors, and Commonalty of the art and science of Surgeons of London, having been admitted and approved Surgeons within the rules of the said Company." It is evident, therefore, from this passage, that it was the intention of the then Government to revive in the College the defunct Corporation of Surgeons, and to invest the former, as far as possible, with all the privileges of the latter. Upon this point, the Charter of George III. says, "And it is our further will and pleasure: and we do hereby, so far as we lawfully can or may grant and ordain, that the said Royal College of Surgeons hereby incorporated shall and may exercise and enjoy all and singular other the gifts, grants, liberties, privileges, communities, and possessions real and personal, and whatsoever and wheresoever, herein before mentioned, or by any Act or Acts of Parliament, or by any Letters Patent, of our Royal predecessors, Kings and Queens of England; given, granted, and confirmed unto, or otherwise lawfully acquired by, and belonging to the said late Master, Governors, and Commonalty of the art and science of Surgeons, or any of them, and not hereby altered, taken away, changed or abridged, made void, or annulled." If this Charter have any virtue in it, then we conceive it not only gives Members of the College a legal right to practise, but a legal power to receive a reasonable sum for their attendance upon surgical cases.

The force of Mr. Fellows' argument rests upon the supposition, that a Royal Charter cannot confer the same privileges upon a new Corporation as were enjoyed by one defunct, although the new Corporation may be composed of the same individuals, and may be established for the same purposes as the old one. Hence he cites the case of the unlicensed broker, and views the Members of the College in the same predicament, not having gone before the Right Reverend Bench of Bishops to obtain licenses to practise surgery.

The power of the College having been questioned, doubtless it will soon be tried in a court of law; but, whether this be the case or not, we see additional necessity for a speedy settlement of the question of Medical reform. A pretty thing, forsooth, for Surgeons to be placed under episcopal authority—and for the country to be threatened with a new race of Divine Doctors! Mr. Howard Fellows is evidently a sharp-sighted lawyer; he has emerged from obscurity, and it may be, has taken the first step towards the woolsack!

THE CHANDOS PROFESSORSHIP AT ST. ANDREW'S.

Dr. Day has received the appointment of Chandos Professor in the University of St. Andrews, lately become vacant by the decease of the lamented Dr. John Reid. We do not know of any public appointment which has been lately made, that has given us more sincere gratification. Not simply that we are pleased at seeing a man so universally esteemed as Dr. Day appointed to this chair, but also because such an appointment is an indication that the Medical Corporations are beginning to drop their exclusiveness, to lessen their restrictions, and to choose the best person for the vacant post. It would, indeed, have been tantamount to a setting aside of all scientific claims, if the Editor and illustrator of Simon and Vogel, the translator of Rokitansky and of the Cavendish Memoirs, the well-known Chemical teacher, who has, perhaps, done more to make his countrymen acquainted with the application of Chemistry to Pathology than any other man, had been unsuccessful. It would have been indeed discouraging if these eminent services had been counteracted by local interest, or disregarded by party or national feelings. As our readers are aware, several candidates opposed Dr. Day, but universal opinion stamped him as best entitled to the Chair.

We congratulate the authorities of St. Andrews on the confirmation which their election gives to general opinion.

THE COLLEGE OF PHYSICIANS AND THE "FUNGUS THEORY" OF CHOLERA.

We have been informed, on undoubted authority, that a Report is to be published during the ensuing week by the Cholera Committee of the College of Physicians, containing observations which throw considerable discredit on, if they do not entirely put aside, the hypothesis that Cholera depends on the presence in the intestinal canal of the so-called "Cholera fungus." We hope to be able to obtain in time for our next Number, at least the most important facts contained in the Report.

REVIEWS.

1. *Malignant Cholera, its Mode of Propagation and its Prevention.* By Wm. Budd, M.D., Physician to the Bristol Infirmary. 1849. Pp. 30.
2. *On the Mode of Communication of Cholera.* By John Snow, M.D., Lond. 1849. Pp. 31.

In the pamphlet which heads our review, Dr. Budd has presented us with a repetition and an amplification of his views on Cholera, already made known in the letter which appeared in the columns of the *Times* newspaper. Many portions of the pamphlet are copied from the letter; other portions are new, and are brought forward in confirmation or in explanation of the more doubtful points. We need scarcely remind our readers of the general tenour of Dr. Budd's opinions. It will be remembered that Dr. Budd adopts unequivocally the view that Cholera is the result of the rapid development within the alimentary canal of a species of fungus; that this fungus finds its way into the canal only by swallowing, and that after multiplication in the canal and discharge therefrom, it is disseminated through the medium of the air, or by adhering to articles of food, or by finding its way into the water, which may subsequently be used for drinking.

To these views we took occasion to object in a late Number, that, however true they might be, the basis of facts on which they were founded was by no means so broad and so comprehensive as to warrant Dr. Budd's conclusions, or to lead us to do more than consider his opinions as an ingenious hypothesis, which might or might not be more or less correct. The perusal of Dr. Budd's pamphlet has not induced us to change our opinion, and we shall not scruple to express our conviction of the doubtfulness of much of Dr. Budd's reasoning.

In the first six or eight pages of his pamphlet, Dr. Budd describes the general appearance of the organic corpuscle, which has been called "annular body" by Dr. Brittan, "Cholera cell" by Dr. Swayne, "loimodic cell" by the contributor of some able articles on Cholera to the daily *Times*, and "Cholera fungus" by Dr. Budd himself. This description need not detain us, as it is not different from that already given in our columns. After stating that he has invariably found these "organisms" in the sediments of the rice-water discharges, and especially in those of a dirty white colour, (which, by the way we may remark, is somewhat remarkable, seeing that the pure white sediments, in which these organic corpuscles are said to be smaller and less abundant, are more common in the intensest cases,) Dr. Budd proceeds to make his first assertion, viz., that the "organism" is in some way essentially related to malignant Cholera. He supports this by the following considerations:—

"1. By the characteristics of the thing itself, which, by showing it to be possessed of a complex organisation, having a definite mode of development, a specific form and spontaneous power of growth and multiplication, stamp it at once as being of distinct species.

"2. By its constant presence in cases of Cholera, and its absence (with a few casual exceptions, in which a small number of stray bodies of similar character are found) in other diseases.

"3. By its presence in the discharges in such infinite numbers.

"This last consideration, when taken together with the two former, is very striking. For assuming the thing itself to be, what it is here asserted to be, a definite living organism, and therefore of extrinsic origin, it becomes impossible to conceive that its presence in such countless numbers in the 'rice water' can be a matter of chance, a mere incident, an epiphenomenon, or anything in fact short of an essential character of the disease; and if essential,

many other considerations are at hand to declare that the relation thus inferred to exist, can only be one of cause and effect." (P. 8.)

It appears to us sufficient merely to read this passage, in order to detect the numerous assumptions made in it. The great assumption, on which hinges all the rest, is the constant presence of these organisms in cholera evacuations, and their absence in all other diseases. But can either of these propositions be, for a moment, considered as established? How many cholera evacuations, how many discharges in other diseases, have been microscopically studied? Can Dr. Budd himself supply the hiatus in direct observation which is presumed to exist? If he cannot, he ought not to venture on an assertion of such importance. In the fluid stools of typhoid fever, for example,—in the loose, dark evacuations of bilious diarrhœa,—not to speak of other diseases,—there is so great a variety of microscopic cell-forms, which have as yet received no full description, that we have no hesitation in refusing to allow any value to two or three negative observations. But even if those bodies are constantly present in cholera discharges, and are absent in all other cases, we are still indisposed to admit the truth of Dr. Budd's other assumptions, that because those bodies are of complex organization, and because they exist in great numbers, therefore they stand in the relation of cause to cholera. These bodies are not more complex than the torulæ which form in fermentation; they are not more numerous; they are not more constant; and yet the yeast-plant is, as we formerly remarked, merely an index of the profound changes it accompanies, and by no means their cause. And we may observe, that the rapidity with which these low forms of life are called into being in their appropriate nidus is quite wonderful; the exudation which in the night forms on the mucous membrane of the mouth of the patient with typhoid fever, in the morning may be found pierced in all directions by the branching cells of a cryptogamic plant, and in the yellow matrix of Favus the consecutive fungus spreads not less rapidly into development. Against such an error as that of confounding a consequence with a cause, we cannot be too careful, if we are dealing with these organic forms, the facility of whose birth is paralleled only by the rapidity of their decay.

But Dr. Budd adduces some other considerations in support of his hypothesis.

As these organisms exist in myriads in the cholera discharges, and as they are not introduced in such numbers, they must be developed within the intestine. In such development, says Dr. Budd, they must require nutriment; and in what other source, except in the fluids of the body at large, are we to find the materials for their increase?

"I need scarcely say," continues Dr. Budd, "to those who have watched the course of inquiry on this subject, that the drain of fluid which is here implied is exactly what chemical analysis has shown to be the cause of all the phenomena comprised in the state of collapse."—P. 9.

Here, it appears to us, is another assumption. Can it be for a moment maintained, that chemical analyses have yet been made in sufficient number to establish this most important doctrine, that the collapsed symptoms of cholera are in the ratio of the discharges, and of the increased spissitude of the blood. So far, also, from its being the case that this doctrine has been developed by the progress of inquiry, it was positively the original view espoused by O'Shaughnessy, though qualified by him in such a manner as almost to be surrendered.

Dr. Budd further attempts to strengthen his position by the additional considerations which he seems to consider proved, viz., that the fungi are constantly found in the air and water of infected districts.

Up to this point the argument stands thus:—

It is *assumed*—

1. That the peculiar bodies are fungi.
2. That they exist constantly in cholera discharges, and not elsewhere.
3. That by reason of their complex organization, and of their number, (taken with their invariable presence,) they must be the cause of cholera.
4. That as the fungi are introduced in small numbers, and are voided in myriads, they must be increased within the body, at the expense of that body's fluid; the drain of fluid thus resulting produces all the other symptoms.
5. That the constant presence of the fungi in the air and water of infected districts affords evidence confirmatory of these inferences.

Now, each of these propositions is individually doubtful. Can the aggregate of them give certainty? Each by itself is, and must, for some time, be intrinsically weak. Can the combination of them give strength? Is it possible that the mere addition of probability to probability, or possibility to possibility, can evolve a demonstration; that the whole can possess qualities which are not furnished to it by its parts? Can that, which of itself, has no solidity, be reared aloft by props which themselves have no firm basis, but lend to each other a vague and unstable support? True; a certain probability may in this way be given: an hypothesis may be formed, a mode of investigation may be indicated, but immaturity and uncertainty must characterise the opinion until experience has stamped it with its indelible sign of truth.

Another opinion entertained by Dr. Budd is not absolutely necessary to the integrity of his hypothesis, but it is to the treatment founded upon it. This is the opinion, that the human intestine is the sole breeding place of the fungi.

Stripped of the reasoning, often ingenious but rarely sound, with which Dr. Budd surrounds his argument, we find his naked positions to take this form:—

The cholera fungi breed *only* in the human intestine—

1. Because they certainly *in part* breed there.
2. Because they are larger and more developed there.
3. Because they have not been discovered elsewhere, with characters indicating a process of development.
4. Because the mode of diffusion of cholera accords with such a mode of propagation.
5. Because such a mode of propagation is sufficient to account for the diffusion of the disease.
6. Because the lower animals are not attacked.

The two first positions prove nothing; the third is founded on insufficient evidence; the fourth and fifth give us a good example of reasoning in a circle; and the sixth is erroneous.

Dr. Budd then passes on to consider the mode of diffusion of cholera. He here adopts, without reserve, the opinions of Dr. Snow, which, however, like his own, can be regarded only as suggestive, and not as absolutely proved.

Dr. Snow believes that cholera is contagious in the true sense of the word,—viz., that a sick person can communicate the disease to a healthy person; but this does not occur, as usually supposed, through the medium of the atmosphere, but through the instrumentality of water, into which the evacuations of cholera, which Dr. Snow supposes to contain the specific cause, have somehow or other been introduced. Dr. Snow was led to this view by the consideration, that the early symptoms of cholera did not resemble those consequent on the introduction of febrile poisons, in which the blood is first affected, but seems to result from an immediate impression on the mucous membrane in the canal, on which all the other symptoms were consecutive. Dr. Snow was then naturally led to infer, that the active cause, which appeared to be taken into the alimentary canal, might be discharged thence, and received by swallowing into another canal, on which it might make a like impression. Carrying out this notion, Dr. Snow surmised that the discharges of the sick, passing into the sewers, might possibly become mixed with the drinking water, and be in this way communicated. As evidence in favour of this he brings forward two cases, viz., Surrey-buildings, Horsleydown, and Albion-terrace, Wandsworth-road, in both of which places there has been a local attack of cholera, while in both places the water appears to have become contaminated by sewage matter.

Dr. Snow appears to have finally arrived at his conclusion, chiefly by the principle of exclusion, viz., that in these two localities the only circumstances common to both were the existence of this contaminated water, and the non-existence of cholera in the immediate neighbourhood where the water was not in use.

We shall have occasion to allude again to these views of Dr. Snow, which we have no hesitation in considering ingenious and well worthy of attention. We do not think it unlikely that this may be one mode of communication of cholera, although exception might be taken to much of Dr. Snow's evidence. But we have no hesitation in stating that it cannot include all the phenomena of cholera, and that the disease must spread in other ways.

Both Drs. Budd and Snow have, we think, considered their own hypotheses in too one-sided a manner. They have applied their speculations to two or three examples; let them apply them to the multitude of facts which have been recorded concerning cholera, and see how these can be explained. The facts, which may be contrary to their views, are very lightly passed over by both these gentlemen.

REPORTS OF SOCIETIES.

WESTMINSTER MEDICAL SOCIETY.

October 6, 1849.

FRANCIS HIRD, Esq., President.

Dr. Webster read a paper, entitled "Observations on the Health of the Metropolis during the Last Six Months, more especially in reference to the Recent Epidemic Cholera." The Author showed that the mortality in the quarter up to Midsummer, was 1¼ per cent. less than in the preceding year, although cholera and diarrhœa had destroyed many persons, the diminution resulting principally from the cessation of scarlet fever; while the mortality in the second portion of the six months has never been exceeded since the great plague in 1665, the mortality being double that of the same quarter in 1848. Other diseases, however, had been less fatal, the principal mortality being from cholera and diarrhœa. In the low grounds on the south bank of the Thames, one-half the deaths had occurred, being treble that on the northern side; the proportion being, in Lambeth, 1 in 91 inhabitants; in St. George's, Southwark, 1 in 64; in Bermondsey, 1 in 56; on the northern side the average being 1 in 252. Bethlem Hospital, Bridewell prison, Coldbath-fields' Prison, and the Regiment in London, had entirely escaped. More females than males had died; and as regards age, more than half the deaths occurred in middle life, nearly a quarter in childhood, and only one-sixth in old age. The author then referred at some length to the various

local and personal causes, as well as the state of the weather likely to produce or aggravate the disease. Diarrhœa had prevailed in Bethlem, but was treated instantly and arrested.

Mr. Harding reported the immunity of St. Pancras Workhouse, and observed, that the water used there is drawn from an artesian well.

Dr. Cormack considered that observations upon cholera, over an extended surface of country, showed considerable analogy to ague in its prevalence more or less in certain localities. He referred to Comparetti's account of persons dying generally in the cold stage of the ague then prevailing, also to Torti's treatment in 1680 of such cases by cinchona, and to Sydenham's account of the medical constitution of the air, as developing intermittent or remittent fever, or cholera.

Mr. Streeter had, with Mr. Quekett, examined cholera urine, and found organic granules like those described by Mr. Brittan. He thought the collapse was owing to the absorption of these into the blood.

Dr. Lankester considered Mr. Brittan's particles to be epithelial cells, and observed, that the fungi must pass through the blood to get into the urine, which militated strongly against the theory of Mr. Brittan, as did likewise the suddenness of the attacks.

Mr. Busk, an excellent microscopist, had failed to recognise as fungi these bodies after a most careful search.

The discussion was then adjourned.

OCTOBER 13.

Francis Hird, Esq., President.

Dr. Snow then read a paper, on

THE PATHOLOGY AND MODE OF COMMUNICATION IN CHOLERA.

He said, that he had been led, contrary to the usual opinion, to consider that the seat of cholera is, in the first instance, at least, confined to the alimentary canal, and that the disease is not occasioned by a poison in the blood; for in those diseases in which a morbid poison was absorbed into the blood, general symptoms of a febrile character always precede any local affections which may arise, which is not the case in cholera. In all the cases he had witnessed, the loss of the watery part of the blood seemed sufficient to account for the collapse, and, in fact, all the general symptoms; and when cholera commenced gradually it could often be stopped, whilst yet, in the stage of diarrhœa, by remedies adapted to act merely on the bowels. This view of cholera had lately been confirmed by the discovery of certain microscopic bodies, believed to be of a vegetable character, in great abundance in the rice-water evacuations. An attentive examination of the history of cholera, as an epidemic, showed it to be communicated by means of human intercourse; and, although there were many facts which were opposed to the theory of its being contagious, in the same way with eruptive fevers, yet these facts would be found, in the sequel, to afford the strongest confirmation of the communication of the disease. Considering cholera, then, to be a local affection of the alimentary canal, and to be communicable, it was clear that it could only be conveyed from one patient to another by something which passed from the mucous membrane of one to that of the other, which it could only do by being swallowed; and, as the disease grows in a community by what it feeds upon, attacking a few persons in a town first, and then spreading to a greater number, it was evident that the cholera poison must multiply itself in the patient like every other morbid poison. The instances in which the cholera evacuations must be swallowed were sufficiently numerous to account for the spread of the malady, and it would be found to spread most where the facilities for this mode of communication of the disease were greatest. The bed linen nearly always becomes wetted with the evacuations, and as these were without colour or odour, the hands of persons waiting on the patients become soiled without their observing it, and unless they are extremely cleanly in their habits, and have opportunities for washing their hands before taking food, they would be liable to swallow a minute quantity of the excretion, and also leave some portion on the food which they handle or prepare, that has to be eaten by the rest of the family, who amongst the working classes often have to take their meals in the sick room; hence the thousands of instances amongst this class of the community of a case of cholera in one member of a family being followed by other cases, whilst medical men and other persons who merely visited the patient without partaking of food, generally escaped infection. One important means of the spread of cholera is by the water used for drinking and culinary purposes becoming contaminated by the cholera evacuations, either by their permeating the ground and entering wells, or by their running into rivers by way of drains and sewers. He enumerated several instances in which great fatality of cholera in particular places was connected with this kind of contamination of the water, and stated that the towns, such as Birmingham, Bath, Cheltenham, and Leicester, in which the Cholera has not spread to any extent, either in 1832 or the present year, were supplied with water quite untainted by drains and sewers. Dr. Wm. Budd had found the microscopic bodies before alluded to, in such drinking water of cholera districts as received the contents of sewers. In conclusion he stated several measures which he thought calculated to prevent the spread of Cholera. The chief of these were a scrupulous attention to cleanliness in those waiting on the sick, and the avoidance of water that receives the contents of drains or cesspools, or if this cannot be effected, to have the water well boiled before being used.

Dr. Swayne (of Bristol,) agreed with Dr. Snow, that the poison of cholera does not enter the blood, because the first stage or diarrhœa is so easily checked. He then related the circumstances of the discovery of his microscopic cells, and said that they were mostly found in the flocculent deposit in the dejecta; seldom in the fluid vomited. The cells are surrounded by a ring of projecting nodules; the cells in the air, found by Mr. Brittan, in the rooms in which persons had died of cholera, and also where they had sickened, bore much the same character, but were more broken. The cells resemble the smut of wheat, but are larger, and quite clear. The cells were not found in only four or five cases out of about fifty.

Dr. Ogier Ward said, that at Bilston collieries there are no wells, but the water pumped from the mines runs down the streets in ditches, which are enlarged here and there to serve as wells; hence the water is very foul. At Birmingham, the ground is not level, and the river, which receives the sewerage, is rendered so black as not to be drinkable.

Mr. Walsh said, that, at Bermondsey, the water commonly drank is rendered impure by the privies opening into it.

Dr. Willshire doubted the connexion so often referred to between diarrhœa and cholera.

Dr. Copland thought, that if the water contaminated by the burial-grounds was examined, Mr. Brittan's cells would be found in it. But this contamination had existed for years without producing cholera. It might, however, predispose to an attack. He quoted from his article on "Choleric Pestilence," that emanations from putrid masses assume the form of organised substances, and so propagate themselves.

Dr. A. P. Stewart observed, that the Commissioners sent to Warsaw in 1832, swallowed cholera evacuations in a concentrated form, yet none died from it. The fungus theory does not account for the terrific rapidity with which cholera spreads at different times. The susceptibility of persons to the disease bears no proportion to their exposure to the disease.

The discussion was again adjourned.

DR. TUCKER ON THE SALINE TREATMENT OF CHOLERA.

[To the Editor of the Medical Times.]

Sir,—As you seem desirous to receive communications upon the all-important subject of cholera, I am induced to give you, in general terms, a report of my trial of the saline treatment, recommended by Dr. Stevens, the only practice I adopted during the six weeks this disease prevailed in Sligo.

Even before trial, the saline treatment appeared to me the most simple and scientific; but, since I have had an opportunity of witnessing its effects, I feel convinced that it is the most efficacious and successful of any practice that is yet known. In every instance where the patient was put under treatment before collapse set in, the case did well, while many patients in the last stage, who appeared to be beyond all hope, recovered, under its use. Those few cases that terminated fatally were all in collapse before I had an opportunity of putting them under treatment. They were either persons of delicate and broken-down constitutions, or so poor that their friends had not the means to carry out the treatment. Small bleedings, blisters sprinkled with turpentine and applied over the heart, sinapisms to other parts, and the internal use of salines conjoined, were remarkably successful. Not a single case proved fatal from consecutive fever. In no instance did I attempt to check vomiting and diarrhœa by opiates and astringents. I observed, that when these symptoms were violent, the patients did well; while those cases in which little vomiting and diarrhœa occurred were the worst.

Now, if these symptoms be, as I believe, Nature's efforts to throw off the poison, it is clear, that to check that effort is to destroy all hope of the patient's recovery. The duty of the practitioner is to aid, not check the *vis medicatrix naturæ*. In accordance with this view, so far from attempting to restrain the action of the bowels, I would, in addition, if possible, excite the action of the skin and kidneys, so that all the outlets of the body might combine in the expulsion of the poison.

To check vomiting and purging, is, as Dr. Stevens states, "to lock up the poison in the body, so that fever and death is the consequence of it." A medical student who was employed in 1832, at Paris, to treat cholera, wrote thus:—"I first cured them of the bowel complaint, and then they got fever. I cured them of the fever, but still they died, and no thanks to me."

The Practitioners of the Pym and Barry school require to reconsider the first principles of medicine. They must regard cholera as a struggle between two powers,—the poison of the malady forcing the patient into collapse, by its sedative and depressing influence upon the blood, and, through it, upon the nervous and circulating systems; and, on the other hand, the vital power of the patient endeavouring to expel it by means of the excretions. This contest for life or death induces a variety of effects termed symptoms, which are not to be treated separately, but their cause must be removed, and for this purpose the treatment recommended by Dr. Stevens seems the most appropriate. He advises extreme attention to cleanliness and pure air; in this way the remote cause of the disease is removed, while by the use of salines, the poison—the proximate cause of the disease—is driven from the blood. If we consider the altered condition of the blood in cholera, robbed of its water and saline materials so essential to life, and surcharged with those poisonous, carbonaceous, and nitrogenous matters that in health are thrown off by the lungs, liver, skin, kidneys, bowels, &c., we shall clearly see how necessary it is to direct all our energies to restore its healthy condition, and to re-supply it with materials essential for its vitality and vigour. Of all the remedies recommended for cholera, Dr. Stevens' is alone calculated to restore to the blood its lost materials; for, by it not only are the lost salts and water re-supplied, but, by means of the chlorate of potash, its arterial condition is more or less provided for, as every three grains of this salt will yield four cubic inches of oxygen gas, the quantity inspired at each respiration. It is the want of this all-important vital element, oxygen—or, according to Dr. Stevens, the vital electricity contained in it—that causes asphyxia, and hurries off the victim of cholera in a few hours. It is absurd to suppose that opium, alcohol, chloroform, or any form of stimulant, astringent, mercurial, or other medicine, (save salines,) can remove this state of disease. Opium may mitigate the pains and pangs of the dying—it may be, what a fanciful writer says of it, "Peace of mind-portable ecstasies pent up in pint bottles, and purchased for pence"; but, in cholera, opium will neither remove the poison from the body, nor restore to the blood one particle of its lost saline or electric materials. But, if Practitioners would recollect that alcoholic stimulants are soon followed by greater depression, they would see the inutility of administering them in the cold stage of cholera, when the vital and chemical functions of respiration, oxygenation of blood, and calorification, are suspended. From their elementary constitution, I regard them as worse than useless—a positive evil, calculated to increase the excessively carbonaceous condition of the blood; for the same reason, ether and chloroform, and ammonia, are all-powerful for mischief in proportion to the absence of oxygen in their composition. Oxygen (not alcohol) is the stimulant nature requires, and calls for, by insatiable desire for cold water, which contains 8-9ths of this vital element. Dr. Stevens maintains, that not only heat, but vital electricity is derived from the oxygen of the air we breathe. Now, as our exist-

ence depends upon two forces, the chemical and the vital, which perform two functions, calorification and nutrition, producing two results, waste and supply, and as oxygen is the chemical force whose function is calorification, by means of which not only the old materials of the body, but also morbid matters, are removed from the blood, we can easily understand how necessary it is to keep up a constant supply of that vital element. Liebig states that without the aid of oxygen, morbid matters cannot be destroyed or removed from the system; that in febrile diseases the blood by reaction, *i. e.*, fever, becomes a means of cure, as a carrier of oxygen. Our object in cholera should be to establish reaction by means of oxygen: our only hope of effecting this in the cold or collapse stage is through the stomach, by means of the chlorate of potash and other salts. I am unable to understand how benefit can be expected in cholera from mercurial treatment, when I consider the nature of the disease—a toxæmic state or poison of the blood—and that the therapeutic action of mercury in inflammatory diseases is to kill a portion of the blood, to break down new and morbid structures, to diminish the function of sanguification, and to reduce animal heat to its normal standard. To be efficacious in cholera, it should have effects quite opposite to those I have just mentioned. The deadly influence of mercurial vapour upon the lower animals demonstrates its poisonous power upon animal life. Mercury is not one of the natural ingredients in the vital currents, neither can it restore to the blood any of its lost materials, which is the important point to be considered in the treatment of cholera. I am, therefore, from the foregoing reasons, convinced that the saline treatment of Dr. Stevens is the proper practice to be pursued, as it appears to be the only one that has anything like rational principle or real success in practice to support it. The Goverment ought to inquire into the real merits of the saline treatment and appoint Commissioners to report upon the various modes of practice in cholera. In 1845, Commissioners were appointed in Ireland to report upon the nature of the potato rot, and surely the cholera may well call for a similar investigation; and whatever materialists may say on this subject, a man is of more value than a potato, or any other material thing in this world.

I remain, Sir, your obedient servant,
J. Tucker, M.D., M.R.C.S., Medical Attendant,
St. John's Dispensary, Sligo.
October, 1849.

LORD *versus* WAKLEY—REFUSAL OF A FEE TO A MEDICAL WITNESS BY A CORONER.

[To the Editor of the Medical Times.]

Sir,—Your last number had a leader on Coroners' Inquests, and the Law relating to Medical Witnesses. *Apropos* to the subject, I beg to direct your attention to a cause heard today in the Westminster County Court. The facts for the medical public may be thus briefly stated:—Several persons residing in rooms over a stable, having died of cholera, a relative, who had been much in the locality, came under my treatment at the Dispensary with neglected colic and diarrhœa, which terminated fatally in *cholera*. An inquest being held, the above simple recital was given by the friends of the deceased, and so much of it as related to the cause of death deposed to on oath by myself. Because I objected, as for years past I have done, to state the medical treatment (a) I had thought fit to adopt, the Coroner adjourned the inquest, that a *post-mortem* might be made by a neighbouring surgeon. He sharply rebuked what he was pleased to designate my shameful behaviour, broadly asserted his belief that I objected, on the score of my having some secret remedy which I would not divulge, or that I adopted a practice I was ashamed to mention.

At the adjourned inquest, Mr. Shaw, who had examined the body, stated his conviction that death had arisen from malignant cholera. The coroner blamed him for not having analysed the contents of the stomach, and added, "that he, at least, whatever the jury might do, should not feel satisfied without the analysis, as the adjournment had taken place in consequence of Mr. Lord's refusing to state his treatment, and to find out what Mr. Lord had put in the deceased's stomach." The verdict, however, was returned of "Death from Cholera," coupled with some expression of surprise or disapproval of my not stating my treatment. The Coroner said, that as I upon principle had objected to tell what I had prescribed for the patient, he upon principle should refuse to pay the fee. As I had attended at the message of the Coroner, sent to me through his constable, I thought it right to ask him, in the presence of Mr. Richard Perry, surgeon, if he declined giving me the fee in consequence of the *informal* notice or order. He replied he did not; he frequently paid where no official summons was issued; that his objection was founded *upon my refusing to complete my evidence*. This morning, however, (though Mr. Perry was in court to have proved the above), Mr. H. M. Wakley pleaded in defence that the summons was made out for the *Coroner*, while he was the Deputy Coroner—that his residence was not "Bedford-street," which was the office of the *Coroner*. These two flimsy objections being over-ruled by the Judge, the Deputy-Coroner obtained a "nonsuit" on the ground which he had disclaimed to me, in the presence of Mr. Perry, viz., that I had not received from him the written formal order, in legal verbal accordance with the Act of Parliament.

It is to be lamented, that the administration of the law differs in different Courts. In September, 1847, Mr. Synot, of Cadogan-place, summoned Mr. Mills to the Bloomsbury Court, for the fee which was withheld, because the usual order for medical witness had not been issued. The Judge, *Mr. Heath*, could have non-suited the plaintiff, I am told, and said that the cause should be conducted by mandamus in a superior Court, where the plaintiff would undoubtedly gain a verdict. He read the judgment given by Lord Denman on the point, and considered the case so clear against the Coroner, that to avoid the expense of being flung into the Queen's Bench, Mr. Mills, the Deputy Coroner, paid Mr. Synot's demand and costs in the County Court.

Reverting to the contemptible grounds upon which the hard-pushed Deputy-Coroner (who does not live at No. 1, Bedford-street,) escaped yesterday from the Court, by shifting the merits of the case to quibbling technicalities, one is apt to call to mind the nursery rhyme, which runs in part thus:—

"Said Lawyer Hawk, 'There is a flaw,
A flaw which I'll explain:
My client you call *Jenny*,
Whereas, her name is *Jane*.'
The Judge declared the solemn plea
Was fatal to the cause;
And then he set Cock Sparrow free:
Cried Robin, 'Hang your laws!'"

In the abstract, I can have as little interest as possible in the issue of such cases, but it is most important for the Medical Profession to be satisfied as to their duty or legal obligation (under pain of Newgate) to answer *all questions under all circumstances* which a Coroner may think fit to put to them. It is right that the Coroner have large powers entrusted to him for public good; but he is apt wrongfully to use this authority. It is most especially wrong that he be allowed to impugn the character of medical witnesses by the mere suspicion engendered through his wantonly calling for recital of medical treatment, the correctness of which a Coroner and jury can know little more about than a man in the moon, and have no power to adjudicate upon, even if they did.

Pray, Mr. Editor, help to put an end to such a farcical manifestation of justice, and such a bullying exercise of "brief authority."

I am, Sir, your obedient servant,
Charles F. J. Lord.
Hampstead, Oct. 16, 1849.

[We cannot help being struck at the injustice of the Coroner in this case. He first neglects his own duty, which was to send a written notice to the plaintiff to attend, instead of a mere verbal message; and he then refuses to pay the fee consequent upon compliance with his request. We hope that our medical brethren will, in all cases, require the proper notice; as, although it may be some time ere such another instance arise, yet there is but one right mode of acting under such circumstances. With regard to the question of evidence, or non-evidence, whatever influence it may have had on the Coroner's refusal, it was, technically speaking, "not in Court."—Ed. *Med. Times.*]

(a) This was muriate of soda and citric acid; frequent subsequent cold drinks, with nitrate of potass in solution.

MEDICAL MEN AND CORONERS' INQUESTS.

[To the Editor of the Medical Times.]

Sir,—I am very much pleased with your leading article on Coroners' Inquests, the law in regard to which, in its present state, I consider to be anything but right, inquests being very frequently held when there is no necessity for them, and very carelessly and improperly conducted where there is. I should say, that no inquest can ever be required where a medical witness is not necessary; and that in many cases where inquests are now held at a great expense to the country, a certificate from a clergyman and churchwardens, or other public officers, should be considered as sufficient,—I mean where death takes place from natural causes in the presence of several persons, and where the Medical man is never summoned. A short time since, I attended a case that terminated fatally, with another Medical man, and we did not agree as to the cause of death, which we expected to clear up on a *post-mortem* examination; but, alas! the coroner held his inquest without summoning either of us, and we remain in the same state of doubt to the present time. I may also mention another case, where I consider the inquest was held very carelessly, and it is only one amongst many similar that I could mention. A man, between forty and fifty years of age, said he felt tired, and would go and lie down. He shortly after called to his wife, and she neglected going to him for fifteen minutes, when she found him dead. I was very anxious for a *post mortem* here; and, as I had no orders to make one, I requested the coroner to give me the order, as it was to gratify myself, and I did not want the fee, and they would object to my doing so except he did. His answer was, "Oh! it is only apoplexy!" I told him it certainly was not. "Well, I am in a great hurry, how long shall you be?" I can tell you the cause of death very soon; I found a rupture of the right auricle of the heart, and a large quantity of blood in the pericardium. What good can such inquests do, or what satisfaction can they be either to Government or private individuals? I should say that where there exists any doubt as to the cause of death, let an inquest be properly conducted, let a medical witness be summoned, and a *post mortem* made; and for this and for every extra trouble, in analysis, &c., let the medical witness be remunerated; and we should then not hear the daily complaints made of the law relating to coroners.

I remain, Sir, your obedient servant,
Tamworth, Oct. 17. R. Cave Browne.

ST. GEORGE'S HOSPITAL. DISADVANTAGES OF HOSPITAL PRACTICE IN ENGLAND.

[To the Editor of the Medical Times.]

Sir,—I address you, as it is in your power to remedy an abuse which exists in many hospitals in London, and more especially in one very celebrated by name for its assiduous and honourable staff of surgeons and medical officers, situated at the West End of London. The abuse I allude to is "the exclusion of all the students from cases of syphilis affecting females, and from all cases occurring in the female wards, which require a private examination." This is not the case in any Continental hospital; and how, may I ask, is a student to become practically acquainted with such cases, if he is not allowed to see them when they occur in his hospital, for which he pays as dearly as at any hospital in England? Can these cases be learned in private practice? The answer must be, No! Must a man be under the necessity of going abroad to study diseases of the uterus? No doubt, they are better taught there; but every student has not money to spend in travelling, and it is well known that the London College does not recognise foreign Hospital practice, or I would venture to say there would be very few medical students in England. To prove this we have also to look at the number of American students in France and Germany. I have only to add, and any medical man may go and see for himself, that whenever there is an interesting case to be examined in the female wards, a screen is put round the patient's bed, and none but the House Surgeon admitted. A screen ought to be put round the bed, and always is; but is it only to prevent the other patients from knowing the nature of the malady under which their fellow-sufferer is labouring, or is it to exclude students, who *pay* for seeing the practice of the Hospital? This has been constantly discussed amongst the students; but no one has yet tried to remedy it, although our more spirited brethren at Bartholomew's did so in their Hospital long ago. A Student.

St. George's, Knightsbridge.

St. Bride's Church-yard, Fleet-Street.—Notwithstanding the crowded state of this cemetery, and the command to close it, fresh interments have been made within the last week. Nothing short of a stringent Act of Parliament will abate these intra-mural nuisances.

CIRCULAR FROM THE COLLEGE OF PHYSICIANS.

With a view to ascertain the best method of treating cholera, and to learn the origin and mode of propagation of that disorder, the Royal College of Physicians some time since appointed a Cholera Committee, who, in September, issued a circular addressed to the medical profession, requesting to be informed as to their several modes of treatment of cholera, and with what success. In order that the Committee may make as elaborate a report as possible, the annexed letter has also been sent to the members of the profession by them:—

"Royal College of Physicians, Pall-mall, Oct. 15.

"Sir,—We are instructed, by the Cholera Committee, to transmit to you the accompanying copies of the letter issued in September, and to request that you will distribute them among those members of the Profession in your neighbourhood, not Members of the College, who have had the largest experience in the epidemic now subsiding. Any aid which those gentlemen may afford the Committee in furtherance of the objects indicated, would be received as an obligation.

"The Committee are so desirous of obtaining your co-operation in a special inquiry respecting the origin and mode of propagation of cholera. They believe, that much might be done towards the elucidation of this important question, by collecting authentic information in regard to the first cases of the disease in the several towns, villages, and public Institutions throughout England. They have, accordingly, directed us to submit to you the subjoined queries, and to beg the favour of your obtaining for them as detailed and precise answers as may be possible:—

"1. Had the person first attacked with cholera in ———, recently been in an infected place; or had he received into his house clothes or other articles which may have conveyed infection, or had he been in contact with strangers coming from an infected locality?

"2. If the disease appears not to have been introduced in any one of these ways, is it possible that the drinking water was the means of conveying the infection by its being contaminated in its previous passage (as a river or canal) through infected places?

"3. What was the character of the part of ———, in which the first case occurred as regards elevation, drainage, supply of water, density of population, ventilation, and cleanliness?

"4. Did the first few cases occur simultaneously, or after what intervals did they succeed each other?

"5. Is there any evidence or probability of there having been communication or near approach between the first patient or patients, and those next affected?

"The following queries have reference to the communicability of the disease, but do not relate especially to the first cases:—

"6. In the instances where several cases have occurred in the same house, have they been simultaneous or successive?

"7. Have any persons attending on cholera patients, or employed to wash the clothes or bed-linen of such patients, been soon afterwards attacked with the disease?

"8. Where several persons in one house, or in contiguous houses, have been attacked, in a district otherwise free from the disease, has it been discovered that the water used for drinking had been contaminated by a sewer, drain, or cesspool, or have any other causes appeared, which would explain the particular limitation of the disease?

"9. Can you learn that the disease has apparently been conveyed to neighbouring healthy places, by infected persons leaving ———?

"In conclusion we have to ask you the favour of an early reply to the present as well as the previous letter of the Committee. It is desirable that all communications should be sent in by the 15th of November, or as soon afterwards as possible.

"We have the honour to be, Sir,

"Your obedient humble servants,

"William Baly,

"William W. Gull,

"Secretaries to the Cholera Committee."

Mr. Purnell, of Charter-house-square, is appointed Surgeon to the Royal General Dispensary, Aldersgate-street, in the room of Samuel Solly, Esq., resigned.

SPIRITED CONDUCT OF PAROCHIAL MEDICAL OFFICERS AT KELSO.

A Meeting of the Kelso Board of Guardians was held on Wednesday, Oct. 10, when a Resolution was passed, by a majority of 6 to 3, that, in consequence of the alleged diminution of cholera cases in the parish, the system of house-to-house medical visitation should be discontinued. The minority strongly protested against this measure, in consequence of the great good which had been effected by the Medical men early discovering and checking cases of diarrhœa. The Medical Practitioners of the town have also made a spirited and decided stand against the foolish parsimony of the Board of Guardians. The supposed saving which will be effected by thus depriving the poor of Medical aid, and exposing a town containing a population of 5,000 to the ravages of cholera, is five guineas a week. Here we have another proof of the impropriety of Boards of Guardians being made Superintendents of the Public Health. The movers of the scheme, a Correspondent informs us, are certain "myrmidons of the law, who, from interested motives, have thrown obstacles in the way of the medical officers." These gentlemen have, in consequence, met and passed a resolution, in which they say, that "they cannot brook an insult of so marked a character, and that they cannot have any further connexion, as to the management of the prevailing epidemic, with a Board so thoroughly ignorant of its legitimate duties, and of the ordinary courtesy due to the members of a liberal Profession." We are sorry to learn that two of the medical staff who signed the document have since "recanted." We conceive that sanitary measures will never be efficiently carried out till medical men are emancipated from the authority of persons who have no proper knowledge of what conduces to the public health, and who are only anxious to effect a present saving of the parochial funds.

MEDICAL NEWS.

Apothecaries' Hall.—Names of gentlemen who passed their Examination in the science and practice of medicine, and received certificates to practise, on Thursday, Oct. 11, 1849:—William Parry, Montgomeryshire; Robert Growse, Bildeston, Suffolk; James Harvey Lilley, Wisbeach; Samuel Brown, Bradford, Yorkshire; John Seymour, London.

Royal College of Surgeons.—The following gentlemen having undergone the necessary examinations for the diploma were admitted members of the College, at the meeting of the Court of Examiners on the 12th inst.:—Messrs. Frederick George Sadd, London; Robert Tassell, Wye, near Ashford, Kent; George Campbell Knight, Chaquar-hill, county Galway; Philip John Vander Byl, Cape of Good Hope; Robert Growse, Bildeston, Suffolk; Thomas Henry Mayne, Templemore, Ireland; Sampson Kingsford Butch, Canterbury; James Walker, Alford, Aberdeenshire; and William Francis Fryer, Kinsale, county Cork. At the same meeting of the Court, Mr. Thomas Seccombe passed his examination for Naval Surgeon; this gentleman had previously been admitted a member of the College, his diploma bearing date May 12, 1848.

Collegial Elections.—From a notice in the *London Gazette*, it appears that the Fellows are to meet in the theatre of the College on the 1st of November next, for the purpose of electing, from among themselves, two gentlemen as Members of the Council in the vacancies occasioned by the resignation of Mr. Richard Welbank, and the lamented decease of Mr. Charles Aston Key;—the vacancy occasioned by the decease of Mr. John Goldwyre Andrews remaining open until the annual meeting in July, according to the provisions of the Charter, that gentleman having been a life member.

Obituary.—On Friday week, in Earle-street, Liverpool, after a few hours' illness, aged 51, Thomas Macartney, Esq., surgeon.—On the 24th of May last, after a few days' illness, at Adelaide, South Australia, James Tweeddale, M.D., Royal Navy.—Mr. H. Wells, surgeon, Warwick-street, Pimlico. Deceased lost his life in a sewer, into which he descended in order to render assistance to three men, who were, subsequently, found to have died from the effects of sulphuretted hydrogen generated in the sewer.—On the 13th instant, at Alton, Hants, William Curtis, surgeon, in his 30th year.—On the 15th instant, at his residence, No. 7, Norland-place, Notting-hill, Samuel Proctor, Esq., M.D., late of Salisbury-square, Fleet-street, aged 64, deeply and deservedly regretted by his family and numerous circle of friends.

Re-Election of a Physician to Bedford General Infirmary.—It appears that, by an informality in the use of "Proxies," the election of Dr. Vaughan Hughes as Physician to this Institution, on the 13th ult., has been declared void, and that a new election is about to take place.

Preston Dispensary.—Ralph Holden, Esq., M.D., Edinb., has been appointed Honorary Physician, in the place of Dr. Heslop, who has resigned.

Society for Relief of Widows and Orphans of Medical Men in London and its Vicinity.—A Half-Yearly General Court of this Society was held at the Gray's-inn Coffee-house, on Wednesday evening, the 17th inst.; Martin Ware, Esq., V.P., in the chair. A ballot took place for the election of Officers and Directors for the ensuing year. Vacancies had occurred in the list of Vice-Presidents, by the death of R. R. Pennington, Esq.; and in the list of Directors, by the death of Dr. Burton, and by the retirement of the other five senior Directors. The following gentlemen were elected, viz.:—As Vice-President, Thos. Arthur Stone, Esq., late Treasurer; as Treasurer, Richard Blagden, Esq.; as Directors, Dr. Nairne, Dr. Jeaffreson, Mr. Charles Hawkins, Mr. Hancock, Mr. Iliff, and Mr. Ansell. Three applications for relief had been received from widows of Members who had recently died of cholera.

London Orphan Asylum.—The vacancy occasioned by the lamented decease of Mr. Charles Aston Key, as Consulting Surgeon to this excellent Institution, has just been filled by the election of Mr. T. B. Curling, of the London Hospital.

The Queen's College, Birmingham.—The Twenty-third Session of Queen's College was opened, on Tuesday week, in the new theatre of the Institution. An inaugural address was delivered by the Rev. Horace Gray, Warden of the College, and Professor of Pastoral Theology. The Vice-Principal afterwards presented the following prizes to those medical students who had especially distinguished themselves:—First Warneford Gold Medal, 25*l*.—Stead, Congleton. Second Warneford Gold Medal, 15*l*.—Mills, Tipton. The Jephson Prize, 21*l*.—Thomason, Shiffnal. Anatomy—Medal and Certificate—Moore, Hales Owen. Anatomy—Certificate—Stead, Congleton. Surgery—Medal and Certificate—Moore, Hales Owen. Materia Medica—Medals and Certificates—Hill, Walsall, and Russel, Brierley-hill, Æq. Materia Medica—Certificate—Roland, India. Chemistry—Medal and Certificate—Fryer, Coleford. Practice of Physic—Certificate—Freer, Stourbridge. Practice of Physic—Certificate—Darwin, Birmingham. Midwifery—Medal and Certificate—T. Lowe, Birmingham. Botany—First Certificate—Wilkinson, Northleach. Botany—First Certificate—Spark, Newcastle-under-Lyne. Forensic Medicine—First Certificate—Lowe, Birmingham. Demonstrator—Book—Partridge, Darlaston. The following Certificates from the University of London obtained at the Pass Matriculation were next presented:—Honours.—Classics and Chemistry: Franks. Chemistry: Lambert, Croydon. First Division—Cantrell, Wirksworth; Coleman, Wolverhampton; Franks, Whittlesea; Lambert, Croydon; Mitchell, Dulverton; Smith, Southam. Second Division—Chatwin, Birmingham; Cockerill, Newport; Day, Chudleigh; Earle, Ripon; Fox, Weymouth; Turner, High Wycombe; Vincent, Oxford; Waller, Chesterfield; White, Birmingham; Williams, Denbigh.

Testimonial to Mr. Postgate of Kilham.—A Deputation waited on Mr. John Postgate, Sur-

geon, Kilham, on Saturday, the 29th ult., and presented to him a handsome silver goblet, as a mark of their high appreciation of his profession skill and moral worth. It must be gratifying to Mr. Postgate to receive such a proof of the estimation in which he is held, especially as he has only been three years settled at Kilham. The testimonial was obtained by public subscription amongst his friends and supporters.

REGISTRATION.—It may save our young friends, the new students at the London Schools, great trouble, inconvenience, and expense, by informing them that, according to the regulations of the College of Surgeons, they should attend at that Institution any day, from the 21st to the 30th inst., for the purpose of registering their cards of admission to Lectures and Hospital Practice.

LUNATIC ASYLUMS.—In a statement presented to the Gloucester Court of Quarter Sessions, on Tuesday, a great increase of lunacy was shown. The number of pauper lunatics in the County Asylum, in 1824, was 60; in the present year, it is nearly 300. The Chairman (P. B. Purnell, Esq.) presented a voluminous Report on the management of the Gloucestershire private lunatic asylums, reviewing many cases of great cruelty which had been brought to light within the last eighteen months, since these asylums had been more closely looked into. In one case, which has already been before the public, two gentlemen had been confined in the Fishponds Asylum, the relatives paying 110*l*. for each per annum, while 350*l*. per annum had been left by their deceased father for the purpose of providing them with every comfort which their deplorable condition could permit of; and the relatives had appropriated accumulations of the lunatics' allowance, to the amount of 8,400*l*., among themselves. The Court of Chancery had marked its opinion of that case by ordering that an allowance of 550*l*. per annum be made for the benefit of the unfortunate gentlemen, instead of 220*l*., as allowed by the relatives. Other cases were alluded to, such as chaining up patients until sores were caused on their limbs by the manacles, confinement in rooms under six feet wide and seven feet high, stripping patients and washing them in a yard with a mop, &c. An application intended to be made for a renewal of a license for the Ridgway House Asylum, and which the Chairman intended to oppose on grounds enumerated, was withdrawn. The thanks of the Court were given to the Chairman for his exertions in this matter.

MORTALITY TABLE,

(Metropolis.)

For the Week ending Saturday, Oct. 13, 1849.

CAUSES OF DEATH.	Total	Average of Five Autumns.
ALL CAUSES	1075	[illegible]
SPECIFIED CAUSES	1072	1158
Zymotic (or Epidemic, Endemic, and Contagious) Diseases	[illegible]	307
SPORADIC DISEASES:—		
Dropsy, Cancer and other Diseases of uncertain or variable seat ...	50	49
Tubercular Diseases	[illegible]	[illegible]
Diseases of the brain, Spinal Marrow, Nerves, and Senses	89	[illegible]

TO CORRESPONDENTS.

MEDICAL SOCIETY OF LONDON.—We have many apologies to make to our readers generally, and to the Members of the Medical Society of London, for the report of the proceedings of that body, which appeared in our last number. It contains many errors, unfortunately of so absurd a nature, that no one could believe such things were said. Mr. Harvey could not have proposed to make incisions "*[illegible]* the [illegible];" and [illegible] context shows that, in [illegible] affections of the ear, where continued [illegible] and tendency to extend over the [illegible] and [illegible], [illegible] the [illegible] [illegible] that [illegible] to [illegible] "*down* to the bone." Dr. Crisp did not [illegible] to the [illegible] [illegible] [illegible] that [illegible] diseases of the [illegible], they might probably prevent some of the [illegible] which so frequently [illegible]. Dr. Crisp did not say that the condition of the blood was the *sole* cause of hæmorrhage, but that *one* form of hæmorrhage was occasioned probably by the condition of the blood. We are greatly at a loss to understand what our reporter makes Dr. Wilshire assert. The reader will observe, however, that some speakers referred to the condition of the blood as the cause of hæmorrhage in scurvy. Dr. Willshire says, "round the seat of inflammation," we suppose the word should be *hæmorrhage*,—and not *inflammation*,—round the seat of *hæmorrhage* is a want of cohesion in the parts, which want of cohesion it is, which has permitted, in fact, the hæmorrhage. In order that this "want of cohesion" shall be produced, a peculiar condition of the circulating fluid (with perhaps other local conditions) is necessary; and in this sense, the state of the blood may be said to be productive of hæmorrhage, inasmuch as it tends to produce the "want of cohesion" to which the bleeding is immediately due. But what Dr. Willshire wants to state is, apparently, that the hæmorrhage in scurvy is not at once due to the condition of the blood, but to the condition of the solid parts,—a "want of cohesion" which has resulted from the state of the blood, coupled possibly with other causes. But after all, this may not be the right reading; if it is not, perhaps Dr. Willshire will kindly communicate with us upon the subject. Similar mistakes, however, *cannot* again occur; and we beg to assure Dr. Copland, that, in future, he may venture to speak at Societies, without the fear of being incorrectly reported in the "Medical Times."

THE WATER QUESTION.—We have received Mr. Tabberner's correspondence with the "Morning Chronicle," on the impracticability of the Henley-on-Thames project for supplying London with water. We shall consider the subject, and probably lay an abstract of it before our readers.

"Mr. Smith, of Belper," writes to us upon the case of Nottidge *versus* Ripley, and "the mischievous effects which, if acted upon, the dictum of the Chief Baron would exercise on the best interests of the insane." The length of Mr. Smith's communication, and the advanced period of the week in which it has come to hand, oblige us merely to acknowledge its receipt.

"Dr. Aldis" will kindly receive our thanks. The report of Cholera cases attended at Twickenham by Mr. Litchfield is very valuable, and will be duly analysed.

"Mr. Wardrop's Work on the Heart."—We beg to inform many inquiring correspondents, that the difficulty of obtaining "copy" from the Author is, in a great measure, the cause of the delay in the appearance of this Work. We wish, with many subscribers, that it was completed.

"Mr. Cave Browne, of Tamworth," is right in supposing we wish our Cholera Table to be returned to us at the termination of the epidemic.

"Dr. Feothern" has our best thanks. His approbation is peculiarly acceptable.

"A Correspondent" is informed, that the fatal accident in the Pimlico Sewer will next week be considered. It is suggestive of many points of comment.

"J. M. B.," will be duly replied to next week.

"Dr. Hobson's" letter from Canton, of the 24th July, has been received, and will be inserted in our next week's Number.

Mr. Ross' "Observations on the Recent Epidemic" did not reach us in time for this week; they shall appear in our next.

"G. M. B." wishes to know if there would be any danger from lead poisoning by giving small and frequently repeated doses of acetate of lead in dysentery or cholera, as recommended by some writers. The acetate may be given to a considerable amount without danger. Dr. Christison states, that he has often given it, in divided doses, to the extent of eighteen grains daily for eight or ten days, without remarking any unpleasant symptoms, except slight cholic. We have given it to the amount of two scruples daily for three or four days without producing any unfavourable symptom.

"Petr." The symptoms produced by sulphuretted hydrogen vary according to the degree of concentration in which it is respired. A person who breathes it moderately diluted speedily becomes insensible. If the gas in a still less concentrated state be respired for some time, coma, or, sometimes, tetanus, with delirium, supervenes. Air slightly impregnated with sulphuretted hydrogen may be inhaled for some time without producing any unpleasant symptoms. The gas appears to act like a narcotic poison when highly concentrated; like a narcotico irritant when much diluted with air.

"An Alean" asks information on the mode of clinical instruction adopted in Germany. Three medical clinics are attached to each school. The pupils are divided into seniors and juniors, the former have the care of patients. A patient on admittance is assigned to a senior student, who takes notes of the origin and progress of the disease under which the patient is labouring, and his state on admittance. These are read at the bedside of the patient on the physician's visit. After visiting the wards, the professor and his class adjourn to the lecture room, where the pupils are examined on the nature of the diseases under their care, their probable termination, and the modes of treatment adopted. Whatever appears erroneous the physician corrects. At the conclusion, the prescriptions written by the students, after having been revised and signed by the professor, are sent to the apothecary. In the German method no regular clinical lectures are necessary.

"A Young Chemist" requires the best mode of analyzing atmospheric air. Dumas' is generally considered one of the best. He allows air to pass over ignited metallic copper in the pulverulent form, in which it is obtained by reducing the oxide with hydrogen gas. The absorption of the oxygen of the air is complete, and the air having been previously dried, and deprived of carbonic acid, by passing through tubes containing caustic potash and oil of vitriol respectively, the increase of weight of the metallic copper gives the quantity of oxygen, and the increase of weight of the globe into which the air is drawn gives the nitrogen, so that the relative numbers are determined with great precision. (2) Gases of unequal densities, placed in contact with each other, ultimately mix.

"M. D." is correct in his supposition.

"Londinensis."—The Apothecaries' Company is compelled to demand of candidates for the certificate proofs of having served a five-years' apprenticeship.

"The Rev. J. Hithersay" will see that his request has been attended to. We always feel great pleasure in recording instances of public respect to the members of the Medical Profession.

"Mr. J. Waddington's" communication has been received.

"Mr. J. Davis."—The subject will be continued as regularly as possibly till concluded, which will be in the present volume.

"A Subscriber."—It would be difficult for us to form an opinion from the conflicting evidence in the newspaper report. The death was singular and suspicious.

ORIGINAL LECTURES.

LECTURES ON OPERATIVE OPHTHALMIC SURGERY.

DELIVERED AT THE CENTRAL LONDON OPHTHALMIC HOSPITAL.

By H. HAYNES WALTON, Esq., F.R.C.S.,
Surgeon to the Hospital, and to the St. Pancras Royal General Dispensary.

LECTURE VII.

Soft Cataract, Operations required for.—Description of Operations.—Results.—Inquiry into Causes of Failure.—Question as to the Propriety of Extracting a Soft Cataract.—Age at which an Operation may be Performed in the Young.—Fragments of Cataract in the Chambers of the Eye.

Soft Cataract.—GENTLEMEN,—A cataract exhibiting the characteristics of softness, all of which have been fully dwelt on, is effectually removed, through the process of absorption, by opening its capsule, and allowing the aqueous humour to be in contact with it. The term "*operation for solution,*" is employed to express this means of cure.

The only instrument required for the purpose is a needle, such as I here show you, sharp at each edge for about the eighth of an inch in extent from the point. It should be spear-pointed, and as delicate as is consistent with sufficient strength.

Cataract needles are generally unnecessarily long, which requires them to be stouter than they need be. Three-quarters or even five-eighths of an inch from the handle to the point, is ample length for any purpose.

There are two methods of effecting the operation, the one through the cornea, the other through the sclerotica; they are designated anterior and posterior operations. The first is more simple and definite, too; for the instrument is never out of view, less injury is done to the eye, the operation is quite as effectual, and is, perhaps, followed by less inflammation, consequently, I generally adopt it. There are different opinions as to the extent to which the capsule should be lacerated, and the opaque lens disturbed. It is a point well ascertained, that the greater the division of the cataract, and the more it is exposed to the influence of the aqueous humour, the quicker it will disappear. Again, more freely the capsule is divided in the first instance, the more effectually does it contract after the cataract has been removed. But there is something else to be taken into account besides merely clearing the pupil. The integrity of the retina must be preserved, or the operation would be useless. It is essential, therefore, not to do too much at once, and thus, perhaps, excite inflammation; for, when it does arise and proceed to any extent, the eye is in great danger. Inflammation may supervene as a secondary consequence. Loose portions of the cataract may, from their presence in the chambers of the eye, induce it. My own line of practice is regulated by the condition of the cataract. When I suspect it to be about as soft, or rather less so than the natural lens, I make but a small slit into the capsule, penetrate the opaque lens but slightly, and rotate the needle in it a few times. It is the "stirring-up," as it is called, of this kind of cataract that tends to induce inflammation. With a large aperture, there is danger of dislocation of the cataract, or of its nucleus, at some future period. Although I have not had personal knowledge of ill consequences from such causes, I am well aware that they do happen, and I endeavour to avoid all chance of their occurrence. In my casebook, I find several instances of dislocated soft cataracts that have been absorbed in from five to seven weeks, without bad results. I saw the lens of a child of three weeks old forced into the anterior chamber from a fall on the head. It quickly disappeared.

I suspect, that is speaking from my own experience, so long as the cataract or parts of it remain in the anterior chamber, there is little to be feared; but when the posterior chamber is occupied there is decided danger.

When the cataract is very soft there can be no fear from dislocation. The soft nature of the opaque mass admits of quick removal, and at the same time is, I think, almost incapable, from its physical properties, of producing injurious pressure. The nucleus, should there be any, will certainly be very small, and its escape need not produce apprehension. Therefore I avail myself of a large central opening in the capsule, and move the needle about in its contents in several directions. Yet I think it safer for it to be absorbed *in situ*. If I think that the cataract is fluid, I endeavour to divide the capsule completely across.

The degree of opacity of the capsule in the two first instances should have some influence in regulating the extent to which it is opened. In proportion as it is dense, is it less likely to split beyond the rent that has been made, and allow the cataract to pass out, while it has a greater tendency to close and unite by adhesive inflammation; therefore it may be laid down, that a larger division is admissible, in proportion to the opacity and thickness. It has been the practice of later years to use the needle very freely in the cataracts of infancy, and when lenticular, purposely to displace the pieces, attempting by one operation to effect the cure. The success attending it shows, that at that age the eye is less liable to take on an inflammatory action.

The posterior operation certainly enables you to break up a lens with greater ease, and to place its fragments in the anterior chamber, (a practice I condemn,) and is, therefore, more commonly adopted in children. Mr. Tyrell told me, shortly before his death, that in eight cases of congenital lenticular cataract in infancy, he performed the posterior operation in one eye, and the anterior in the other. The result was, that all did well, but the eyes in which the posterior operation was performed, and the broken-up lenses displaced, were cured the soonest.

It is, then, a question of time, supposing that both the operations succeed well, and the eyes are alike permanently useful. Mr. Tyrell had not the opportunity of seeing those cases after a lapse of years. Had his life been spared, the probability is, that he would not have heard anything about them; therefore, until it is clearly proved to me, that the vitreous humour can with the greatest impunity be cut and torn, and the puncture of the conjunctiva sclerotica, choroid, and perhaps retina (to say nothing of accident to the ciliary processes and vessels, and nerves) is as little injurious as a puncture of the cornea, I shall adhere to the

passages, I should say that Mr. Tyrell had not a clear idea of the superiority of the posterior operation. Vol. II. p. 374, "The anterior operation for solution is the best and safest in congenital cases." P. 455, "I consider this operation (the posterior one) applicable, principally, to cases of congenital lenticular cataract."

Description of the anterior Operation.—The pupil should be dilated to its utmost. The preliminaries being the same as for extraction, need not be described.

A wire speculum is more adapted than the finger, for raising and fixing the lid in children, and especially in infants, and should be provided. Children should be effectually secured by several assistants. The needle should be introduced through the external margin of the cornea, the point carried to the cataract, and used in whatever manner the operator may desire. With common caution the iris is easily avoided, and the aqueous humour will not escape. I sometimes see surgeons thrust the needle into the eye with great rapidity: why I cannot tell; surely the concussion must be injurious, and with such quickness there is uncertainty where the point of the instrument will go.

The posterior Operation is executed precisely like that for displacement, except that when the needle, which is the same as that used for the anterior operation, is brought in front of the cataract, it is employed for a different purpose. When it is intended to reduce the cataract to fragments, the instrument should be alternately carried forwards and drawn backwards, with a sufficient degree of pressure in different directions, till that object is fully accomplished.

After the capsule is torn it is likely to come into contact with the iris, and become adherent; but, if the pupil is kept well dilated, till the reduction in the bulk of the cataract causes the capsule to recede, the occurrence may be prevented. Sickness and vomiting frequently follow the use of the needle, especially in the anterior operation.

The time required for the absorption of a cataract depends on many circumstances. Besides what has been mentioned, I may add, individual peculiarity, which seems to exert its influence. Under apparently the same circumstances, and the cataract remains much longer in some subjects than in others. The presence of inflammation is said, and I believe correctly, to suspend absorption.

The common practice of treatment by solution is to repeat the operation at intervals, and a specified time is mentioned by some authors. The repetition is grounded on the supposition that the absorption has ceased, or is proceeding very slowly.

A single anterior operation will suffice in perhaps the majority of cases, and certainly always when the cataract is fluid. If, after ten or twelve weeks, there is not evidence in the flattening of the capsule, and the concavity of the iris, that absorption has been proceeding, the operation may be repeated in the same spot, or in some other part of the cataract otherwise there should not be any interference.

When the natural connexion between the lens and its capsule is partially destroyed, the aqueous fluid admitted between them, and its influence exerted on the cataract, that body must be considered as extraneous, and so long as it remains in the eye is likely to be a source of irritation, or at least it produces a state that renders the eye very susceptible of injury. The first use of the needle, if it be employed with care, is seldom followed by much inflammation. Not so with its after applications; then there is a greater tendency to it.

The operation for solution is said to be the safest that is employed for the cure of cataract. That the eye may be less frequently destroyed by it at the time of operating, than by any other mode, I am well aware, but its ultimate results are not superior, or equal to extraction in the aged. The failure or imperfection very frequently arises from the partial amaurotic state, consequent on the inflammation excited, which is not generally of a very acute form, but continues for a long time, in spite of all remedies.

Many cases occur to my mind, and some of them were in my own practice, where too hasty an endeavour to obtain a clear pupil has sealed the fate of the eye. The repetition of the posterior operation is certainly very much more hazardous than the anterior.

When the cataract has been absorbed, the capsule contracts beyond the limits of the natural pupil, or leaves a sufficient aperture for vision, or it may yet remain stretched across the pupil, and require to be removed.

In particular cases the results of the operation for solution may be as good as those of extraction; but the aggregate of them is decidedly inferior. I speak from what I have observed. I must exclude from this statement the operations on infants for congenital cataract, as it is called, or for that kind of cataract at a later period of life, because I have scarcely seen enough of them to entitle me to form a general opinion; and those who have, state that they cannot be surpassed.

Besides the slow inflammation that sometimes tends to failure, I am inclined to think, that the condition of eye producing the cataract greatly contributes to the less perfect result of needle operations. You will remember what I said about the formation of soft capsulo-lenticular cataracts; and soft cataract is almost always combined with opacity of the capsule. The observation cannot apply to congenital cataract, as its mode of production is always ex-

cluded from our observation. The following quotation from Dr. Mackenzie is worthy of your attention:—"Has the process of solution and absorption of the lens no exhausting effects upon the internal parts of the eye? Are these parts left as sound after this process has been accomplished as after extraction? To these questions I must answer, that after the process of solution and absorption is completed, we frequently observe undeniable signs of the internal textures of the eye having suffered, not from inflammation apparently, nor from extraction, but rather from exhaustion. The nutritive, or regenerative power of the eye appears to be weakened. The iris becomes paler and more flaccid than natural, the pupil smaller, and its motions less vivid; while in some cases, the wasting of the eye extends more deeply, the vitreous humour shrinks, and the retina loses its sensibility."

I am unable to account for the imperfect vision that exists after a traumatic cataract has been absorbed, except the "exhaustion" referred to be taken into account. It is very common, that a lens which has become opaque from injury to the eye, whether the capsule has been wounded or not, will, sooner or later, disappear; and, if the capsule has contracted sufficiently to clear the pupil, or when it requires to be removed for that purpose, the sight is so bad as to be almost useless; although, with the exception of the loss of the lens, the eye may appear healthy. Doubtless, the blow that the organ receives, and the inflammation that follows, may sometimes contribute to the amaurotic state; but neither is apparently sufficient, in perhaps the majority of instances, to produce it. The most favourable case that has occurred to me, was in a pupil of the Rev. M. Chorley, of Beaconsfield, to whom I was called. The cornea was wounded with a stick, and cataract followed. About a year after, the young gentleman came to me; the cataract was gone, and the capsule considerably contracted. With a glass he could recognise countenances and read large print. Dr. Farre has recorded a case in which the sight was even superior to this. I am often asked, why not extract a soft cataract? I have been accustomed to say, because, with a simpler operation, the natural powers are quite capable of its efficient dissipation. That when the cataract is much softer than the healthy lens, it would be very difficult, if not impossible, with safety to the eye, to remove it by extraction. A considerable portion of it must be left behind, and, with the immediate risk that belongs to extraction, absorption must still be relied on to perform the work of removal. Then extraction is not applicable to children. Yet I am inclined to think that soft cataract, whenever it may occur, provided it is not softer than a natural lens at any period of life,—a point difficult to ascertain, I admit,—and the patient of an age voluntarily to submit to operation would be better treated by extraction.

The late Mr. Gibson used to extract soft cataracts, in consequence of the ill result of solution. I think that his mode of operating would have been rejected, had his practice been imitated. He lacerated the capsule with a needle, and some weeks after made a small cut in the cornea, and removed the cataract piece meal with the curette. The operation for solution, which is so valuable in childhood, and in very soft cataracts, is, I am convinced, much abused by being employed in the adult cases.

Following the practice of the day, I have been in the habit of restricting extraction nearly entirely to those cataracts that have exhibited the amber colour; but I hope before long to be able to give you the result of a more extensive application of extraction.

Mr. Travers, like Mr. Gibson, being dissatisfied with the operation for solution, resorted to the extraction of soft cataract. His writings on the subject are to be found in the *Medico-Chirurgical Transactions.* His description of the operation is in the fifth volume. He makes a quarter section of the cornea, and with the knife freely lacerates the capsule. He says that the fluid cataract is instantly evacuated with the aqueous humour; the flocculent cataract frequently passes out entire, taking an oblong shape, and the soft caseous cataract piecemeal through the hollow of the scoop, on gently depressing the margin of the pupil and sclerotic.

He adds, if all the pieces were not evacuated, the introduction of the capsule needle was found sufficient to clear the pupil, and they disappeared, in a few days, by absorption.

He had performed the operation on infants; and where the capsule is opaque and inadherent, and the eye not very unsteady, and the child not very unmanageable, he preferred it to the needle. He afterwards states, "but if the capsule is transparent, its contents are generally fluid, or of a consistence almost as permeable and easy of dispersion, and the operation with the needle passed through the cornea, as performed by the late Mr. Saunders, is, if properly executed, unexceptionable."

It is evident, from an earlier paper, in the Fourth Volume of the "*Transactions,*" that he would limit extraction to the hardest kind of soft cataract, and employ the process of solution to the others. I am not aware that soft cataracts are extracted in London at the present day. Why the practice of Gibson and Travers should be laid aside, after their favourable report on it, I am not aware; for there has been no improvement in the use of the needle, nor in the result of needle operations since those gentlemen wrote.

It is not possible, either by words or delineations, to convey such ideas as will enable one unacquainted with the appearance of cataracts to recognise the densest kind of soft cataract. The discrimination must be learned on the subject.

As a cataract once formed never becomes harder, except a calcareous deposit occurs, the time of life at which it is discovered will be a sort of guide, so far as its density is concerned. It can never be harder than the lens at that age would be; but, of course, it may be much softer. Yet, as far as I have been able to ascertain, there is less tendency to soften and to degenerate in proportion as the cataract occurs later in life.

How early in life may an operation for cataract be undertaken? It is better not to defer it till the oscillation of the globes has commenced. I should perform it soon after the second month, or even earlier, were the child in good health. If the presence of any portion of cataract in the anterior chamber should be producing irritation, after means for subduing that inflammation have been ineffectually resorted to, the offending body must be extracted, the opening in the cornea being adapted to its size. It would be bad practice to resort to extraction till there was evidence of the body becoming injurious, because such an occurrence is the exception. This is different advice to what I gave when speaking of dislocation during displacement, when the cataract would be hard. When inflammation proceeds from the presence of irritating bodies posterior to the iris, you must, as a last resource, try, by extraction or displacement, to remove them. Fortunately, I have never had to deal with such cases.

It would be unnecessary to give any advice for the treatment of inflammation that may arise after the employment of the needle. It is enough to say, that it is not necessary to confine the patient to his bed, as after extraction. Remaining in the house for a few days, and taking care that the eye is well shaded, form the essential part of the after-treatment. Belladonna should be constantly applied, for some weeks, to prevent adhesions.

The pupil is not altered after the use of the needle, except it become adherent to the capsule. After extraction, even when not prolapsed or adherent, it may be irregular; for sometimes the iris does not recover its function at the spot over which the cataract escapes, and which has been most stretched.

INTRAMURAL BURIALS.—Interments in Spain, in churches, churchyards, and private burial-grounds are summarily interdicted, except as regards archbishops, bishops, and nuns. At Castello de Ampurias, in the neighbourhood of Figueras, (Catalonia,) the interment of a corpse in a cemetery, was riotously opposed by the inhabitants; and soldiers were obliged to be called out to quell the rioters.

ORIGINAL CONTRIBUTIONS.

RETROVERSION OF THE UTERUS AS A CAUSE OF STERILITY.

By EDWARD RIGBY, M.D., &c.; Senior Physician to the General Lying-in Hospital; Examiner in Midwifery in the University of London.

(Continued from page 281.)

In my last report I gave a case of retroversion successfully relieved by the application of the uterine supporter. I quote the following case as an instance of those cases which, as yet, have resisted all the means that have been adopted for their cure. There is no doubt but that most of them have been of such long duration as to give little hope of the uterus returning from a position or a curvature which had become habitual and almost natural to it, unless the lucky occurrence of impregnation shortly after the removal of the supporter had been the means of removing also the displacement.

S. B., aged 30, married ten years, suspects herself to have been pregnant once; tall, stout, and well made.

Nov. 9.—States that she has long suffered from dysmenorrhœa; the catamenia, though regular in their appearance, are scanty and filled with shreds; for three or four days before a period, she frequently has a puriform discharge, with pain across the loins and in left ovarian region. The bowels are confined; she complains of irritability of the bladder; the urine is thick; there is pain in the region of the sacrum, and on sitting down upon a hard seat. She has long been subject to a sensation of fulness and weight about the pelvis. She had only two catamenial periods before marriage; the first of which she checked by bathing with cold water, since which they have been attended with dysmenorrhœal suffering: supposes that on one occasion she had a very early abortion.

Examination per Vaginam.—Os uteri looking forwards; cervix very short; fundus turned backwards: I replaced it.

℞ Acidi hydrochlorici dil., acidi nitrici dil. aa. ʒij.; syrupi auranti, ʒi.; aquæ cinnamomi, ℥iss.; M. ft. mistura cujus sumat cochl. min. i., ter die ex aquâ.

℞ Sodæ potassio tart. ʒiss., om. mane.

℞ Linimenti camphoræ co. ℥ijss.; tinct. opii, ℥ss.; M. ft. linim. lumbis et sacro infricand.

Dec. 9.—Continued easier as regards the sacral and ovarian pains until the next period (Nov. 27); she had no pain previous to the period, except a moderate degree in the back for two or three hours before it came on, just where the pain ought to be on these occasions. She had little or no pain in the ovarian region, and no exudations in the discharge. The period lasted only two days; it was moderate the first day, and very trifling the next. The bowels have been more regular, and in better order; appetite and sleep are good; pulse weak; tongue clear, but pale; complains of vertix headache.

℞ Ferri sulphatis, gr. xvi.; magnesiæ sulph. ℥i.; acidi sulph. dil, ʒi.; syrupi rhœados, ℥ss.; aquæ menthæ pip. ad ℥viij.; M. ft. mistura cujus sumat cochl. magn. ij, primo mane vel bis die.

Feb. 17.—As her former symptoms had returned, I introduced the uterine supporter; being only a few days before the next period, the ivory peg passed with some difficulty and pain.

Feb. 20.—Kept her bed the rest of the day after the application of the supporter, but, since that, has worn it with less and less uneasiness, and has been up as usual; shortly after which she returned to her home in the country.

March 3.—Writes that she performed the journey successfully. The catamenia appeared upon the 1st. She says, "I have been much better in that respect than I ever was in my life."

April 4.—Has just passed another period, which was better even than the last, and came exactly at the right time, still she suffers a good deal of pain, and uneasiness at times, and has a considerable leucorrhœal discharge. After wearing the supporter two months it was removed, and she soon began to suffer again from her former symptoms. u-

strument was again applied. After wearing it for some time it was altered, so as to give the uterus still further inclination forwards. She wore it, in all, four months, but, on removing it, the symptoms of retroversion began to show themselves in a few days. I advised her to try the prone position as much as possible, but, beyond having improved in her general health, she does not appear to have benefitted as regards the displacement.

Although the treatment with respect to the retroversion was unsuccessful, still the temporary restoration of the uterus to its natural position was attended with effects which are interesting. Until the application of the supporter, the catamenia had been preceded by considerable dysmenorrhœal suffering, and attended with exudation, indicative of the ovarian irritation which so frequently attends retroversion of the uterus, and which had been aggravated, if not produced, in the first instance, by the suppression of the menses from cold. Both of these symptoms were very decidedly relieved by the application of the supporter, a fact which is also interesting, as a proof that the presence of this instrument was not a cause of uterine irritation during the catamenial period, but in this case a means of relief. The pain almost entirely ceased, the exudations disappeared, and she declared that the period had passed more comfortably than ever she had recollected it before. She still continues to use the prone couch, which, although it does not entirely cure the retroversion, nevertheless relieves it considerably; for not only have the menstrual periods been much better, but the general health has improved considerably.

H. D., aged 37; married 12 years; has been a widow for nine years; never pregnant; feeble.

April 3, 1848.—Complains of constant uneasiness, not amounting to pain, in the thighs, with a sensation of dragging and bearing down, whenever she exerts herself in the upright posture. Suffers also from pain in the last joint of the spine, which is increased for a week before the catamenial periods, and is accompanied by a sense of painful lassitude, which never entirely leaves her. Frequent palpitation of the heart; bowels inclined to be irritable and offensive; tongue rough and dry; urine turbid; much intestinal flatulence; was formerly subject to patchy flushings of eruption upon the face, which still appears occasionally when she is much agitated. Has been under the care of another practitioner, who detected the presence of retroversion, but found the system, both locally and generally, too irritable to bear the application of the uterine supporter.

Examination per Vaginam.—The uterus is retroverted. I replaced it, and recommended her to try the prone position.

℞ Extr. taraxaci ʒj.; liquoris calcis ℥viij.; M. ft. mistura cujus sumat cochl. magn. ij. bis die.

℞ Liq. plumbi diacetatis, ʒij.; decoct. papaveris ℥viij; M. ft. lotio.

April 6.—Looks and feels much better, and thinks that the medicine agrees well with her. She has for some years past been in the habit of applying leeches to the labia just before a catamenial period, in order to produce a sufficient relief to the system, as she supposes; this I strongly discountenanced. Rep. med.

April 9.—Catamenia came yesterday sparingly, but without pain. Rep.

May 5.—Feels better, but is subject to much mental depression; she continues the prone couch with comfort. Rep.

The retroversion, as in some of the previous cases, was probably in great measure dependent on general debility and want of tone, which she had tended not a little to perpetuate by the practice of applying leeches just before every catamenial period. The frequent palpitation of the heart—the continuous and painful lassitude, and feeble state of the general health, point to the same condition; and it is worthy of remark, that, under such circumstances, retroversion can occur as well in a patient who has never been pregnant as in the mother of many children.

I have selected this case as being one of the earliest in which I trusted entirely to the use of the prone couch; the extreme irritability of the system, both locally and generally, rendering the application of the supporter impossible. She experienced great relief from the use of the prone position, although the disposition to retroversion in her feeble and relaxed habit has never been entirely removed; and only within the last week I have heard from her, stating, that she continues to use the prone couch occasionally, and never has recourse to it without relief.

A. P., aged 38, single, tall, emaciated, pale, haggard.

June 25.—Complains of sensation of weight in the pelvis, with pain and heat in the left side, and hot smarting pain of the left groin. These pains are increased by confined bowels. The fæces are very small, and flattened, and will not pass without an enema. There is considerable irritability of stomach, continuing at times for several days, with derangement of vision, tinnitus aurium, headache and other anæmic and nervous symptoms; complains that as soon as she sits erect there is a sensation of something within her falling down. Was thrown from a gig nine years ago, and received a severe blow upon the sacrum, from which time she dates the symptoms of which she complains. She underwent a course of hydropathic treatment, but without success. After this she consulted another practitioner, who considered it to be a case of inflammation of the uterus, with hypertrophy, for which he applied leeches some sixteen or eighteen times, with other depleting measures. This plan of treatment lasted ten months, and left her very weak, and, as she expresses it, "the mischief, though subdued, still remaining." Says she cannot take tonics.

Examination per Vaginam.—There is no uterine enlargement; it is a simple case of retroversion, which was easily reduced. I enjoined the prone position. ℞ Acidi hydrochlor. dil. Acidi nitrici. dil. aa. ʒii., syrupi aurantii ℥i., aquæ cinnamom. ℥iss., m ft. mist. cujus sumat. cochl. min. i., ter die. ex aqua.

July 6.—Complains that she feels weak, that her appetite is bad, &c. &c.; but, on the whole, acknowledges to being decidedly better. The bowels are confined: tongue furred.

℞ pil. hydr. gr. iij., quinæ disulph. gr. ij., extr. coloc. co. gr. v., m ft. pil. ij. h. s. s. Let her continue the prone position.

℞ Confect. rosæ ℥i., acidi. sulph. dil. ʒi., decoct. cinchona, ℥xij. misce. coque, et cola bene, fiat mistura cujus sumat cochl. magn. iij. bis die.

July 13.—Thinks that the cinchona disagrees with her, but is manifestly better as regards the symptoms and effects of retroversion.

℞ Acidi hydrochlor. dil., acidi nitrici dil. aa. ʒi., extract. taraxaci ʒi., infusi gentianæ co. ad. ℥viii., m ft. mistura cujus sumat cochl. magn. ij. bis terve die.

July 19.—Bowels confined, but has lost most of her former aches and pains; felt obliged to discontinue the last mixture after a while; nevertheless, it has evidently done her good. Returns home.

℞ Extracti aloes aquosi ℈ii., extr. hyosc. ℈ss., mastiches gr. xij., m ft. pil. xv. sumat i. ij. h. s. Rep, mistura. p. r. n. A seidlitz powder occasionally.

September 5.—Writes word that the prone position has relieved and strengthened her; she resorts to it as a remedy for pain; complains of suffering from indigestion, but moves about much better.

I have weeded my report of a long list of aches and pains which this patient enumerated; suffice it to say, that she had become much emaciated, and entirely confined to her sofa for some time, being unable to make any exertion without bringing on severe pain. That the fundus uteri had exerted considerable pressure on the rectum is evident from the compressed state of the fæces, and their inability to pass without the aid of an enema; that it was tolerably moveable in this displaced state may be inferred, not only from the fact, that I replaced it with great care, but that she had the sensation of something falling within her when she sat erect.

There can be little doubt but that the retroversion was produced in the first instance by a severe fall on the sacrum. The depleting measures which were adopted relieved for a time the sufferings arising from the congested state of the uterus, but, as the cause remained untouched, they quickly returned as before. The irritability of the system and constitutional disturbance which had resulted from the displacement were probably a good deal aggravated by the weakening effects of the treatment; her own prejudice against tonics did not improve this evil, and it was with some little difficulty that I overcame her objection to take the simple mixture of nitro-muriatic acid, which in the first instance I prescribed for her.

OBSERVATIONS ON THE RECENT EPIDEMIC CHOLERA.

By GEORGE ROSS, Esq., late Medical Officer of the West London Union, author of "Lectures on the Asiatic Cholera," &c.—Medical Times.

The Registrar-General has stated, in his last Report, that the West London Union "has been the most fatal district north of the Thames;" and as I was appointed by the guardians of the Union to take charge of the cholera cases occurring in the parish of St. Bride's and a portion of St. Sepulchre, where the largest number of cases occurred, I had abundant opportunity of acquiring a knowledge of the disease. My personal experience has enabled me to qualify and correct some parts of my former writings, which were merely the result of an examination and collation of the observations of others. These corrections, however, will not tend to subvert any principles already adduced, but rather give precision and clearness to many points then left obscure. In my lectures on cholera, which were published last year in this journal, I formed my inductions from facts, and carefully avoided attaching any value to opinions, and as well observed facts will exhibit the same characteristics and involve the same inferences in 1849 as in 1832, the conclusions then formed are not likely to be perilled by future inquiries. We must hope that new principles may be discovered, our ignorance dissipated from many dark crypts, and the circle of our knowledge extended; but hitherto, neither much illumination nor progress has been effected. The recent observations of Messrs. Brittan and Swayne, especially in reference to the presence of the principles of the urine in the choleraic evacuations, are of considerable interest. It is not, however, my object at present to review the labours of others, but merely to record such observations as have pressed their importance upon my own mind.

When cholera first ravaged the West London Union, the number of cases of diarrhœa was small, as compared with what it afterwards became; and the cases of cholera were peculiarly unexpected and fatal. Before my appointment as "public officer," I had seven cases in private practice under treatment at the same time, five of whom died. One only of these five, however, died within the twenty-four hours; the others lived to periods of five, nine, and ten days. Each of those persons had been previously subject to biliary disorders, and one of them had been attended by me last year for bilious purging, terminating in rice-water evacuations. This patient succumbed. In all these cases there was, therefore, a predisposition to cholera, and in some of them sickness, diarrhœa, and uneasiness at the stomach had existed for some time previous to the attack assuming a character sufficiently imminent to alarm the patient.

At this period, and for six weeks after, the disease was of a different type, or bore a different relation to other diseases from what it subsequently assumed. This difference was very remarkable, and, to a great extent, accounted, in my judgment, for the varieties of opinion as to the pathology and treatment of the epidemic that have been promulgated. During this early period the concurring disease was ordinary bilious cholera, and the epidemic cholera appeared to be nothing more, in many instances, than an aggravated form of the simpler disease. The rice-water stools were generally preceded by bilious vomiting and purging,

and, in one or two remarkable instances of prolonged duration, I observed an alternation of one with the other—sometimes the liquid rice-water, and at others the bilious purging.

In the notes of a case now before me, I find that it commenced with bilious purging. The evacuations then became rosy, liquid, and flocculent, like the washing of fresh muscle, and were accompanied with suppression of urine. The dejections were afterwards brown and feculent. On the following day, the matters vomited were tinged with bile; but the intestinal evacuations had all the characters of rice-water purging, and at this period decided collapse was established.

As a general rule, the more profound the collapse the more limpid and colourless will be the intestinal discharges; but if the inexperienced practitioner should expect to find, in every case of cholera, the white liquid stools described as pathognomic of the disease, he would be grievously disappointed. The watery evacuations are generally tinged of a dirty brown colour, and the virgin-white rice-water stool is a rarity. The ordinary colour is a dirty ash or light brown; it is occasionally shaded with yellow, or is of a light rose colour, or plain white.

During the first six weeks of the prevalence of the epidemic in this part of the Metropolis, th disease exhibited no signs of complication wit diseases of an inflammatory type. Whilst tl patient was in collapse, the pulse was generally 12 in the minute, but I observed that the tongue wa natural, or only very slightly furred at the root. I seemed as if the patient had been struck with tl disease in the midst of the ordinary healthy per formance of his vital functions. By far the greate number of my cases at this period died during th stage of reaction, and I had opportunities of watch ing them narrowly, so as to form a clear estimat of the value of every symptom.

The stage of re-action has been called the *febril* stage, and elaborate theories have been based on th notion. The fever is generally termed typhoid; b I have seen a great deal of typhus fever, and hav already delineated its nature and symptoms wit much minuteness; and I am prepared to assert, that during the re-action from the collapse of an uncom plicated attack of Asiatic cholera, there are n symptoms that bear any analogy to typhus fever.

The course of the disease emerging out of col lapse is this:—The pulse, from being about 120, o: inconstant, and almost extinct, becomes full, and falls to 100 or 90, the face flushes, the dampness o the surface disappears, and the hands and feet acquire warmth. This febrile stage will continue on the average 36 hours, at the end of which time the pulse will commonly fall to its natural standard but the tongue, when the case is likely to terminate in death, becomes covered with a greenish brown moist coat, and its breadth seems to be even greater than natural. This kind of tongue has, no doubt, given rise to the notion of the typhoid character of the disease; but most unjustly, for no one ever saw such a tongue in typhus. The tongue in typhus is generally *contracted and dry*, and the fur is browner than the peculiar greenish-looking moist coat in cholera. Besides, during this period of the reaction there is absolutely no fever; the skin is generally warm and natural, or perspiring, and the pulse in some cases, as in a report of one now before me, not more than 72. I have seen several patients exactly in this condition; they have seemed all but well, have actually dressed themselves, and I have profoundly regretted that I have not been able to avert the death that awaited them. I emphatically state, that a patient may remain in this condition, without any sign of fever, for three or four days, as it were balancing between life and death; and these days are precious, for they afford opportunity to the medical man for the exercise of his saving art. These days past unimproved usher in death. During this time there is suppression of urine, and this symptom, together with the peculiar condition of the tongue, seem to be the only abnormal signs requiring attention. The urea retained in the blood is poisoning the system, and gradually affects the brain. This state is peculiar, but is altogether different from typhus fever, and never could be mistaken for it except by a blind and undiscriminating theorist. I have heard it described as "delirium tremens," which it far more resembles than typhus fever. Cholera in the concrete has been likened also to an intermittent fever, but without any sufficient evidence to support the analogy; and I believe that the strongest evidence of that opinion is furnished by myself in these very observations; but, in truth, my perceptions can discover no such similitude. If the suppression of urine not removed, and the exhaustion of the system not restored during the few days left for the administration of remedies, a febrile state will sometimes again set in. The pulse quickens, and the face flushes, whilst the extremities remain cold; the trunk, however, acquires increased warmth; and, notwithstanding these delusive symptoms the patient eventually dies. At this period, thickness of utterance, tumefaction about the throat, and delirium, are well marked. This state may remain also for twenty-four or thirty-six hours. I do not regard these as two paroxysms of intermittent fever,—the first febrile stage appears due to the specific poison of cholera; the second to the poisoning by urea. I have observed, that when patients have died in collapse, a very considerable augmentation of the heat of the body has in some instances taken place a few hours before death; and I apprehend, that this morbid action has misled numerous Practitioners, as it did myself in the first cases I attended, in forming an opinion upon the influence of the medicines they have administered; for nothing is more common than to read, that calomel, or salt, or brandy, or galvanism, or what not, succeeded in restoring the heat of the body, but that, notwithstanding, the patient died. All such statements it must be suspected were set down in error. I shall dilate more upon the treatment of this disease during the stage of re-action at a future time.

From about the middle of June, when the disease first appeared here, to the beginning of August, I had seen no cases of colic, as distinguished from bilious cholera; but on the 2nd of this month several patients applied to me who were suffering from a violent twisting spasmodic pain in the bowels around the umbilicus, and I had hopes that the epidemic was about to change its character, but I was deceived. These cases of colic prevailed for two or three days, then disappeared, and I have not seen another up to this time. I think this observation of considerable interest as respects the natural history of the epidemic, but I can give no explanation of it.

A peculiar epidemic constitution of the atmosphere, producing similar results, occurred about July 6. On that day and the following, several ersons, generally women, applied to me under rious forms of heart affection; some complained of severe lancing pain under the left breast, others of violent palpitation; and these cases were occasionally accompanied with, or terminated in, convulsions, either hysterical or epileptic, with external ongestion, or delirium. Six of these cases occurred n one day, and I referred them to some unknown ause existing in the atmosphere. A Practitioner n full employment in a given locality cannot mistake the peculiar significance of such diseases. I nce saw a young woman who had been struck by ightning, and for many days she remained in a eculiar hysterical state, resembling very much the ndition of these patients.

Although none of these cases died, yet I was apprehensive for the fate of more than one of them, nd I have no doubt, that those cases of cholera, called, in which no vomiting or purging has been bserved, are cases of this character, and are produced by the same cause. I have never seen a ase of cholera without vomiting or purging, and ave doubts about the propriety of assuming that ere are any such cases; but I am quite willing to dmit, that in a particular condition and temperture of the atmosphere, patients may be struck own suddenly, and death take place by arrest of e heart's action, and universal congestion. This ppens frequently in India, and the cases I obrved were, no doubt, of a related character; but, I think that it is imprudent to call them cholera, or dry cholera, or any other name that may mislead the judgment.

I shall conclude this paper, with a brief description of cholera, as it appeared during the last six weeks of its visitation. From about the middle of August diseases of a gastro-enteritic type began to prevail, and it was often very difficult to draw the line of demarcation between pure gastro-enteritis and cholera. Symptoms of gastro-enteritis would exist for a few days, accompanied with vomiting and purging of a fluid, in all respects resembling the ordinary ejections in cholera, and, at last, collapse would suddenly come on, and death close the scene. Premonitory symptoms, as they are called, were noticed for some days in this form of disease, but these premonitory symptoms were, in fact, a specific disease. Cholera, it might be said, was induced upon them. In these cases, the tongue, instead of being natural, as it was during the first period of the epidemic, was red at the tip and edges, and was covered with a slimy coat, or was even clean and raw-looking like a slice of beef; there was also more pain and soreness across the epigastrium and abdomen, and occasional accessions of fever. Such cases were rife; and cholera rarely occurred at this period, unless complicated with this form of disease. A stranger first seeing a case of cholera at this time would be led to consider it a form of gastro enteritis, and be the advocate of leeches and depletion; whilst another, who had an opportunity of observing the disease only in the earlier periods, might become the eulogist of an opposite plan. I am particular in defining these distinct manifestations of the disease at different periods; because, until I had an opportunity of observing the disease upon an extensive scale, I had no means of reconciling the discrepant opinions formed by men of equal powers of observation and medical skill respecting the pathology and treatment of cholera.

I apprehend that upwards of one-half of the deaths reported as the result of cholera to the General Board of Health, during these last two months, have been the consequence of gastro-enteritis, intensified by the epidemic influence abroad in the air or water. I feel satisfied that many of these cases ought to have received another denomination, as I am quite sure that the treatment they require, is, in many respects, different from what would be beneficial in genuine cholera. During the stage of re-action pyrexia was almost invariable, and was dependent upon the inflammatory state of the stomach and bowels, and, towards the last few days, typhoid fever set in, and ultimately carried off the patient. The typhoid fever, however, though following cholera, had no direct relation to it, but was essentially a part of the gastro-enteritis. The re-action, therefore, in these two forms of the disease, manifests different symptoms, and requires different treatment.

Cholera, then, must be considered in reference to its complication with gastro-enteritis or otherwise, and it will thus be seen by any reasonable man, how absurd must be those systems of treatment which are required to be applied indiscriminately to all forms of the disease, upon the assumption that cholera has but one set of symptoms, and stands out independent of all complications,—a model disease to be cured by an infallible remedy. The Profession may depend upon it that they will never be able to discard observation and judgment, or to set at naught established principles of therapeutics in the treatment of this formidable disease. The man who asserts, that he has a specific for cholera, and who attempts to deprive us of our right of judgment by binding us down arbitrarily to certain empirical forms of cure, without reference to time or circumstance, is a quack,—not the less censurable, because, perhaps honoured with a doctor's gown, and doing lip-service to legitimate medicine.

WAR MEDAL.—T. H. B. Grosse, Esq., surgeon, of Kempsey, has received a medal in acknowledgment of his services on board H.M.S. Musquito, in Sir Edward Codrington's action off Navarino, October 20th, 1827.

HOSPITAL REPORTS.

ST. THOMAS'S HOSPITAL.

DEATH FROM CHLOROFORM.

John Shorter, age 48, a porter, known to Mr. Solly for some time as a very active messenger. Habits intemperate, but apparently in perfect health, was admitted into George's Ward, under Mr. Solly, on the 9th October, 1849, suffering from onychia of the left great toe, which had existed some time. It was determined to remove the nail, the man having decided, before entering the Hospital, on taking chloroform. On Wednesday, 10th October, at a quarter to two p.m., he began to inhale the chloroform, with one drachm in the inhaler. It had no visible effect for about two minutes. It then excited him, and the instrument was removed from his mouth, and about ten drops more were added. He then almost immediately became insensible. The chloroform was taken away from his mouth and the nail removed. He continued insensible, and his face becoming dark, the pulse small, quick but regular, respiration laborious, his stock was removed and the chest exposed to fresh air from a window close to the bed; cold water was dashed in his face, the chest rubbed, and ammonia applied to the nose. After struggling for about a minute he became still, the skin cold, pulse scarcely perceptible, and soon ceased to be felt at the wrist; respiration became slow and at intervals, but continued a few seconds after the cessation of the pulse. Immediately on the appearance of these symptoms artificial respiration was commenced by depressing the ribs with the hands and then allowing them to expand again until the proper apparatus was brought, when respiration was kept up by means of the trachea-tube and bellows, and oxygen gas introduced into the lungs by the same means. Galvanism was also applied through the heart and diaphragm; but all signs of life ceased in about six or seven minutes after the commencement of inhalation. These means were persisted in until a quarter past three, but to no purpose. On removing the inhaler, the sponge, which only contains one drachm, fell on to the floor, and the chloroform splashed about, thus showing that considerable part of the chloroform remained unused, so that he could not have inhaled more than a drachm. Every endeavour was made to procure a *post mortem* examination, but in vain.

VINCENT'S HOSPITAL.

DISEASE OF THE HEART.

A man, aged 57, admitted under the care of Dr. O'Ferrall on account of laborious breathing and anasarca. His lips, cheeks, tip of the nose, and hands were of a purplish hue. He frequently sought relief, by kneeling and resting his head upon his crossed forearms placed on the bed. In this position, in which his hips were higher than his shoulders, he would remain for hours. His extremities were cold; the pulse almost imperceptible at the wrist; when detected it was found to be irregular and frequent, and of extreme minuteness. When his chest was examined in the sitting posture, it was comparatively dull posteriorly, especially towards the base, where a submucous crepitus was audible. In front, it was rather clear on percussion, and the respiration feeble, with but few rales. No pulsation in the proper cardiac region; the heart could be felt throbbing behind the xyphoid cartilage. A loud systolic *bruit de soufflet* was audible in this situation; its intensity was greatest about two inches to the left of the xyphoid cartilage. There was no morbid sound along the course of the aorta. Urine scanty and high coloured.

An attempt was made to relieve him by mercurial and diuretic treatment, aided by cupping the posterior part of the chest. His dyspnœa was occasionally relieved by diffusible stimuli, and he was allowed nourishment. After a few days, mercurial fœtor was perceptible from his breath, and he expressed himself a good deal better. The anasarca of the limbs still continued, and the pulse remained filiform as before. The dispnœa again returned as bad as ever, and he at length succumbed.

Autopsy.—The sternum being raised, the anterior half of both lungs presented the emphysematose condition in a remarkable degree, the pericardium lying lower down and more to the middle line than in the natural state. About eight ounces of sanguinolent serum were found at the posterior part of either chest. The lungs in these situations were dark-coloured, congested, but still crepitating when pressed between the fingers. The pericardium being opened, the heart was found remarkably large; two-thirds of its bulk consisted of the enlarged right ventricle which formed the apex of the heart. The auricles were remarkably distended with blood. On section, both ventricles contained solid blood of the colour and consistence of black currant jelly. When the chambers were washed, the aortic valves were found healthy, and more than competent to close the aorta, the dimensions of which were smaller than usual. The right, or anterior portion of the mitral valve was shorter than usual, so that when drawn in front of the left auriculo-ventricular opening, and made to approach its fellow, it left a cribriform passage towards the left auricle through the tendinous cords. A few points of thickening could be felt in the larger portion of the valve, but there was no atheromatous or calcareous deposition whatsoever. The auriculo-ventricular aperture was, at the same time, very much larger than natural, and readily permitted three fingers to pass together into the auricle. There was no evidence of morbid change in the walls of this aperture. The auricle itself was considerably dilated, as well as the right auricle and ventricle.

Remarks.—Considering the dimensions of the left auriculo-ventricular aperture, and the mechanical condition of the valve, there can be no reasonable doubt, that a considerable proportion of the blood upon which the left ventricle contracted, returned at each systole into the auricle, while little passed into the aorta. The character of the pulse was thus satisfactorily accounted for, and the diminished calibre coincided with this explanation, and marked the habitually diminished current through its tube. The evidence of this reflux was next observable in the dilated left auricle, the congested lung, the large pulmonary artery, the dilated right auricle, and large dimensions of the right ventricle, which in this case formed the apex of the heart.

It is not unusual for anatomists seeing the body for the first time in the dissecting-room, and entirely unacquainted with the previous history of the disease, to announce that there is very little the matter with the valve, unless it be studded with vegetations, or filled with calcareous deposits. If the inadequacy of a shortened valve be pointed out, and its want of relation to a dilated orifice, they will perhaps say, that the two laminæ of the mitral valve come together in proportion as the ventricle contracts, and that thus the cribriform aperture is obliterated; and hence they conclude that no regurgitation could have occurred. Now, it may be readily admitted, that when the ventricle has contracted on its contents, the two portions of the valve may come together, so as to close even a dilated orifice; but it is evident that this is too late to prevent reflux, and that, at the point of time when they come in contact, regurgitation and its physical signs have already taken place. At the time when the ventricle commences to contract, its orifice is patulous, and its cavity is distended with blood; its first systolic effort, therefore, must be attended with a reflux through the auriculo ventricular opening, as well as with a normal current through the aorta; and this is all that is necessary to produce the phenomena of the present case.

PROGRESS OF MEDICAL SCIENCE.

FRANCE.

(From our Paris Correspondent.)

I can at length positively announce to you the complete disappearance of epidemic cholera from Paris. For several days not a single fatal case has occurred, either in hospital or private practice. There will be, of course, a dropping case, from time to time, and it is possible that we may experience a second visitation, even more serious than the first; but for the present we are free, and it is useless to speculate on possibilities—"Sufficient for the day," &c., as the proverb says.

The accounts from the south of France are likewise more encouraging. Indeed, the warm imaginations of our southern friends seem to have aggravated, in no small degree, a state of things by no means so dangerous as was represented. Fear, like drunkenness, sometimes makes people see double. From the southern ports the epidemic has extended to Algiers, and thence is now spreading to the foot of the Atlas. In the town of Algiers itself, the population, and more particularly the garrison, has suffered very severely. Of 909 soldiers attacked, 523 have died, being about one-fifteenth of the effective force of the place.

This is exactly the same proportion of mortality which prevailed amongst the soldiers of the garrison of Paris—a fact which shows how little the epidemic seems to be modified by climate. Another point worthy of attention, and which fully confirms the remarks of Dr. Budd, in an excellent lecture, published in your last number, is the immense proportion of medical attendants who were attacked in the military hospitals of Algiers. Of 179 infirmary attendants, no less than 51 died of cholera; and we may conclude that 100 at least, or three-fifths of the whole, must have been attacked by the disease.

In presence of such a fact, it is impossible not to conclude with Dr. Budd, "that the disease is, in some way or another, infectious." Indeed it may be questioned whether the records of fever hospitals ever presented a more striking example "of great concentration of the poison in particular places." The greater part of the victims alluded to had recently arrived from the military hospitals of the south of France, together with thirty military surgeons, on supplementary service. Many of these latter have also been cut off. Five hospital surgeons at Lyons have already perished, and the last accounts from Marseilles bring the news of the death of M. Mathieu, head physician to the Hotel Dieu of that town, and a young practitioner of the highest promise.

We were somewhat astonished here at the noise made in England about the phenomena which attended the death of young Mr. Blythe. The persistence, or rather development of animal heat after death from Cholera, was a phenomenon we thought familiar to every medical man who had any experience of the disease. But some practitioners cannot live unless people talk about them, and a few of the Bristol folk appear to belong to this category.

The following is a case just as curious, but I do not, of course, vouch for its authenticity.

"A comfortable burgermeister of the city of Utrecht was attacked by cholera, and cut off within a few hours; at least, his friends thought that he was dead, and so interred him without loss of time, through fear of contagion. The deceased, or rather the supposed deceased, had received a large sum of money, amongst which were a few banknotes, shortly before his attack; but the notes were not forthcoming. It was then remembered, that the unfortunate man had been buried in his breeches and dressing-gown—the same through fear of contagion. Permission to exhume the body was obtained, and the precious notes discovered in his breeches' pocket; but, alas! the unhappy proprietor was found turned on his right side, and, in despair, had eaten three of his fingers."

The above is related by the *Kamper Courant*, and the Dutch are a serious people; but, *Credat Judæus*. *Apropos* of premature interments I may notice briefly an excellent work by Dr. Bouchut, "On the Signs of Death," which has recently received a prize from the Institute.

Dr. Bouchut distinguishes the signs of death into two classes—the immediate and the remote. The immediate are those which indicate cessation of the functions of the heart, lungs, or brain.

The immediate signs connected with the heart—and these are infinitely the most important—are

Prolonged absence of the pulsation of the heart, or auscultation.

Cadaveric aspect of the face. Loss of transparency in the hand. Absence of bullæ and the inflammatory circle, after burning the skin.

Of these phenomena, cessation of the heart's pulse determined by auscultation, is the principal. According to the author, and to the Committee of the Institute, it is a *certain* sign of death. In all the experiments made on the subject, life was found to be irrevocably extinct, after the heart had ceased to beat for six or seven seconds. But, to avoid all error, the Committee propose extending the period to *five minutes*; and they also add, "Provided this absence of pulsation be immediately followed, if it has not been preceded, by cessation of the respiration, and of the functions of motility and sensation." This latter clause has been added to meet the observation of some medical writers, who pretend "that in yellow fever, thymic asthma, &c., it has been impossible to discover, with the stethoscope, for a long time, any pulsation in the heart, although respiration and other vital phenomena continue."

In addition to the proofs derived from experiments on animals, Dr. Bouchut shows clearly, that in all cases of apparent death—and particularly in those connected with asphyxia and syncope—the heart never ceases to beat for a moment. The pulsations are slower, but never completely suspended. This is demonstrated for the apparent death of new-born infants—for all kinds of syncope—for the most perfect forms of lethargy.

Having thus demonstrated, that we possess a certain sign of death, viz., absence of the heart's pulse for a few minutes, discoverable by auscultation, it becomes a matter of no importance to consider the accessory phenomena, derived from the state of the lungs or brain.

The same fact likewise points out the inutility of those mortuary houses in which bodies are preserved in Germany until the first signs of putrefaction set in.

Some interesting cases worthy of record have recently occurred in our hospital practice here. The first which I shall notice was one of

ŒDEMA OF THE GLOTTIS AND LARYNGOTOMY.

The patient, a female servant, 30 years of age, was exposed, while in church, to a cold draft of air. On returning home, she felt some pain in the throat, particularly on the left side; had frequent accesses of suffocation, and fever with headache. She was admitted into the Hotel Dieu on the following day; the symptoms were now much aggravated. The countenance was cadaverous, respiration difficult and sonorous, voice feeble but clear; frequent accesses of suffocation, which cause great anxiety to the patient, and are reproduced by every attempt at swallowing. Pulse 112, without much heat of skin. On passing the finger deeply into the fauces, an annular projection was very distinctly felt at the superior orifice of the larynx.

Although there was no immediate necessity for operating, M. Roux advised the performance of laryngotomy, because the surgeons would not visit the hospital again for twenty-four hours, and it was impossible to say that dangerous symptoms might not set in during that interval.

The operation was, therefore, performed on the spot. It gave immediate relief to the patient. In the evening, thirteen ounces of blood were taken from the arm by way of precaution; and from this time up to the eighth day, when the patient was convalescent, not a particle of medicine was administered, if we except an emollient enema on the fourth day.

The rapidity of the cure in this case, and the simplicity—indeed, one might say absence—of treatment after the operation, are points worthy of notice. An English surgeon might not have felt himself justified in having recourse to tracheotomy at so early a period of the disease; but the rapid convalescence was in all probability mainly due to this circumstance, inasmuch as the patient remained free from the pulmonary engorgement which generally sets in whenever the operation has been delayed in cases of this kind.

Another point to which I may briefly direct attention is, the extreme simplicity of the after treatment. The case, in fact, was left to nature, and proceeded to a perfect cure just as rapidly as if it had been treated on the most "scientific principles"—that is to say, with purgatives, acetate of ammonia, opiates, and the other ingenious modes of administering drugs, so familiar to the English school. It may be also well to observe, that no effort to vomit was excited by the contact of the finger with the epiglottis and upper part of the larynx, during examination of the throat. It would appear, that when the epiglottis is inflamed, it loses that special sensibility, in virtue of which vomiting ensues when the organ is touched.

GANGRENE OF THE SCROTUM—AUTOPLASTY —USE OF COLLODIUM.

Although gangrene of the scrotum, giving rise to more or less complete exposure of the testicles, has frequently presented itself to the practice of surgeons, few efforts have been made to remedy this distressing accident in a scientific manner. In some cases the whole of the front of the scrotum has been destroyed, and, as cicatrization advances, the wound contracts behind the testicles, thus increasing the exposed condition of these organs.

In such extreme cases surgeons have been usually content to leave the cure to nature, when the testicle is finally covered by a thin and imperfect cicatrix. M. Malgaigne, one of the most rising young surgeons of the French school, has acted differently. In two cases of the kind alluded to, he separated the adherent edges of the wound from the testicle, formed a cavity behind in what remained of the scrotum, and united the edges in front of the testicle with the twisted suture. These two cases were completely successful. The following case, somewhat analogous, is a striking example of the resources of surgical skill under the most unfavourable circumstances:—

A soldier of the 32nd Regiment was admitted into hospital with complete exposure of both testicles, the consequence of gangrene of the scrotum after small-pox. The wound was cicatrising, but the loss of substance had been so great, that the cicatrix, in contracting, pushed the testicles forward, and thus exposed them more and more every day. It was, therefore, resolved to imitate the practice of M. Malgaigne, and endeavour to unite the remnant of the envelope in front of the organ. The patient was placed under the influence of chloroform, and within a minute fell into a deep sleep. The skin was now separated from the lateral and inferior portions of the cicatrix, and the dissection carried back sufficiently to allow of the integument being brought forward so as to cover the testicle completely. The edges of the wound were then rendered smooth with the scissors, brought forward and united in front along the median line, by five points of the twisted suture. A small branch of the pudic artery was tied. The usual dressings, supported by a suspensory bandage, were next applied, and the patient replaced in bed. On the fourth day after the operation, it was found that the needles had cut through the skin; that the flaps showed no disposition to unite, and, moreover, were so attenuated as to prevent the use of diachylon straps. Under these circumstances, the Surgeon had recourse to the use of collodium. Two small pieces of linen, cut into the shape of two cutaneous flaps, were imbibed with collodium, and then applied along the external surface of the wound, on both sides, from above, downwards. Six short ligatures were then glued, in pairs, and opposite each other, with the same substance to the linen bands,—one pair just under the penis; the other at the middle of the wound; the third near its inferior angle. On tying together these ligatures, the edges of the wound were brought together, completely in front of the testicles. This apparatus was allowed to remain undisturbed for six days. On removing it, the flaps were found adherent to the subjacent surfaces, and also by their edges, except at the superior and inferior angles. Here were some exuberant granulations, which were touched with the nitrate of silver. A fresh dressing, similar to the former one, was now applied, and allowed to remain for four days longer. At the expiration of this period, the whole of the wound was completely united, with the exception of a few lines at the lower angle, and even this cicatrised on the thirtieth day. The scrotum then presented, in every respect, a normal aspect.

The practice adopted in the above case is well worthy of imitation, under analogous circumstances. It would, however, appear advisable to have recourse to the collodium at once, instead of wasting time by an endeavour to unite the edges of the wound with the twisted suture. In cases of this kind, the surface of the exposed testicle is almost always in a state of suppuration, and it is extremely difficult, if not impossible, to make the sound skin adhere to this suppurating tissue through the medium of suture.

GERMANY.

[From our Berlin Correspondent.]

The cholera returns have greatly diminished. But when we remember, that, in the present year, the disease having left Breslau and returned to it with increased virulence, we can scarcely venture to hope that Berlin has shaken off the scourge. The four provisionary Cholera Hospitals, however, are closed, we trust not to be re-opened. There is some talk, however, of erecting a permanent Cholera Hospital, people thinking that the disease, like democracy, can never be chased from the German vaterland. Among Medical men, those of the cold water establishment have suffered most severely. They inundated the newspapers with the wondrous results of hydropathy and their mode of treating cholera; but, alas! no less than eight of their number died of that disease.

The annual meeting of the German Naturalists lately occurred at Regensburg, in the Town-hall, where the Diet was held. The meeting seems to have given some uneasiness to the Government since they refused their usual contributions to its funds, hoping by these means to prevent social reunions and dinners, which might lead to speakings more plain than pleasant to their ears. Nevertheless, though the gaiety and *bon esprit* of former years were in a great measure absent, banquets did take place, concerts were given, and the excursions to the neighbourhood numerously attended.

In science nothing very great occurred. A paper on Climatization, by Professor Kolenati, of Prag, excited some attention from the theory he propounded, that men shed their skins as other animals their coats, and that like them, they assumed a thicker or a thinner covering—a natural skin he meant—according to the climate in which they resided. When this change is effected, man is said to be "acclimated."

In Saxony and Wurtemberg medical reform continues to be agitated, and new modes of teaching, examining and appointing, to medical situations under the Government to be proposed. It is demanded, that no "pures" shall exist; that all shall practice generally, and that medical men be allowed to dispense their own drugs.

Your readers will regret to learn, that the celebrated anatomist and physiologist Tiedmann, of Heidelberg, has retired from public life. Grief for the loss of his son, who, as commandant of the fortress of Radstadt during the revolution, was shot by the Government of Baden, has led to his retirement.

Busch, the well-known Professor of Midwifery, has been elected "Rector Magnificus" of the University of Berlin.

From Russia, we learn that Professorships of the Theory and Practice of Medicine have been founded in the University of Dorpat. The chairs are well endowed; and have also retiring allowances for the Professors, and pensions for their widows and orphans.

ON THE STRUCTURE OF THE LIVER. BY A. RETZIUS.

The chief results obtained may be summed up as follows: That the liver is essentially lobular, but

that the lobular form makes its appearance in several different stages of development and retrocession, with a blending of the lobules in conjunction with more or less regular development of the ramifications of the hepatic veins. What principally shows the presence of the lobular type is the constancy of the alveolar network of the biliary tubes. 2. That the biliary conduits, with their proper walls of basement membrane, are certainly tubes. Retzius has completely proved the presence of this membrane, in accordance with the description of Schröder van der Kolk, namely, as a simple membrane, which invests both the angular and round cells of the liver. It may be demonstrated, by removing from a liver first macerated in ether, and afterwards dried in extremely thin slices. These are placed in water to render them transparent, whereupon they exhibit the proper membrane of the finest network of the biliary tubes, in simple outline, enclosing the cells above mentioned. 3. Retzius was unable to discover any arterial net in the capsules of Glisson. —"Mueller's Archiv," 1849, No. 2, p. 169.

SCOTLAND.

[From our Edinburgh Correspondent.]

PROFESSOR WALSHE'S VIEWS.

We have felt much indebted to the *Medical Times* for putting into our hands the Introductory Lectures of Professors Walshe and Farre, at the opening of their respective schools. We have read, also, with interest, the Editorial Article on these two lectures in the last Number of the *Medical Times*. We are not all of one mind in Edinburgh on such subjects as are handled in these lectures. There is, however, a very general impression here, that the Medicine of the day expends its activity so largely on matters of detail, as very much to exclude discussions involving just conceptions of Medical Science, and the exact adjustment of the principles on which its improvement can be carried forward. We therefore, in general, hail the publication of these lectures as a sign of a growing attention to the means of ascertaining and making apparent to the Profession at large, the real position at present of Medicine as a Science and as an Art. In Dr. Walshe's lecture, there is little to which we cannot subscribe when we have fairly caught up the sense in which he designs his words to be understood; but we think, in not a few instances, he has set up a phantom for the purpose of cutting it down with effect. Again, we fear he has guarded himself too little against being misunderstood by the student, and being represented as considering physiology as either hurtful, or as affording no aid in the cultivation of Medicine. He admits, it is true, "that physiology may be considered as suggestive of points of inquiry in pathology, and as establishing a standard of reference for morbid conditions and processes." But this seems like a concession extorted from him; nor are the words in which it is couched like those of one who feels the real bearing of physiology on the cultivation of medicine. In reality, however, this admission is a sufficient ground for claiming his testimony to physiology being the essential basis of pathology. We should like to learn how any researches into the constitution of the blood in diseases could deserve the name of pathological, unless the physiological constitution of the blood, and all its variations within the limits of health, were previously ascertained. Nay, can we trust any pathological conclusions as to the peculiar alterations of the blood in diseases, unless the analyst be physiologist enough to determine the normal condition of healthy blood? Again, can auscultation or percussion indicate any pathological condition of the chest or abdomen, until the signs of the normal condition of these cavities have become known to the inquirer? Here, then, also, physiological must precede pathological observation; or this diagnostic pathology, like every other form of pathology, implies a previous acquaintance with physiology. If it be said that a man may be a discoverer in pathology without having been a discoverer in physiology—be it so—does this prove pathology to be independent of physiology? It amounts merely to this, that within certain narrow limits there may be a division of labour, so that, if a physiologist has previously determined certain facts, then the pathologist may proceed on these facts in his further inquiries; but here again the inseparable dependence of pathology on physiology meets us. In short, pathology is not inseparable from physiology by any absolute line of demarcation. Physiology is the science of life, and, therefore, in its strictest sense, it includes pathology. Under this view, medicine is merely a department of physiology. But, to waive this idea for the present, in all the pathological states of the living body, the physiological laws are still operating, only under a certain modification; and, therefore, unless pathology be confined to signify mere morbid appearances discoverable after death, physiology is always co-existent with pathology. One part of the admission made by Dr. Walshe in favour of physiology—namely, that physiology may be considered as suggestive of points of inquiry in pathology, is not a great concession. It is more true that physiology suggests many points for inquiry as regards the treatment of diseases; and it is less suggestive of inquiry in pathology, because, what is special in pathology mainly consists of facts, while its principles are, in general, merely modifications of the principles of physiology. Let Dr. Walshe lay down what he thinks the most correct view of the acts which constitute inflammation, and he will at once discover that he is all the while discoursing of a not very considerable modification of the normal or physiological capillary circulation. No doubt it is quite true, and in this we entirely agree with the learned lecturer, that the most exact knowledge of the normal capillary circulation does not suggest the knowledge of that modification of it which constitutes inflammation. For the discovery of what creates the difference between its normal form and the anormal form, termed inflammation, must be the result of a judgment founded on particular observation. But, on the other hand, the most patient observation and the most exact judgment will altogether fail to determine what inflammation is, unless the physiology of the capillary circulation be first made fully apparent; and it is manifest that the obstacle at present to a satisfactory account of the process of inflammation, is not so much the want of zeal in pathologists to observe the anormal state, as the want of power in physiologists to explain the essential nature of the normal capillary circulation. For though physiology may be cultivated without pathology, it is impossible to take a step in pathology without physiology.

The Professor, we make no doubt, conceives that he has admitted all that we say; but yet we cannot help repeating that his lecture leaves an impression on the mind, undesigned as it appears to be, that physiology is really of little moment towards the improvement of pathology. But there is one point in which physiology is of inestimable service which he leaves altogether out of view, and this we would try to explain. Neither physiology nor pathology can be cultivated to any extent by the mere observation of sensible qualities, as is the case with some parts of natural history. A very great part of pathological inquiry relates to the determination of sequences of action involving a judgment as to events standing to each other in the relation of cause and effect. To have imbibed the spirit of the laws of nature in the department under investigation is the only effectual preparative for the right exercise of this kind of judgment. Hence no man's authority has had any permanent weight in pathology unless his mind had become imbued with the spirit of the plan on which the animal economy proceeds in its normal state; that is, with the spirit of physiology.

Moreover, we cannot help thinking that the faults charged by Dr. Walshe against medicine, on the score of its use of physiology, belong less to our time than to past history. True, Dr. Forbes is of our time, and so is Liebig—but the latter can hardly be ranked in the Profession, and his views, as it appears to us, have seldom been rated beyond their real value, that is, as the ingenious speculations of a gifted chemist, which have served to direct the attention of physiologists and pathologists into new fields of inquiry. As to the use Dr. Forbes makes of the term physiological physician, of which Dr. Walshe complains, we think it is very pardonable, being satisfied that few things are more in accordance with the general laws of the animal economy than the principle involved in his observation, namely, "that a morbid condition, which may have been months or years in forming, can only be effectually or permanently removed by means which act slowly and for a length of time, not on one part only, but more or less on the whole system."

Again, we really do not think there is any particular disposition at present to foretell the phenomena and pathogeny of diseases, prior to experience, from the mere knowledge of the physiology of texture and function. And we are quite sure Cullen did not so produce his *Synocha*, the instance Dr. Walshe cites. The process by which Cullen obtained his synocha was quite the reverse; he found that the symptoms of an inflammation may be analysed into symptoms denoting disturbance of function in the affected organ, and certain pretty constant constitutional symptoms of a febrile character. He subtracted the local symptoms, and thus obtained a febrile state common to inflammations in general, and to this state he applied the name synocha. He defined this term under the head "Febres," side by side with hectic fever; and throughout his nosology, when he had occasion to refer to that train of constitutional symptoms, he found the convenience of expressing it by the single word "synocha," just as by "febris hectica," in other circumstances, he briefly denoted the train of constitutional symptoms put down in an adjoining paragraph. It is true that Cullen, while it is plain that this convenience was his main object in constructing the genus "synocha," does not expressly say, that synocha never is an idiopathic fever; nay, he gives instances from authors of what he considered to be true continued fevers of this type; and though his successor, Dr. James Gregory, was accustomed to remark, as Dr. Walshe says, that he had never seen this form of fever as an epidemic continued fever, yet many of us here are of opinion that a large proportion of the cases in our two last Edinburgh epidemics were properly referred to Cullen's synocha. But this is a digression.

We sincerely thank Dr. Walshe for the opportunity he has given us of talking on such subjects; and we would just advert, for a moment, to an error among the speculative in medicine at present to which, we think, the doctor has not adverted. It must be confessed that scientific medicine is cultivated with much assiduity, and, in a certain measure, with very great success, by the aid of minute physiological and pathological observations; and it is nothing more than reasonable to look forward to much progressive benefit, in the course of time, from this source. But the over-zealous partizans of this kind of inquiry look upon their method as too exclusively that by which the improvement of practical medicine is to be effected. They neglect, too much, what has been already done, and refuse to take the pains to incorporate their new views with what is valuable in the old, while they prematurely flatter themselves that the practice of medicine is soon to attain a rational or purely scientific basis, when, as they deceive themselves, the treatment will be at once suggested by the pathology of a disease.

We entirely agree with Dr. Farre as to the benefits which the microscope, under right management, is likely to afford to medicine. He has most properly qualified what he says of the expected light to be thrown on cholera by the microscopic discovery of its connexion with the presence of peculiar vegetable organisms; but we strongly fear he will have to put the Bristol microscopists, next year, in the same category in which he puts Dr. Ley's so ingenious theory of spasmodic croup.

APPOINTMENT.—On the 17th inst., Dr. D. Lewis, of Finsbury-place, was unanimously elected one of the Physicians to the Royal General Dispensary, Aldersgate street.

Complaints having reached us of the irregular delivery of the MEDICAL TIMES *in the country by the Booksellers and Newsmen, we state, for the information of our readers, that this Journal is always published early on Friday afternoon, so that it may reach the Provinces by post on Saturday morning.*

Correspondents are requested to address their Communications to "The Editor of the MEDICAL TIMES, *147, Strand."*

TO SUBSCRIBERS.

New Subscribers will oblige by forwarding their Names direct to the Office, 147, Strand, or to the News Agents or Booksellers. All Post-office Orders should be made payable to the Publishers, WM. S. ORR AND CO.

THE MEDICAL TIMES.

SATURDAY, OCTOBER 27, 1849.

IN the month of September, 1847, Mr. Synnot, of Cadogan-place, was summoned by Mr. Mills, the Deputy-Coroner for West Middlesex (Mr. Wakley's deputy), personally to appear at his Inquest, and to give evidence touching the death of a child which he, Mr. Synnot, had attended during its brief illness. Mr. Synnot had made a *post-mortem* examination of the body, and had discovered that the death of the child had been caused by three pieces of nut sticking in the bronchial tubes. The evidence which Mr. Synnot gave was most strictly medical; and it enabled the jury to return a very satisfactory verdict, and withal a very unusual one, namely, the true cause of death: At the termination of the Inquest Mr. Synnot demanded his medical fee; but Mr. Mills, actuated by some unaccountable feeling, refused to pay it to him, arguing that Mr. Synnot had merely been summoned as an ordinary witness. Upon this, Mr. Synnot very properly brought the matter before the Judge. It was tried in the Bloomsbury County Court, on Wednesday, the 1st of December, 1847; and his Honor, on advising Mr. Mills to pay the fee claimed by Mr. Synnot, said, that the Act on which Mr. Mills grounded his objections to pay had been entirely repealed by that of Vic. 1, cap. lxviii. sec. 2, "wherein it was expressly stated, that immediately an inquest terminated, all witnesses' and other incidental expenses shall be paid by the Coroner, who will be reimbursed by the Justices at Quarter Sessions, the different sums allowed being stated therein," among which was—medical fee, 1*l.* 1s. Only the last Trinity Term, Lord Denman had tried a case heard on a mandamus against the Justices of Caernarvon, who refused to allow a Coroner for a medical witness; but whom, by the decision of his Lordship, they would be compelled to pay. In fact, according to the Act quoted, they had no discretion in the matter, and he was of opinion, that it was of no consequence what summons a medical man received, for if even he was in a room, and should unexpectedly be called upon to give evidence, he could substantiate his demand. And (continued the Judge) it would be a very bad precedent to confirm the non-payment of a Medical man summoned as a witness, and great difficulty would, by so doing, arise in obtaining his attendance. This action, instead of being brought in "tort," has been instituted as though a contract existed, through which technical mistake the plaintiff is liable to be non-suited; *but he can, of course, recover by obtaining a mandamus*, and I, therefore, should advise you, Mr. Mills, to take the case into your own hands, that is, to pay the money demanded by Mr. Synnot."

A second case, of a somewhat similar character, has just occurred within the jurisdiction of the same Coroner. An inquest was held at Hampstead, on the 24th of August last, by Mr. H. Membury Wakley, the Deputy-Coroner, and, at that inquest, he required the evidence of Mr. Lord, the medical attendant of deceased, but instead of issuing a written summons to the Medical witness, merely sent off an officer to him, with a request that he would attend immediately. Mr. Lord accordingly made his appearance; and, notwithstanding that the deceased died from cholera, for such was the verdict, and that there was not a shadow of suspicion of any kind connected with the case, yet the Coroner deemed it necessary to institute an inquiry into the line of medical practice adopted by Mr. Lord. He, however, refused to answer the questions, believing them to be irrelevant, and the Coroner, therefore, adjourned the Inquest, in order that another surgeon might make a *post-mortem* examination of the body. When the inquiry was at an end, Mr. Lord advanced and demanded the fee which is allowed by law to a medical witness. The Coroner, however, refused to pay it, acting, as he said, on *principle*; upon which Mr. Lord retired, and, on the 16th instant, sought to recover the fee by summoning Mr. Wakley before Mr. D. C. Moylan, at the Westminster County Court; and his Honor having asked Mr. Wakley what line of defence he meant to take, the latter replied, that he should oppose the claim upon two grounds—

1st. That the summons from the County Court was informal, inasmuch as it did not contain his Christian name; it was, moreover, addressed to the Coroner, whereas he was but the Deputy-Coroner; and it was sent to the Coroner's office, and not to his residence.

To which the Judge replied, that, by an Act of Parliament, the plaintiff was bound to state in the summons the Christian and surname, the occupation and residence of the defendant; and, if he failed in these respects, the case must fall to the ground.

2ndly. Mr. Wakley said, that he was not bound to pay Mr. Lord his fee, inasmuch as he had not issued a written summons to the plaintiff.

Upon which his Honor remarked, that, according to the Act of Parliament, it was essential that a summons should be issued by the Coroner before a party could claim a right to the fee for his attendance. In the present case, no summons had been issued; and, therefore, the plaintiff must be non-suited; but he would not allow the defendant (Mr. Wakley) his costs.

We refrain from making any comments on these cases, notwithstanding that the animus which has been exhibited in them is most unjust and most unprofessional. We may say, too, and it is a remarkable circumstance, that Mr. Wakley is, as far as we have been enabled to learn, the only Coroner who has, through his officials, had to play so disagreeable a part in a court of justice. Other Coroners, however, may, and probably will, take advantage of this example, so unfortunately placed before them by a medical colleague, and our Professional brethren may have much difficulty in securing the fees, small as they are, which are allowed to them by Acts of Parliament; consequently, we think it right to place before them, which we do in another part of our Journal, the entire Act relating to medical witnesses, whereby they will be enabled to perceive the precise position in which they are placed with regard to Coroners.—[See p. 347.]

Again, an Act was passed in the first year of Victoria, cap. lxviii., in the second section of which it is ordered thus :—

And be it enacted, that so much of the said Act passed in the last session of Parliament as directs the Coroner to make out an order on the churchwardens and overseers of the parish in which any death shall have happened, for payment of the remuneration or fee payable under the provisions of that Act to any medical practitioner, and as directs such churchwardens and overseers to pay the same out of the funds collected for the relief of the poor of such parish, shall be, and the same is hereby repealed, and in lieu thereof the Coroner shall, immediately after the termination of the proceedings at any inquest, advance and pay such remuneration or fee to every medical witness summoned under the provisions of the said Act, and the amount thereof shall be repaid to the said Coroner in manner hereinafter mentioned."

As to the form of summons which is usually issued, we may remark, that they are rarely, if ever, legal, inasmuch as they are not worded after the manner of schedule A.

A non-medical summons, as given by Jervis in his Work on the Office and Duties of Coroners, runs thus :—

—— *to Wit.*—Whereas, I am credibly informed, that you can give evidence on behalf of our Sovereign Lady the Queen, touching the death of R. F., now lying dead in the parish of ——, in the county of ——: these are, therefore, by virtue of my office, in Her Majesty's name, to charge and command you personally to be and appear before me at the dwelling-house of ——, known by the sign of the ——, in the said parish of ——, at six of the clock in the evening, on the day of —— instant, then and there to give evidence and be examined in Her Majesty's behalf before me and my inquest, touching the premises. Hereof fail not, or you will answer the contrary at your peril. Given under my hand and seal, this —— day of ——, one thousand eight hundred and ——.

"C. D., Coroner, L. S.

"To A. B., C. D., &c."

Finally, we may mention that, in case the summons received is not altogether legal, the County Court is not the place for the recovery of the fee, inasmuch as this Court merely presides over matters of contract, and the Case will fail if the contract is not, in every sense, a legal one. The claimant, however, can recover by obtaining a *mandamus* against the Coroner.

THE PIMLICO CATASTROPHE.

THE melancholy accident, by which five lives have been sacrificed in a sewer, is suggestive of so many points of comment, both hygienic and general, that we should ill acquit ourselves of the responsibilities we are under, as Medical Journalists, by failing to notice it at the present time.

The idea of five human beings dying, like

dogs, in a ditch, is, abstractedly considered horrible in the extreme; nevertheless, if proper use be made of the facts eliminated by this catastrophe, we may glean such an amount of truthful indications for future guidance as shall sanctify the accident as a holocaust to the health of millions, and temper our regrets with hope.

Truth is frequently invisible, except in extremes. The gradual poisonous agency of sulphuretted hydrogen gas, when sparingly evolved from the sewers and gulley-holes of this vast metropolis, might have been denied as strenuously hereafter as it had been heretofore; the experiments of the toxicological chemist on this subject might have again been set at nought casualties traceable to this agency might have again been utterly ignored; suspicious deaths again referred, without due investigation, to the operation of natural causes; and, eventually, the whole question at issue lost in the studied mystycism, and angry recriminations of ignorant and interested "Boards." A palpable fact, however, so horrible in all its circumstances, as the one to which we advert, cannot fail, we imagine, to leave some impress upon the susceptibilities of a Commission of Sewers —cannot fail, we should hope, to induce those functionaries to whom the charge is delegated of caring for the public health, to be less sceptical than they have been to the adverse influences, identical in kind, though differing in degree, to the one brought home, by the Warwick-street tragedy, to the level of their comprehension. Medical chemists have long been aware that sulphuretted hydrogen gas is one possessing, even when in a diluted state, a wide sphere of fatal influences. Even an atmosphere, which contains an amount of this gas so insignificant that the olfactory organs are unable to indicate its presence, is known to be capable of inducing violent headaches, palpitations, and other symptoms, which, if extended over a sufficient period, would infallibly be fatal. In a more dilute condition, if this gas be taken into the lungs, or applied for a sufficient length of time to the skin, medico-legal inquirers have too long been cognisant of the fatal result to require the evidence of an accident. Nay, other individuals there have been, and amongst them some of the greatest luminaries of our Profession, who have attributed a still larger sphere of noxious influences to the gas in question, and have believed it to be the direct cause of fevers of a most malignant kind. Thus, the malignant fever of the western coast of Africa has been attributed to the development of this gas from the decomposition of sulphates, by the agency of organic matter with which they are brought in contact; and one link in the chain of evidence between the effect and its presumed cause is supplied by the invariable existence of free sulphuretted hydrogen in the waters, both fresh and oceanic, of these regions.

We may or may not be converts to the abovementioned theory. The question is totally beside the bearing of the proposition which we are about to submit; namely, that sulphuretted hydrogen gas being generated very largely in sewers, and being known as a most poisonous gas, it is incumbent on those who are guardians of the public health to provide adequate means for carrying it harmlessly away. For, whether it be a definite and immediate cause of specific maladies or not,—every one competent to offer testimony in the matter will admit, that its diffusion in the atmosphere of which we breathe cannot fail to lower the stimulus of life, and thus to break down the barriers of health against disease.

Whilst the inquest on the five unfortunate victims of the sewer accident was yet incomplete, we could not help feeling, that the surveyor, under whose directions the exploration was made, should have reflected more deeply than he did on the peculiar conditions of the operation in question. The fatal tunnel did not terminate, as usual, in an open mouth, but against a brick wall, with which this mouth had been occluded. Hence, it must necessarily happen, that any gas which might have been there present, could not do otherwise than linger in the drain. To have sent men down into a sewer thus occluded, we could not but designate as a very grave oversight, for which the surveyors of the Commission of Sewers must be held responsible. The verdict of the Coroner's Jury has since confirmed our view.

We feel it our duty also to reprehend the carelessness, apathy, or whatever feeling it might have been, by the operation of which it was permitted the ill-fated Mr. Wells to remain half an hour without medical attention. Apparently dead though he might have been, we know, that, in cases of asphyxia, the patient should not precipitately be considered as lost, but that attempts at re-animation should be instituted; invariably and on the instant. Neither is it creditable, in these days, for a liberally educated member of the Medical Profession to testify, that in his belief the blueness of surface of such as die from the breathing of sulphuretted hydrogen is due to the reaction of that gas on iron in the blood. In the first place, sulphuretted hydrogen does not turn iron solutions black or blue, the metal in question being a well-known exception to the general rule; and, in the second place, iron as it exists in the blood is well known (owing to some peculiarity of combination) to be unaffected by any gaseous or liquid test. We forbear to expatiate further on the lamentable occurrence at the present time. It is one which presents, under an aspect of harrowing misery, truth in an extreme manifestation. Well will it be for the sanitary interests of the thousands congregated in this vast metropolis, if such an extreme manifestation shall not have occurred in vain. Well will it be, if the manifestation of this poisonous agency, killing with sudden deathstroke, surely and at once, shall cause our legislators to reflect on the amount of physical prostration, illness, and lingering death which the same agencies day by day produce, when in a more diluted form; results long made known to the educated inquirer by the evidence of philosophy, but only visible to the more stolid comprehensions of Commissions and Boards by a sudden catastrophe, such as the one we have described.

THE FORTHCOMING REPORT OF THE CHOLERA COMMITTEE OF THE COLLEGE OF PHYSICIANS.

We last week informed our readers, that we hoped, in our present Number, to be able to lay before them an abstract of the Report of the Cholera Committee of the College of Physicians. We are sorry that an unavoidable delay in preparing the wood-cuts has prevented the appearance of that Report so soon as we expected. But, in the meantime, we may state the following as the chief results obtained by the labours of that Committee.

The "Cholera fungi" do not exist in the waters of a large number of the districts in which Cholera prevails.

The "Cholera fungi" cannot, by the most careful examination, be detected in the air of many rooms inhabited by Cholera patients.

"Cholera fungi" are constantly to be found in the stools passed by patients labouring under other diseases than Cholera.

"Cholera fungi" are occasionally to be found in healthy stools.

The bodies which have been called "different forms of the development of the cholera fungus," are in quality the most dissimilar in their origin and chemical constitution.

Should the report contain the details of facts which bear out the above statements, the thanks, not only of the Profession, but of the community at large, will be due to the gentlemen composing the Cholera Committee, for their zeal and energy. The names of the Secretaries, Drs. Baly and Gull, are sufficient guarantee that the material placed at the disposal of the Committee will be used to the greatest advantage.

THE APPOINTMENT OF SURGEON TO PRINCE ALBERT.

The appointment in the Household of H.R.H. the Prince Albert, lately vacant by the death of Mr. Aston Key, has been bestowed upon Mr. Fergusson, Professor of Surgery in King's College.

The great body of the Profession, we feel assured, will agree with us, that a better choice could not have been made. Mr. Fergusson has attained — and that entirely by his own merits — the foremost rank in his department of the Profession; he is as much respected in his private character, as distinguished by his professional acquirement; and, while one and all will unite in congratulating him upon the eminent success that has marked his career in life, none will say it is undeserved, or that others would have occupied more worthily his high position.

THE OPERATIVE SURGERY OF JOHANN FRIEDRICH DIEFFENBACH.

Edited by
J. STEVENSON BUSHNAN, M.D.,
Fellow of the College of Physicians of Edinburgh;
And
ALEXANDER URE, Esq.,
Fellow of the College of Surgeons of England, and Surgeon to the Westminster General Dispensary, &c.

(Continued from page 310.)

OF TYING THE COMMON CAROTID ARTERY.

This operation was performed by Sir Astley Cooper in the year 1805; since then repeatedly by different surgeons, myself among the number. Both carotid arteries were successfully tied by Macgile within the space of a month.

The patient is to lie in a horizontal position, with the chest and head moderately raised. A cushion placed behind the neck, so as to extend it as far

as circumstances will permit: This is one of the most important preliminaries.

Cooper makes an incision through the skin and platysma-myoides, from two to three inches in length, along the inner margin of the mastoid muscle, to within an inch of the sternum. Rust and Von Graefe carry it rather further down. Bujalsky commences the incision superiorly rather more inwards. Langenbeck terminates the incision by the middle crico-thyroid ligament. On penetrating the space between the mastoid and sterno-hyoid muscles, and clearing away the cellular texture with the finger and handle of the scalpel, the omo-hyoid muscle is found crossing the great vessels of the neck. This, together with the thyroid gland, is to be drawn inwards, and then an opening carefully made into the common cellular sheath which surrounds the jugular vein, par vagum, and carotid. The jugular vein being drawn outwards, the proper sheath of the carotid is to be opened, the artery insulated, and engirt with the thread. The par vagum, situate between the jugular vein and the carotid artery, is to be shunned in applying the ligature. (a.)

Zang cuts between the two divisions of the mastoid muscle. The incision, from two to two inches and a half long, passes along the outer margin of the sternal portion, and terminates a quarter of an inch above the clavicle. The omo-hyoid muscle is to be drawn upwards and backwards, the thyroid gland inwards. The remainder is as in the other modes of operating. (A line drawn from the sternal end of the clavicle to the mastoid process indicates the direction of the carotid.—A. U.)

OF TYING THE SUPERIOR THYROID ARTERY.

The patient is placed upon an operating table, with the chest and head elevated, having a small round cushion under the nape, to throw the throat forward. The incision begins under the angle of the lower jaw, rather towards the outer side, and courses downwards along the inner border of the mastoid muscle. As soon as the platysma myoides and fascia are cut through, a portion of the cellular texture is taken up with forceps, and removed with a few horizontal touches of the knife. The artery, after being properly insulated, is tied. Care must be taken to avoid injuring a branch of the glosso-pharyngeal nerve. The operation may have to be modified from the altered position of the vessel in the instance of bronchocele. Here it is expedient to incise only where pulsation can be felt. Walther and other surgeons commence the incision in the interspace between the os hyoides and thyroid cartilage, and continue it for three inches down towards the sternum, by the inner side of the mastoid muscle. The success which has attended that eminent surgeon's operations for bronchocele is the best proof of the value of this method.

OF TYING THE LINGUAL ARTERY.

The patient is placed as in the operation of tying the carotid artery, with the neck extended, and the face turned to the opposite side. The cutaneous incision traverses the space between the os hyoides and edge of the lower jaw, but rather nearer the former, and is prolonged in the track of the artery from two to two inches and a half outwards, and somewhat upwards, beginning at the mesial line of the neck. After the skin and platysma myoides are divided, the facial vein is to be drawn aside, the cellular sheath of the submaxillary gland opened, and the gland, digastric, and stylo-hyoid muscles a little upraised; the hyoglossus muscle thus brought into view, is cut across upon a director insinuated beneath, whereupon the artery is laid bare and tied.

According to the method of Bell and Wise, the patient is seated with his head leaning back upon the breast of an assistant, who also fixes the lower jaw. The first incision, which goes through the skin and platysma myoides, begins over the body of the os hyoides, and extends for the length of two inches towards the mastoid process; the vein lying upon or beneath the fascia is to be drawn aside or cut across, and then the fascia divided in the line of the cutaneous incision. On drawing the posterior belly of the digastric muscle downwards and outwards with a blunt hook, the lingual artery can be felt upon the genio-glossus muscle, and fairly exposed by cutting through a few fibres of the hyoglossus muscle. Some twigs of the lingual nerve, and the contiguous thyroid artery are to be shunned.

Dieterich's plan deserves the preference, as being the most easily accomplished. The first incision begins three lines from the margin of the lower jaw, and is continued as in the operation upon the internal carotid. The digastric and stylo-hyoid muscles having been exposed, are to be drawn either downwards or upwards together with the lingual nerve, whereupon the lingual artery is seen coming off from the external carotid, with the lingual vein alongside. The vein is to be drawn upwards, the nerve downwards, and the artery tied.

The ligation of the lingual artery has been advised in hæmorrhage from the tongue, cancer of that organ, and the like. But as the tongue can be got at more readily through the mouth, the operation is not generally approved.

OF TYING THE TEMPORAL ARTERY.

This is a very simple matter, inasmuch as the pulsations of the vessel can be distinctly felt on account of the subjacent bone. The artery is most readily exposed by means of an incision made directly over the zygomatic arch. I have frequently tied the artery for parenchymatous bleeding, for punctured and lacerated wounds, as also for false aneurism. Dieterich and Manec recommend the incision to be made a quarter of an inch distant from the tragus, and to extend one inch directly upwards. The artery is to be separated from the vein, and tied above the origin of the auricular artery.

OF TYING THE OCCIPITAL ARTERY.

The cutaneous incision begins half an inch above the mastoid process, is prolonged in the direction of the fibres of the mastoid muscle, so that it passes close under the mastoid process. Skin, fat, and fascia, being divided as far as the cellular connexion of the above muscle with the splenius, the occipital artery is brought into view; the veins, both above and below, are to be respectively drawn aside; the artery is to be then insulated and a ligature applied (Dieterich). According to Manec, the first incision commences half an inch behind and below the prominence of the mastoid process, and an inch slantwise upwards and backwards through the skin, and tendinous aponeurosis of the sterno-mastoid muscle. Then the surgeon feels for the base of the mastoid process under the upper edge of the wound. He next divides the splenius capitis in the direction of the cutaneous incision, and arrives at the artery two lines below the digastric fossa. The former is the more eligible operation of the two.

OF TYING THE POSTERIOR AURIS ARTERY.

The tying of this artery is unattended with any difficulty from its superficial situation and sensible pulsation. I have done it repeatedly for wounds and for pulsating tumours of the ear. The cutaneous incision runs behind the flap of the ear downwards, along the margin of the mastoid process, the extent of an inch. The deeper incision severs the fat and fascia. The artery is perceived in the middle, between the border of the parotid gland in the lower angle of the wound, and the retrahens aurem muscle.

OF TYING THE ARTERIA INNOMINATA.

This artery was tied, for the first time, by Dr. Valentine Mott, in the year 1818; by Von Graefe in 1821; and by Arendt in 1828. Von Graefe directs the patient to be placed on his back upon the table in such wise that the head hang somewhat backwards. An incision is to be made on the right side through the integuments, two inches and a half long, by the inner margin of the sterno-mastoid muscle, as far as the sternal end of the clavicle. In the deep space between that muscle and the sterno-hyoid muscle lies the carotid. This serves as a guide to the trunk of the innominata, which has the trachea close by to the left, and somewhat behind. The point of the left index finger reposing on the vessel, acts as a conductor to the aneurism needle, by which the thread is conveyed round the vascular trunk from within outwards, as near its middle as possible, in order to shun the recurrent nerve. Bujalsky recommends as a means of more readily getting at the vessel, to make the cutaneous incision rather more to the inner side over the sterno-hyoid muscle, and to divide the latter obliquely together with the subjacent sterno-thyroid muscle.

OF TYING THE SUBCLAVIAN AND THE AXILLARY ARTERY.

The operation may be performed in four different places, according as the ligature will admit of being applied, low down, or high up. The lowest point is the axilla, the next is under the clavicle, above this bone; and lastly, at the tracheal end of the scalenus muscle.

1. *Ligation in the Axilla according to the method of Lisfranc.*

This is the most eligible, but to be undertaken only, when the wound or aneurism is in the upper fourth of the brachial artery. The patient is laid upon the opposite side, the hand elevated till it rest on the head, and supported in that situation. An incision three inches long is made through the tense skin of the axilla in the course of the pulsating artery. The edges of the wound are to be drawn apart with retractors, and the cellular texture separated and removed with the knife, whereupon the axillary vein and brachial plexus, of which the principal nerve is the median, are disclosed to view. The axillary artery lies behind. After having been insulated, and brought forwards with a blunt hook, it is to be tied below the spot at which the subscapular, the anterior, and posterior circumflex arteries are given off.

In the instance of punctured or incised wounds contiguous to the axilla, with lesion of the artery, where much blood is effused, coagulated, and stagnant, from provisional compression, I have been enabled to tie the artery more conveniently by following the tract of the inner margin of the biceps, than by the higher incision. Langenbeck has operated in the same way.

[By dividing the axilla into three equal portions longwise, and making an incision of three inches at the junction of the superior and middle thirds, the surgeon will expose the external cutaneous, then the median nerve, behind which lies the artery.—A. U.]

2. *Of Tying the Subclavian below the Clavicle.*

The patient is placed as above. An assistant standing on the opposite side compresses the artery in the interspace between the clavicle and acromion with his two fingers bent like hooks. An incision, four inches long, by the lower margin of the clavicle, divides the skin and platysma myoides, the cephalic vein at the border of the greater pectoral muscle being left untouched. A cut into the edge of this muscle brings the lesser pectoral into sight, and which crosses the outer margin of the wound. The artery may then be felt at the upper border of the clavicle, having the brachial plexus to its outer, the subclavian vein to its inner side. The intervening cellular texture having been removed, the artery is secured with a flat blunt hook, the thread passed round with an aneurism needle, and tied.

According to Keate, the cutaneous incision is to be made a quarter of an inch below the clavicle, carried slantwise upwards and downwards towards the point of the coracoid process, then the half of the clavicular portion of the greater pectoral and the tendinous portion of the lesser pectoral muscle cut across, the arm next elevated, the brachial plexus and axillary vein drawn aside with blunt hooks, and a ligature put round the artery. This method is tedious, from the amount of dissection involved, and from the operator having to pause to take up the external thoracic artery, which is inevitably wounded. It is followed by Rust, Zang, and Bujalsky, who, however, place the arm by the side, and tie the artery in the outer part of the wound. By making the incision a finger breadth lower, as Dupuytren was wont, the thoracic arteries and veins, and the acromial artery, run the risk of injury.

Lisfranc directed the arm to be lifted upwards and backwards; the cutaneous incision to extend

(a.) As a general rule in tying arteries, the director or aneurism needle ought to be introduced so that its point shall be always on the opposite side from the vein.—A. U.

three inches, beginning half an inch below the sternal end of the clavicle, and to pass between the sternal and clavicular slips of the greater pectoral muscle. The arm is then to be brought near the body. The artery lies covered by the vein at the sternal third of the clavicle.

According to Delpech, the cutaneous incision is to run between the greater pectoral and deltoid muscles, commencing at the upper margin of the acromial end of the clavicle, and proceeding along the inner side of the arm. In cutting deeply, the cephalic vein must be shunned. The artery with the brachial plexus is then to be drawn a little forward, insulated, and tied. This method is commendable, save the incision of the pectoral muscle, to which Dermott objects.

3. *Of Tying the Subclavian Artery above the Clavicle.*

The method of Zang is, perhaps, the most eligible. The incision is made in the middle of the triangle formed by the posterior belly of the omo-hyoideus and the posterior margin of the mastoid muscle. It commences at the outer border of the mastoid muscle, two inches above the clavicle, and extends outwards and downwards to the middle of the said bone. The artery is to be detached from the surrounding nerves, and tied, avoiding the transverse artery of the scapula.

Von Graefe made an incision from the posterior margin of the clavicular slip of the mastoid muscle along the collar-bone. Then he sought with his finger the scalenus anticus, and cut it across. The subclavian artery will be found running slantwise, covered with loose cellular texture, having anteriorly the subclavian vein and transverse artery of the scapula. Dupuytren adopted the same procedure.

According to Langenbeck, the shoulder is to be depressed, and an incision running parallel with the clavicle made over its middle. The external jugular vein is to be carefully shunned. On penetrating to the scalenus anticus muscle, the transverse artery of the scapula and the transverse of the neck are to be avoided. The artery will now be felt pulsating in the triangular space between the first rib, the scalenus anticus, and omo-hyoideus muscles. Above and upon it lies the brachial plexus, and at its inner side the subclavian vein.

According to Lisfranc the incision is to begin at the posterior border of the mastoid muscle, and to run for three inches above the clavicle towards its acromial end. The tubercle of the first rib being ascertained, the artery can be at once felt. The brachial plexus is situate further backwards, and outwards. (The tubercle referred to is upon the inner border of the first rib, and forms the point of insertion for the external margin of the scalenus anticus muscle. The subclavian vessels slide over the smooth depression upon the external surface of the rib immediately outside of the tubercle. Malgaigne states, that in a well-made adult person, reckoning the length of the clavicle at six inches, the artery, in its passage over the first rib, would be found at twenty-eight lines from the sterno-clavicular articulation, four lines more outward than the external third of the clavicle; it would, therefore be situate about the middle of Lisfranc's incision.—A. U.)

According to Bujalsky an incision two inches and a half long is to be carried from the fore end of the collar-bone along the hinder margin of the mastoid muscle. Then, the latissimus colli and subjacent fat, the superficial cervical veins, and a nervous twig from the fourth cervical, and the omo-hyoideus muscle, are to be divided, whereupon the scalenus anticus is seen under the lymphatic glands, with the artery to its outer side. This method is not so eligible as the preceding.

4. *Ligation of the subclavian artery at the tracheal end of the scalenus anticus muscle.*

According to Colles and Sir Astley Cooper, a horizontal incision three inches in length is to be made immediately over the sternal end of the clavicle, and then the clavicular end cut across. The cellular texture is to be separated with the handle of the scalpel as far as the scalenus anticus muscle, and search made for the artery at its outer border. In order to effect ligation below the exit of the vertebral and inferior thyroid arteries, the surgeon must keep to the outer side of the subclavian. The pleura is to be shunned in tying the noose. Dieterich advises the cut to be made more inwards, and both insertions of the mastoid muscle to be severed. The last is also Hodgson's suggestion, who traces the carotid up to the trunk of the innominata, and then ties the subclavian close by.

King, in order to save the mastoid muscle, directs the incision to be made as in the operation upon the arteria innominata. The artery is to be discovered between the windpipe and the scalenus posticus muscle. The par vagum is to be pushed aside inwards, the phrenic nerve outwards. In tying the left subclavian, he makes the incision by the right mastoid muscle, between the sterno-thyroid muscles; he then passes to the left from the trachea to the left carotid, and from hence to the subclavian, which is to be tied at its origin, taking care not to injure the thoracic duct. This is not a very available method.

Dieterich's procedure for tying the left subclavian artery is manifestly superior. At the inner border of the mastoid muscle an incision is to be made two and a half inches long, which is to commence at the sternum; then a transverse incision is to be carried outwards from the lower angle of the wound, whereby the sternal portion is at the same time separated. The mastoid muscle is to be drawn outwards, the sterno-thyroid inwards. The internal jugular vein, the carotid artery, par vagum, are to be detached and drawn outwards with retractors, after which the subclavian is perceptible in its cellular sheath. This is to be opened at the inner side, as the thoracic duct lies to the outer. The thread is next to be placed round the artery.

REVIEWS.

On the Nature of Limbs. A Discourse delivered on Friday, February 9, at an Evening Meeting of the Royal Institution of Great Britain. By Richard Owen, F.R.S. London: John Van Voorst, Paternoster-row. 1849.

But a few years ago, and it was the fashion to treat transcendental anatomy with open ridicule, or secret contempt. Some wild enthusiasts, for the most part Germans, had mingled anatomy with their dreams, and, as the untutored Indian recognized his deity in the clouds and winds, so they saw vertebræ and ribs in everything they examined. Happily, the new delusion was confined to a few mystics. Moreover, it required intense study, and offered no personal advantages to its cultivators; hence it was not very likely to be contagious. Otherwise, it was a hurt and detriment to the true science; and threatened to be, as it were, the alchemy of anatomy.

Much of this disparagement was no doubt owing to the particular word chosen to designate the alleged new study, than which there could scarcely have been a more unfortunate selection. "Transcendental anatomy" did seem a somewhat inflated term, and, so far, an objectionable one. Far from being the logical *differentia*, it had the singular demerit of not even expressing a quality, but rather the effect of some quality on the human mind. And although, in the estimation of its cultivators, it transcended all other varieties of anatomy, yet this was a feature too common to all pursuits to deserve much reliance. The honest currier in the besieged city firmly believed in the transcendental virtues of leather.

And it is but fair to admit, that in the subject itself, as then treated, there was a great deal to excuse, if not to justify this low estimate. Not only were those analogies which formed the staple of the science often fanciful and overstrained, but the language employed added to this obscurity; the same words being often used in such a manner as to imply, not so much likeness of the things compared as identity: an identity so far from existing, that it reflects considerable astonishment as to the sense which some authors attached to these terms.

But, while the time for ridiculing transcendental anatomy, if it ever existed, has long passed, so these, its earlier defects and hindrances, have also disappeared. It no longer demands separation, or affects a diguified exclusion from anatomy generally. If it have any especial claims they are these very intrinsic ones, that it is comparative anatomy in the highest sense, in the extent and number of its comparisons, and in the magnitude and importance of their results.

The Author of this book is everywhere known as an indefatigable anatomist, in whom observation and deduction are found in rare and fruitful union. But, in spite of his deserved fame and position, the very elaborate character of his works has probably hindered their receiving the attention they merit; since they demand a fixity of thought commensurate with the extent and depth of the subject. So little are these matters studied in England,—so completely has the art of anthropotomy usurped the place and title of the science of anatomy, that we doubt whether there are ten men in all London who have ever read Professor Owen's invaluable works, or could even describe, off-hand, the skull of an osseous fish. The parts of hernia and the origin and insertion of the biceps appear to constitute the ordinary limits of our knowledge; while, in rare instances, a sharp knife, a peculiar vision, and a turn for personal invective, enable us to invent new fasciæ and nerves, and shine forth as original discoverers. That large branch of anatomy which is investigated by the aid of the microscope has, it is true, an immense number of cultivators, whose industry is praiseworthy, albeit their zeal is scarce according to knowledge. But in the midst of all this, it behoves us constantly to recollect, that great as is the light shed by that important instrument, still, after all, it is but an auxiliary, and one which, as in its very nature, it requires the scalpel as a preliminary, so, therefore, it can never supersede it. This comparatively languishing state of comparative anatomy, the present work seems at least partially intended to meet. It forms a simple, philosophical, and attractive introduction to the anatomy of the skeleton; while it affords a very sufficient basis for many of the most important deductions which the whole range of the science affords.

The selection of the limbs for the subject of the discourse is peculiarly happy: since it not only offers the most striking comparisons, and the widest series of adaptive modifications, but it has the further advantage of insuring that every one comes to it with some preparation; since every one possesses a knowledge of their exterior form, and the more important of their articulations and movements.

But not only is this little book to be regarded as an introduction to the study of philosophic anatomy; it may also be viewed as to a great extent epitomizing the main principles of the science. The Author has especially laboured, and, we think, with no small success, to establish and formally enunciate one of the chief elements of that mysterious, and, to a thinking mind, awful law,—the oneness of organization. He believes that, by carefully comparing these parts of the bony framework of vertebrate animals, we may find evidence that they are all constructed upon a common plan, to which they conform, independently of common purpose, and from which they do not deviate, however devious their particular office.

The Author rests the existence of this plan mainly upon the fact, that, while in human contrivances,

which are merely special adaptations, we find the greatest diversity of means, in the limbs of animals we find a singular conformity; and that this conformity, not being required by them, is so far independent of them, and can only be attributed to an identity of plan, which exceeds or persists beyond the similarity of their function.

The first and most obvious objection to this statement is one which we feel bound to notice from the ease with which it may be raised by the most superficial, and the difficulty of its complete refutation. It may be asked by some,—"Does not this argument involve a *petitio principii*? Are we not justified in presuming, that, where the plan is one there is also a certain similarity of purposes, however different in appearance these may be? Is it not probable that the similarity of the limbs of these animals may *resemble* the similarity of their minute structure in being the result, not so much of an adhesion to an arbitrary plan, as of the adaptation of all these instruments to common physiological exigencies of nutrition and growth? And, in this way, may they not constitute a more recondite, but not less real, instance of adaptive modification, which would argue a common, but still a final cause?"

It is difficult to answer these questions with a decided negative. Perhaps, in the present state of our knowledge, it is impossible to do so. But the first objection, which would make similarity of purpose the cause of similarity of plan, is thus ably confuted by the Author.—(Page 39.)

"I think it will be obvious, that the principle of final adaptation fails to satisfy all the conditions of the problem. That every segment, and almost every bone which we possess in the human hand, should exist in the fin of the whale, solely because it is assumed that they were required in such number and collocation, for the support and movement of that undivided and inflexible paddle, squares as little with our idea of the simplest mode of effecting the purpose, as the reason which might be assigned for the great number of bones in the cranium of the chick, viz., to allow of the safe compression of the brain case, during the act of exclusion, squares with the requirements of that act. Such a final purpose is, indeed, readily exercised and admitted in regard to the multiplied points of ossification of the skull of the human fœtus and their relation to safe parturition. But, when we find that the same ossific centres are established, and in similar order, in the skull of the embryo kangaroo, which is born when an inch in length, and in that of the callow bird, which breaks the brittle egg, we feel the truth of Bacon's comparison of final causes to the vestal virgins; and perceive that they would be barren and unproductive of the fruits we are labouring to attain, and would yield us no clue to the comprehension of that law of conformity of which we are in quest. And so again with regard to the structural correspondences manifested in the locomotive members, if the principle of special adaptation fail to explain them, and we reject the idea that these correspondences are manifestations of some archetypal exemplar, in which it has pleased the Creator to frame certain of his living creatures, there remains only the alternative, that the organic atoms have concurred fortuitously, to produce such harmony.—But, from this epicurean slough of despond every healthy mind naturally recoils."

And as to the second question, it may be safely affirmed, that though there may be, and doubtless are final causes of which we know little, and adaptations in answer to these of which we know less; yet, on the whole, it is highly improbable that these could produce the uniformity which we behold Nor is it that the supposed causes are merely unknown; the analogy of the vertebrate and invertebrate animals, in many physiological respects, contrasted with their singular differences as regards form and architecture, would exclude the possibility of the most valid of such causes having any real operation.

The preceding may be regarded as the main position of the book, since on it hinges, not merely the rest of the treatise, but the whole homological anatomy of the skeleton. The magnitude of the truth thus laid down, it is scarcely possible to overrate, both as respects its nature and results.

The instances of design with which the visible world abounds have always been regarded as the best natural evidence of a Creator. As such, the divines of fifty years ago laid the greatest stress upon them; and all must remember how, in early life, even the importance of the subject and the value of the evidence, could scarcely prevent the mind from wearying of this tiresome repetition of one argument. And even when a clearer mental vision gave an additional value to the evidence, by pointing out its real worth—that it was not merely cumulative but reproductive—that each additional instance was not added, but many times multiplied proof—even then our feelings are more bewildered than heightened by this infinity of testimony—this "so great a cloud of witnesses." But now, how much more sublime is the prospect offered to us, and how much more nearly do we approach the arcana of nature! Not only do we recognise adaptation of means to an end, but of such means as bear to each other a specific relation of form, apart from that of purpose. Before, we only saw the use of certain portions of the vast edifice, or haply recognized their individual beauty; it is now that, for the first time, we seem to approach to some conception of their unity and relation to each other as a whole. And, as the architecture of man has been well defined as the union of beauty with habitableness, so, in this grander architecture of nature, we may find two precisely similar constituents—the general plan, and the special adaptation.

It might be expected that the novelty and importance of these conclusions would have created a considerable sensation. But we doubt whether this has been the case. Scarce a few months ago a work was published, containing views which possessed a like share of the novel and the striking, but which was otherwise of a very different character. And, although we do not intend to write vestiges of Vestiges, it is impossible to avoid remembering, that the celebrated vestige which horrified Robinson Crusoe scarcely created more surprise and astonishment in the so-called literary and scientific world than that slim octavo. Clever in hypothesis, impudent in assertion, ignorant of facts, it nevertheless achieved a brilliant bookselling success;—that is, it was universally sold and extensively read. The ordinary objections to that book we scarcely feel called upon to notice, having shrewd suspicion that people who shriek out about their faith do so because it is rather a fragile article. That it was Materialist in its tendencies, is little to us, since a progressively self-developing structure would be a higher instance of design, and would even more require the supposition of a Creator, than a stationary point of development. But we name it to point out that the book was a successful humbug, and that nothing but its anonymous character preserved its author from a kind of fame. The work before us is one of several by the same Author. Its facts are well ascertained, its inductions numerous, its reasoning regular and conclusive, and the result bids fair to be an invaluable addition to the philosophy of the age. But it is not at all a "Penny-Magazine road to knowledge"; on the contrary, it has the misfortune or fault of demanding thought, and requiring the connected attention of the reader; and hence we cannot help suspecting, that, compared with its antithesis, few have heard of it, seen it, read it, or much less understood it.

The treatise is divided into two portions. The first treats of the serial and special homologies of the limbs; and, in conformity herewith, mainly regards them as instruments, which, though peculiarly adapted to their different tasks, yet evince a common plan. Hence the higher vertebrata are chiefly adhered to; the fore leg is compared with the hind one, the solid hoof with the cloven. The modified metatarsus and metacarpus, with their still more complicated tarsal and carpal bones, are traced through various Protean disguises. As if by an enchanter's wand, confluent bones are resolved into their constituent elements, and severed ones re-united; and, in one word, the anatomy of the limbs in these better known animals is thoroughly compared, so as to establish the special bones answering to each other.

The second part attempts a higher flight,—the general homology of the limbs; or the general category of bones to which they are referrible. In the ribs of animals, it is seen that a typical vertebra is susceptible of so great modifications as to render it the likeliest place in which to seek for the origin of the limbs. That the limbs are not modified ribs is shown by the fact, that, however simple they become, as in the rudimentary wing of the apteryx, or the ray of the lepidosiren, still they are never directly attached to a vertebral centre, but rest on arches. These arches are next examined: in other words, the serial and special homologies of the scapular arch are explained. It is compared with the hæmal arch, formed by a true rib, false rib, and sternum, these parts being shown to correspond with the scapula, coracöid, and episternum of the bird respectively, the latter being then referred, through them, to the vertebræ.
